7/20/2011 V.1

TO OUR READERS.

OUR indefatigable critical friend, MISS PENELOPE POMEROY, wrote to us thus from Cackleton Hall:—

“What benefit am I to derive from the duty being taken off paper?—I mean as a purchaser of your Journal, *THE COTTAGE GARDENER*—for, as I told you, I shall never call it anything else. Do you mean to take off a penny, as the *Times* has done nobly?”

To which we replied—

“MADAM,

“We do not intend to take off a penny, nor even the smallest fraction of a penny. The removal of the Paper Duty is equal to about one farthing on each Number of our Journal; and as the price of paper has risen, we have no intention to reduce our price to twopence three-farthings, and incur even the loss of the recent rise in the cost of the paper on which it is printed.

“We added eight pages to our previous twenty-four in anticipation of the repeal of the Paper Excise, and we have made arrangements to secure a superior paper, and additional and varied artistical illustrations. We purpose to retain our price; and whenever our readers consider that we do not render an equitable return for that smallest silver coin of the realm, the time will have arrived for our exit.”

This reply was not satisfactory to MISS PENELOPE, and she rejoins—

“Just as I expected—just as it always is! The duty was taken off leather, and I still pay the same 16s. for my walking-boots to Mr. Leathersole, of Penzance. I should like to know what your other readers will say to your goings on.”

We are quite content to go before that Grand Jury; and we will anticipate as their return this extract from a letter written by a Clergyman, who, we think, will be accepted as their foreman:—

“We do not require the lowest possible priced paper, but we do want the best that can be had for threepence.”

We bow to that return, and we pledge ourselves to satisfy its requirement.

INDEX.

- ABDOMEN, HEN WITH ENLARGED, 110
- Abies, Douglassi at Kew, 140; of the Romans, 473
- Abrus precatorius, 105
- Abutilon insignis, 363
- Acacias, stinking and sweet, 129
- Acclimatation, the Society of Paris, 150
- Achimenes, pens for, 15; culture, 164; after flowering, 486
- Africa, productions of Eastern, 190, 210
- Agathæa coelestis variegata, 358
- Ageratum, wintering old, 505
- Ailanthus silkworm, 472
- Air admitting, 124
- Alyseum variegated, 356, 486
- America, natural phenomena in, 499
- American blight, 144, 360, 380, 406; not removed by frost, 320
- Amomum Clusii, 215
- Anemones done growing, 427
- Anigozanthus Manglesii, 476
- Annals, hardy and half-hardy, sowing, 15; hardy, for exhibition, 30; half-hardy in Waltonian-case, 80; hardy, sowing, 48; for bedding, 172; to stand the winter, 368
- Antennaria margaritacea as a bedder, 493
- Ants, expelling, 30; on Rose trees, 244; destroying, 285, 307
- Aphis on wall trees, 486
- Apian Notes, No. XII., 490
- Apis centuncularis, 82
- Apple, Ashmead's Kernel, 27; trees, ploching shoots of dwarf, 493
- Apples, as food, 361; in Oregon, 401
- Aquilegia caryophyllodes, 264
- Arabis, variegated, propagating, 15, 39, 426
- Araucaria imbricata injured by the winter, treatment of, 58; branches dying, 440
- Archway, plants for an underground, 265
- Arisæma præcox, 501
- Aristolochia picta, 180
- Arnebia Griffithii, 501
- Arnott's stove, 159
- Asarum virginicum, 205, 244
- Aspect for crops, 426
- Asphodel, bog, 380
- Auricula lovers, a treat for, 56
- Auricula, autumn management of, 376
- Auriculas of 1861, 174
- Australia, a fruit-producing country, 341
- Ayrshire Apian Society and Mr. Taylor, 288
- Azalea culture, 86
- Azaleas in greenhouses, 314
- BALANINUS BRASSICÆ, 140
- Balanus balanoides and cambricus, 482
- Bacant, laying two eggs, 270; characteristics of a Seblight, 328
- Bantams, hatching Game, 18; with egg-system inflamed, 31; dying suddenly, 110; Black, points in, 110; unable to crow, 150; with wry tails, 388
- Bark, medicinal, which Cinchona produces the best? 21
- Barkeria oelanelaulon, 160
- Barnacles, 482
- Basella cordifolia, 86
- Basil, forcing, 62
- Basket, wrong, returned from poultry shows, 245
- Bath and West of England Poultry Show, 207
- Beans, dwarf kidney and scarlet, 224
- Bedding plants, plotting out, 131; for spring, 173, 183
- Bedding-out arrangements, 162
- Bedding system v. mixed herbaceous borders, 377
- Beds under trees, 493; best of the season, 497

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 56° and 36° respectively. The greatest heat, 79°, occurred on the 7th, in 1859; and the lowest cold, 16°, on the 2nd in 1838. During the period 137 days were fine, and on 101 rain fell.

OUR ADDITIONAL NAME.

YES to the right—Noes to the left," said we, as we looked over the correspondence we had invited relative to our proposed alteration of title. When we came to the end of our division there could be no room for doubt, and we closed the counting of votes with "The Ayes have it."

Let it not be concluded, however, that those letters were few, or merely records of the writers' affirmative or negative opinion. Some were neutral and imparted the rough truth—"the title is of but little importance to us your readers;" some availed themselves of the opportunity to say what they required and what they took no interest in; and those who wished us, as one expresses it, "to be as ye be," argued strongly and earnestly.

One said, "People won't know you in a fine silk and satin dress. Stick to the corduroy and good Yorkshire broadcloth."

A second wrote, "I once tried to assist a man, as I thought, in extending his business; but I soon found all the money went for a new front, and in a few months a smash came."

A third declared, "The time-hallowed name of THE COTTAGE GARDENER is, I may say, 'familiar as household words' in many a nook and corner of old England. Why, then, change it? Why not preserve the unity of our future volumes?"

A fifth urged that "The present title is not quite so great a misnomer as at first sight appears. In addition to cottages 'where poor men lie,' are there not 'cottages of gentility?' Besides, make what change you will, your periodical will be called 'THE COTTAGE GARDENER' in spite of you, by buyers and vendors, till the end of the chapter—and may that be long distant."

A sixth argued—but we must publish our old supporter's letter entire:—

"The pure and simple title of 'COTTAGE GARDENER,' or as many called you, 'the Cottager,' was of itself very attractive. When you added the title of 'Country Gentleman' I did not think it an improvement of your nomenclature. But there, perhaps, was a sufficient reason, because you then entered upon pursuits and amusements which appertain to the 'Country Gentleman,' and I think that the majority of your supporters will agree that your present appropriate title will embrace all that can be collected in Horticulture, Floriculture, Agriculture, and, I may say, Omniculture, to say nothing of the 'Chronicles' of the Poultry Kings.

"I for one hope that you will not alter your pleasant name, although, by-the-by, you have just arrived at your twenty-fifth period—a time of life when ladies do begin to get uncommonly

fidgety about changing their names. I trust, however, that you are too well and happily domiciled to be influenced like some of them; and I hope you will not take it amiss if I heartily wish that you may retain unaltered your present attractive and homely name until you have doubled or trebled your present age, growing stouter 'typically' as you advance in years. I have little doubt that since your first appearance many a cottage gardener has, by his industry, perseverance, and your aid, become a country gentleman; but of this I am certain—that you have taught many a country gentleman the pleasure and advantage of being a cottage gardener."—W. W.

Now, strange as it may seem, these remonstrant and kindly expressed letters reconcile us to the addition to our title, for they do not foreshadow a single evil that will follow upon the change. We can assure our friends that we do not intend to dress in future "in silk and satin," and we shall stick as heretofore "to the corduroy and good Yorkshire broadcloth." Moreover, we are not "spending money" upon "a new front," nor do we think the addition to our old front will induce "a smash;" neither shall we be grieved by being called "THE COTTAGE GARDENER in spite of us," nor do we fear ceasing being "familiar as household words;" indeed every letter shows that we are associated with the "blithe blink" of their writers' "ain firesides," and that's a guarantee to our remaining there "to the end of the chapter." As to the "unity of future volumes" with their predecessors, we have made arrangements for that; and if we are "fidgety," like ladies of "twenty-five," to "change our name," it is only because we have a good match in prospect and the preceding approval of our friends.

The chief difficulty has been to select from the matches proposed. One old friend, writing from Cheltenham—that town of connubialities—placed before us no less than fifteen which be considered eligible, and very mature deliberation only induced us to accept the name under which we this day appear.

"But what is the real inducement to the change?" asks a lady; and this letter embraces our reply—it is from one of long experience in the literary world.

"I am greatly pleased to see that you are following the right policy—namely, increasing the size of your Journal as it prospers, and thus giving the public a share in its success: this will induce still further good feeling among its subscribers. I have long felt how entirely it has outstripped its original cognomen; and it is not conducive to your own interest to call it 'THE COTTAGE GARDENER,' when, in truth, it circulates more largely than any other journal among professional gardeners and the gentry who delight in gardening. And let me appeal to your self-esteem by observing that when quoted from, there is not much dignity in your appended name."—J. S.

Now, we have not a single additional reason to add to those stated by our friend; and having thus made our public confession, we will at once conclude with this monition by a high authority, "Be not given to change, but never hesitate from changing if the purpose be honest, and the object truth."

GROWING SPECIMEN PELARGONIUMS.

THE above woodcut is a representation of a specimen Pelargonium that was exhibited and presented to Her Majesty the Queen.

This picture will give our readers an idea how such a plant can be grown; and I think they will all agree that it was as good and as perfect a specimen as could be wished for. The method by which such a plant can be produced may not be so well known; but by tolerable care and earnest perseverance through all the stages and points of culture, any one possessing a good greenhouse, and a cold pit or frame, may grow one or more equally fine.

In order that any amateur or gardener having the means and the laudable ambition to try to produce such a specimen may succeed, I will state the results of my experience; and the first advice I would give them is that they lay this down as a law, like that of the Medes and Persians, to be unaltered or undeviated from—*Never let the leaves of plants intended for specimens touch the leaves of neighbouring plants.*

As they grow larger they must have more space, and that space will not be wasted; for one shapely, well-grown, and freely-bloomed plant will give more pleasure to the spectator with good taste than half a dozen drawn plants; though, as far as space is concerned, they may produce equally as many blossoms.

Another primary rule of almost equal importance is so to place the plants that every leaf shall have an equal share of light. It is well known that light is necessary to keep the leaves healthy and of an equally deep green colour. To manage this with the greatest ease, a span-roofed house running east and west is the best form. In such a house the greatest number of leaves receive their share of sunlight. In a lean-to house, the plants, in order that the leaves may all enjoy the same advan-

tage, must necessarily be turned round frequently, which, under ordinary circumstances, is a considerable trouble. This trouble might be in great measure avoided by placing each plant in a feeder with holes in it to let out the water; and the feeder and pot set upon a round, flat piece of wood set on a pivot, like the top of a music-stool. If this piece of wood had notches made on its edge, a long and strong stick with a flat, sharp end, could be inserted in one of the notches, and by pushing sideways the plant would, of course, move round. By this simple and cheap contrivance, a man would be able in a few minutes to turn round the plants in a good-sized house, thus saving a large amount of time; and he would also avoid any danger of breaking the leaves or branches with his arms—a danger that often occurs when the plants have to be turned round in the ordinary way.

Equally important for the health of plants is that each should have its due supply of fresh air on all favourable occasions. Fresh air is as necessary for plants as for animals. Where too great a number of plants are crowded into a house, they will be injured in health just like human beings. The gas they emit should be expelled from the house, and fresh pure air admitted for the plants to inspire; due regard being paid that the admitted air is not too cold, being warmed as it enters by passing over a heated surface, such as a flue or hot-water pipes.

Soil.—Every cultivator who has had any experience and exercises his thinking powers, soon finds out that different plants require different soils. Pelargoniums require a strong soil—that is, good sound loam, such as will grow Melons. The top spit of a pasture will answer well. Let it be carted home and laid up in a long ridge so as to expose as large a surface to the air as possible. Keep it clear of weeds, and let it be turned over two or

three times. To two parts of this loam add one part of two-year-old cowdung, well turned over frequently. Old hotbed dung treated similarly will do nearly but not quite as well. Then add about one part of river sand and bits of charcoal mixed. Let all these ingredients be kept in separate heaps till wanted for potting, then mix them in the above proportions and use them moderately dry. This compost should be used to grow and bloom the plants in. For the winter season use a small quantity of leaf mould instead of the dung. Fresh soil is always to be preferred, for old soil is apt to become cloddy and sour.

Procuring the Plants.—The best time to procure young plants is in April. Plants struck early the previous season are the best to commence with to lay a foundation for specimens. Choose such as are dwarf—that is, with a centre or main stem about two inches high, and branching from it three shoots as near each other as possible. If, however, the plant is stout and with leaves nearly down to the pot, then one or two shoots would do; but, then, these must be stopped in close to obtain three shoots of equal strength to form the frame of the future specimen.

Supposing the plants have to be procured from a respectable nurseryman at a distance—some one that grows specimens himself—you might safely leave the choice of the plants to him, only acquaint him in your order-letter with the purpose for which you require the plants. In 60-sized pots is the best size to commence with.

When the plants arrive place them in your greenhouse for a week or ten days to recover from the journey. In the meantime prepare your soil and mix it thoroughly, but do not sift it. Any rough pieces you may meet with lay on one side, they will be useful to put upon the drainage. Place this compost in a warm place to become aired and moderately dry previously to using. Look out also the proper-sized pots for this first shift. Large 48's, if the plants are strong and healthy, will be the suitable size. Have ready also a quantity of broken pots for drainage. If oyster-shells can be had they answer well to place over the hole at the bottom of the pot.

Potting.—Pelargoniums grown for specimens require potting twice in the year; the first potting being in the spring, and the second in the autumn. It is with the spring potting that we must first have to do.

All being ready, bring the young plants to the potting-bench, fix upon one to begin with, and put the drainage in a suitable-sized pot for it. Place first either a large crock or an oyster-shell over the hole; then lay a few largish crocks upon that, and then some smaller ones above them—the whole to occupy about three-fourths of an inch. Place a thin layer of moss upon the drainage, and upon that either a sprinkling of soot or charcoal dust. After that place a thin layer of the rougher parts of the compost, and finally a layer of soil. Then turn the plant out of the pot, pick out from it the old drainage, and loosen part of the roots, spreading them out over the new soil as much as possible. Then see that the collar of the roots is just below the rim of the pot, and fill in around the ball with the fresh soil, pressing it down gently as it is put in. When the pot is full give it a smart stroke or two upon the bench to settle the soil, level it neatly, leaving it about half an inch below the rim of the pot.

That finishes the potting of one; and when all are finished similarly, then give a good watering with tepid water and replace the plants in the greenhouse, bearing in mind my first warning—to give them plenty of space; also place them as near to the glass as may be convenient to give them proper attention in watering.

For a month or five weeks, whilst new roots are running into the fresh soil they will not need a large supply of water; but when the roots reach the sides of the pots, and the leaves and shoots are advancing in growth, then water will be required in abundance. They should never be allowed to flag. After a hot sunny

day let the plants, in addition to water at the roots, have a gentle dewing with the syringe: exercise discretion, however, in this point. No drops of water should be on the leaves the morning following: therefore the syringing should be used to the extent only that the water may be evaporated by the time the sun rises. T. APPELBY.

(To be continued.)

MAUVE AND MAGENTA.

THE beauty of these colours has often been dwelt upon, and now we have a most interesting treatise on their preparation from the pen of Mr. Robert Hunt, so well-known for his researches concerning the nature and properties of light.*

"A piece of wood and a lump of coal," observes Mr. Hunt, "have no particular resemblance to each other, but they belong to the same family—they are very near relations. The coal we burn, and which is dug from a thousand feet below the present surface of the earth, with most laborious toil and under circumstances of peculiar hazard to the miner, was once a forest growing in luxuriant beauty, in the splendour of a tropical sun. Myriads of ages have elapsed, mountains have been worn down, and their debris strewn over the buried forests. Hundreds of yards in thickness of sandstone and shale have to be pierced ere we reach our buried treasure, more valuable far than the "hoarded gold" of the enchanter Merlyn. In the depths and in the darkness of these rock formations chemical changes have gone on, resulting in the production of that coal which gives to our country her commercial supremacy, and to our ladies—Mauve and Magenta."

Whilst converting that coal into gas for the purposes of illumination we all know that a most pungently-smelling tar is produced; but, offensive as it is, "the chemist's magic art" has extracted from it several essences remarkable for their fragrance; and from the same black tar—to touch which was to be defiled—by a process of transmutation, the chemist has evoked a colour which has carried joy to the hearts of the Cardinals of Rome, and administered pleasure to the fashion-rulers of our own and other lands."

From the tar a blue colouring matter was first obtained, to which the name of *Aniline* has been given, because *Anil* is the name of a plant yielding Indigo. Aniline combines with sulphuric acid (oil of vitriol), taking the form of crystals which become red by exposure to the air: "and here is developed the secret of its producing the exquisite reds and purples of which we write."

"Mr. Perkins was the discoverer of the original Mauve. He was a student of Dr. Hoffmann's, and employed by that chemist to assist him in his investigations of the products from coal. The preparation of Aniline was described by Dr. Hoffmann, and he first showed that its presence could be detected by the violet colour it gave when treated with chlorine. This was the key to everything that has since been done, and it is not a little curious to see how the changes have been rung by the chemists on oxidising agents. A few examples will suffice:—

Salt of Aniline, with Bichromate of Potash...	Mauve and Perkins' Purple.
Ditto Bichloride of Mercury...	Magenta, and other Reds.
Ditto Bibromide of Tin...	Fuchstine, &c.
Ditto Nitric Acid...	Auriferous, Solfurina, &c.
Ditto Arsenic Acid...	Reds and Purples.
Ditto Peroxide of Lead...	Roseine.
Ditto Manganese Salts...	Pink, Red, and Purple, Solferina, &c.

This list might be considerably extended if there were any reason for so doing. Our purpose is answered if we have sufficiently explained the sources from which are now procured this class of charming colours, before which the boasted Tyrian or imperial purple must pale. The colour obtained from the shell-fish does not appear to have been a permanent colour; though costly, it was evanescent. The Mauve and Magenta are permanent colours. Light does not bleach them; the weaker acids do not stain them; the colour is dependent on the oxidation of the base of it, whereas, in nearly all other colours, the action of oxygen is to destroy the colour."

* This essay, entitled "Mauve and Magenta," is published in the 84th *James's Magazine*, the first Number of which has appeared this month. When we knew that the editorship of this periodical was entrusted to Mrs. Hall we expected that it would be characterised by a just appreciation of the beautiful, and a mingling of information with amusement. We are not disappointed, for it is one of the best of the monthlies.

REDLEAF AND ITS GARDENING.—No. 1.

As it is universally admitted that a bright day enhances the pleasure of all out-door gatherings, so does a fine neighbourhood improve the effect of well-directed skill towards embellishing a particular spot. As an instance of this, whoever has looked down from the Crystal Palace on the beautiful terrace below, without at the same time casting their eyes over the picturesque landscape by which that garden is surrounded? These natural advantages are so obvious, that we often look with pity on a good residence and grounds improperly placed for benefiting by the natural beauties by which it is surrounded. This defect, however, in no way affects the position chosen for the mansion and grounds of the place now under notice; for nothing possibly could be more judicious, even in a neighbourhood abounding in good positions.

The mansion and grounds of Redleaf, the seat of W. Wells, Esq., is on one of those eminences which form so pleasing a feature in the landscape of the south-western part of Kent. The ground is sufficiently undulating to be pleasing to the eye, without being too abrupt and precipitous to impede cultivation. Oak timber of the best description is sufficiently grown to give a clothed character to the district, without at the same time concealing the cultivated portion. The soil being a sort of yellow sandy loam, evidently impregnated more or less with iron matter, and resting on a sort of sandstone, which in some places crops out to the surface. But there are some stiff clays; and on the grounds at Redleaf, a natural slope facing the west consists of tolerable peat, or what in every sense answers as a substitute for it, so far as the welfare of the *Rhododendrons* and other things is concerned.

The mansion is a modern brick building, to which considerable additions have been recently made by its spirited owner. The approach is from the north-east, the principal fronts being on the east, south, and west sides.

The situation being elevated, the ground inclines rapidly to the west, and more gently and with some variation to the south, the east side being more level. The gardens and dressed grounds extend mostly to the south, south-east, and south-west of the mansion. The west side more quickly blends in with the park, which runs as a valley for some distance between the beautifully timbered ridges which flank it on either side. This valley extends for many miles, the view from this point being very interesting; the ridge forming the right flank presents many portions of its rocky surface to the eye, and the judicious mixture of deciduous and evergreen trees gives it a pleasing effect. The natural sloping ground uniting this ridge with that on which the mansion stands contains the natural peat alluded to, and is planted with *Rhododendrons* of good kinds, which seem so well at home that they ripen seed and sow themselves, plants of various sizes appearing amongst the Fern and other herbage, for this is not dressed ground. Some excellent specimens of *Cryptomeria japonica* and *Picea cephalonica* were growing amongst these *Rhododendrons* in luxuriant health, and some others of the *Pinus* tribe had been introduced with good effect, and with every prospect of their doing well.

In the foregoing outline of the natural features it will be seen that the most of the dressed ground is to the south of the mansion, and to the south-east and south-west of it; and although the whole, in farming phrase, may be said to lie within a compact ring fence, yet each department is separated from its neighbour by a sort of natural barrier, by which, on looking over the place, the visitor comes suddenly on some feature he had no reason to expect. These natural boundaries, or what, by a judicious assistance of art, seem to be natural divisions, often consisted of a projecting mass of natural rockwork, to which an excellent mode of appending other stones and tasteful planting gave an idea that Nature had done the whole. In another

Fig. 1.—REDLEAF—The English Garden.

place an irregular mass of Hollies forms an impenetrable screen between two objects, both in themselves good, yet advisable to conceal from each other. At the same time care has been taken not to allow these barriers to interfere with the good view of distant scenery that every now and then claims attention; for be it observed, that with the exception of a Dutch flower garden and conservatory attached, the whole of the other portions of the grounds present that easy natural style which ignores straight lines, perfect levels, and geometric figures.

The engravings taken of different views of the grounds, which

we shall place before our readers, in many instances fall short of conveying a just conception of this remarkable place, and the taste and skill by which it has arrived at its present condition; but they may, nevertheless, be acceptable as conveying some idea of the beauties of the grounds.

Fig. 1 is a view of what for distinction we may call the "English Garden," which consists of a large space of nearly a circular shape. The view being from the west presents a mass of natural rock on the left, or north side, with a fine *Magnolia* conspicuous in the centre, and an equally fine *Cryptomeria*

japonica, and other plants equally good. The whole of this space is well-kept turf with a walk surrounding it. On the outer side of this walk, on the south side, is a border of Roses backed by choice shrubs; and a series of oval-shaped beds (not shown in the figure) form a sort of chain on the grass on the inner side. The walk ascends to the top of the rocky eminence on the north side, and enters a summer-house (as shown in the engraving), the exterior of which presents some of the features of a Swiss cottage. Internally it is fitted up by the floors and walls being inlaid with woods of different kinds arranged in geometric patterns, but no varnish or French polish to destroy the character for natural simplicity which it is intended to convey, the roof being shingles. An inner compartment contains some fine specimens of porcelain and other rarities.

The position of the summer-house—on a ledge of rock over-

looking a garden containing some excellent specimens of Araucarias, Rhododendrons, with some Camellias and Azaleas on the approach to it—is beautiful in the extreme, as it is not crowded. The rock itself is in some places clothed with dwarf-growing Rhododendrons, with a little Ivy and other things, but in no instance crowded nor yet showing the equally objectionable feature of having been cut to keep it in bounds. Sufficient of the rock is shown to produce a pleasing effect, which is in some degree increased by a noble Oak tree shown in the foreground, and I have no doubt but in summer the beds will be rich with the choicest bedding plants; but at all times the scenery is attractive, and, secluded as it appears to be from the outward world, it is easy to picture the conjectures a playful imagination may bring up to second objects in themselves approaching so near the ideal of perfection.

Fig. 2.—REDLEAF—View from the drawing-room window.

The above is a west view from the mansion, which has, in some measure, been explained before. The valley, which near the mansion does not exceed a quarter of a mile in width, widens out in the distance, the extreme view being, I believe, upwards of twenty miles.

The rocky ridge on the north side near the house presents among other very noble trees some fine Oaks mingled with Scotch Firs, and now and then a Cedar of Lebanon jutting out in a manner that promises at some future day to rival the Oak in its proportions.

The grounds immediately in front of the mansion at this side present no particular object, but shelving down to the park seem to unite with it; the fence being in most places concealed

by the inequalities of the ground, a piece of water in one place forming the boundary.

The park, wisely, is not encumbered by trees in this direction, the ridges at right and left constituting sufficient shelter; but on the northern slope against a mass of rock, a rifle-butt stood out conspicuously, showing that even in this "happy valley" the laudable desire of uniting, in case of need, to defend our common country against all invaders is not forgotten, and, assuredly, no object can be more praiseworthy.

The natural hill or slope to the north of the house contains the peat earth before alluded to; and being planted with choice things, with occasional common ones as nurses, will at some future time be an important feature.—J. ROBSON.

(To be continued.)

EXHIBITION OF UNFORCED HYACINTHS.

MESSRS. ARTHUR HENDERSON AND CO., PINE APPLE PLACE, NURSERY, EDGWARE ROAD.

YESTERDAY, and during the last days of March, the good people of London had access to the first public exhibition of unforced Hyacinths on record. Miss Burdett Coutts and Madame Van der Hoop were hardly in their carriages from the Messrs. Cutbush's brilliant entertainment up at Highgate, when I heard of their resolve to meet some of their best admirers among the fashionables of the West End, at Pine Apple Place, on the following week, on free-and-easy terms, without forcing and without restraint. It is quite true that I was already "engaged" for a very different party on the south side of the Thames, as you will probably hear next week, and rejoice; but I could not resist the temptation of going to see the present fashion, the prevailing colours, and the style of getting up a *soirée* of Hyacinths, without forcing any one to it or for it. Nothing sweeter or more gay was ever seen in London before, and certainly nothing more charming. But believe me not, go and see for yourself.

This was my nursery for dressing and decorations when I first took to the fashions, and to ladies' colours and fancies. If you go you will find there every dress, and all the styles of dress, which I chronicled from the assembly at Highgate, are perfectly true to the letter and to the last shade of colour. You will also find on the south front of the exhibition-room and on the farthest half of it from the entrance, a complete assortment of

bedding Hyacinths, not in ribbon setting as at Highgate, but flanked with the best and gayest early Tulips. On the same front, and cross-cornered fashion, you will find that brilliant sameness of dress peculiar solely to that sweet class of bulbous flowers called Polyanthus Narcissus—one of the most beautiful and melancholy of all our classic names for flowers, and just as true as Ovid has made it melancholy.

The exhibition is held in the Lapageria-house, the Lapageria rosea covering the whole extent of the farthest end of the house to the extent of 20 feet in width, 9 feet in height, and runs along the rafters on both sides of the span roof to the extent of 15 feet more by the time it is in bloom. Over and above all that liberty a sucker-like shoot darts up here and there from the crown of the roots in early May, and runs its course to the extent of 20 feet by the end of August, and then blooms on like the free branchy growth of the head itself till the turn of the new year—the most splendid object in cultivation, and the coldest greenhouse is fit for such another display of hanging Lilies in bells and wreaths of the richest crimson softened down with tints of gold, and of vermilion in *pudibundus* slading. There is a large slate platform down the centre of this house, and others of the like material along both sides of it, with an ample passage all round; and the whole is filled with Hyacinths, Tulips, and Narcissuses alone, barring a thick, close

edging of Musk Minulus all round the middle platform; and a line of upright "greens" along its centre to the extent of 40 feet or so—consisting of *Araucarias*, as *excelsa*, *Cookii*, and the Brazilian forms of them; *Calitris australis*, the best of all "furnishing" evergreens, as no amount of bad usage, in confused passages upstairs or down, seems to harm it in the least—and what is more graceful out on the lawn in summer than a well-grown specimen of the graceful *Callitris*? Also *Dacrydium cupressinum*, with its drooping branches as if they were made of the Scotch *Lycopodium selaginoides*, and stuck on stems of *L. selago* itself—the latter the best remedy for all vermin which infest every variety and race of dogs, as I can testify from long experience: all these worked artistically from a centre plant of *Araucaria excelsa*, and all plunged in green moss.

All the double Hyacinths are said by this firm to do best in pots, boxes, or the open ground, "whereas the single varieties, when properly treated, rarely failed to reward the cultivator with fine spikes of flowers: therefore we recommend single Hyacinths for glasses, vases, China bowls, and for early flowering." And for all these purposes they give sound practical instructions and selected lists in their bulb catalogue, from which I have just quoted.

And now to the grand Show itself—and I will begin with *Double Red, Rose*, and *Pink*. *Comtesse de la Coste* is a first-rate deep rose. Duke of Wellington the same, with a lighter red. Groot Voorst, which I forced nearly forty years, is yet without a rival among double blushes. Another bedding beauty, and one of the best forcers—*Regina Victoria*, which you will find at the farthest end of the south stage, as I can now see it, is unrivalled as a waxy Peach Blossom of the finest shape; and *Waterloo* is still as good as when I first knew it—a dark rose red, and cheap to bed by the score.

Double Whites.—Same as I said of them the previous week, with the addition of *Triumph*, *Elandina*, and *Prince of Waterloo*—two very telling sorts, and very good for bedding.

Double Blue, Purple, and *Porcelain* (or very light caste of blue).—Old Laureus Custer, again only beaten in true blues by Sir Colin Campbell; but Rembrandt (shaded mauve) and Van Speyk are both up with Sir Colin. The rest of this section as at Highgate.

Single Red.—*L'Ami du Cœur* is one of the oldest and best forcers in this class, and I should think, a first-rate bedder, and is one of the cheapest. I shall never stoop to that vulgar mistake of preferring a new plant or a new colour to an old one equally good, and perhaps better, by being cheap enough for all consciences. But I have a dread of horrid foreign names, and here is the very worst of them for one of the best of the forcing red Hyacinths—*Diebitch Sabalskanski*. Madame Hodson is also a very fine light pink of great beauty. Amy, Florence Nightingale, and Mrs. Beecher Stow are still my own three greatest favourites in this class. Apellius, Cavaignac, Circe, Lina, Robert Steiger, and Schiller are all as good, or very nearly so.

Single White.—A gentleman of our Floral Committee put it to me at our last meeting thus:—"Which do you consider the best white Hyacinth?" "Madame Van der Hoop," I said at once. "Well," he said, "you are not far out—perhaps you are quite right;" but he considered Grand Vainqueur always as the very best. Now, if the two were before us for the first time and as new kinds, I would move to vote for a first-class certificate for Madame Van der Hoop; and if I carried it by a majority, and he moved for the credit for Grand Vainqueur, I would second him—that would be equivalent to saying they are both best. Dolly Varden, a blush; Elfrida, another blush; Gigantea, another the same; Grande Vidette, clear white; Orondates, the clearest white; and Victoria regina, fine waxy white, are all first-rate flowers in this class. Of single Lilacs with mauve tints—Dandy and Unique are the best.

Single Blue, Purple, and *Porcelain*.—Enrieus is still the best forcer in this beautiful group. Argus, Baron von Humboldt, and Baron von Thyll the next best. Charles Dickens is very fine, and so is Couronne de Celle. Mimosa is superior to the old *L'Ami du Cœur*, which is one of the best blues for forcing and flower gardens; and the Porcelain Sceptre and General Havelock, the next to Mimosa, both being first-rate.

Of Crocuses—David Rizzio, Prince Albert, and Ne Plus Ultra were the best purples. Queen Victoria the best white, and Majestouse the best in Sir Walter Scott's strain, but not much larger than Sir Walter this time.

Narcissuses—Superbissima was the best yellow pale perianth, and deep yellow cup; Queen of Yellows next best, and both

superior to our old favourite Soliel d'Or. Gloriosa and Queen Victoria the two best whites with yellow cups, and both superior to the old Bazelman major, which held the sway so long. Maximus, or Yellow Trumpet, is a splendid thing to force and to make large beds of (it is not of the Polyanthus race); and Ajax bicolor, major, minor, and minimus or pusillus, are edging plants for spring beds which I have used for years, and found there the true pusillus, which I had been long looking out for. I still want Narcissus papyriferus with six to eight flowers on a spike—one of the earliest, and would pass for a Polyanthus Narcissus. A gentleman told me last year that Mr. Stephen Brown, of Sudbury, Suffolk, sells it, and I ordered Mr. Henderson to procure it for me. How strange that such a beautiful flower should be so little known, and so much neglected! Mr. Arthur Henderson had *Cunningia trimaculata*, with which I was familiar in 1823 and 1824 as a *Conanthera*, and every other bulb you could mention from that day to this, all as cheap as Potatoes, and yet country gardens are starved out of them from sheer ignorance of the existence of such things; while Stinging Nettles are run after if there is a variegated spot on a leaf of them!

Then the summer of 1859 had put the spell off the Russian and German Ivy plant *Ipomœa hederifolia*, and it flowered out of doors against a south wall—a pale lilac *Convolvulus*-looking flower, just as Plumier painted it. When Mr. Masson travelled in Russia and the north of Europe, and wrote his notes six or seven years back, he said the nobles in Russia had backgrounds of Ivy to all their drawing-room decorations of flowers in the dead of winter; but nobody in London could understand how they managed their Ivy, and, being then out of humour with the Russians, they did not care much about the loss of their way of growing the Ivy. But when I was last at the Clapton Nursery I met a nurseryman there from the north of Prussia, and we rode in the same bus, and there I got at the secret. He said the Ivy was never so used in as far as he travelled on his yearly rounds in Russia. But there, and with them in Germany, the *Ipomœa hederifolia* had been time out of mind trained in narrow boxes for in-door decorations in winter; and by mixing it with flowers, and backing flowers with it, nothing in its way could possibly excel it. No matter how hot, or how dry was the air of their living-rooms, the "German Ivy," as he called it, was sure to be at home there, or elsewhere away from the frost; train it up inside their double-glazed windows, or over their mantelpieces, or against the walls anyhow, no hurt or harm, or insect ever went near it. "But you in this happy England," he concluded, "have no difficulty in greens; for everything keeps green with you, and you have no need of them." But you heard last week of the Highland welcome which this same German Ivy has met with in New York, where our Ivy has no chance against the frost; and may we not after all have a leaf out of their books?

What would you say to a *Euphorbia jacquiniiflora* trained to a trellis which had been previously Iried all over as thick as the ruins of the monastery of Monkbarrow, to stand in the front drawing-room against one of the paper panels, and to last there for six weeks in splendid bloom in the dead of winter? Or how would it look in lieu of muslin curtains across the bottom of the window in your office, or rather in place of the everlasting network blinds you are so safely screened behind? Would not a thick screen of Ivy leaves, trained from a handsome box below the sill, do for blinds? and might they not also be got up higher to serve for curtains at the same time, and put you in mind of the country in the midst of London?

But what most struck me in the Pine Apple Place Nursery was the high style of culture given to all the plants, no matter where placed; the specimen stove plants in a house at the upper end of the nursery, and the house for the greenhouse specimen plants, together with the show-house, as you enter the gate, are the three best evidences of good cultivation and arrangement I ever saw so early in the season; and I should say that in about six weeks the New Holland house alone would be worth a journey to London to see it in bloom. But that would be the least part of my object, as I had so often seen all the best of them in bloom: it is the style, the potting, the outlines of the plants, their different sizes, their health, and the absence of all traces of insects that would amaze me, after knowing all that could have been done during the lifetime of the father of the young men who now attend to them, and the whole collection is on the self-same footing.

The *Ficus repens*—a very different plant from the *repens* so called, against the back wall of the specimen stove, sticks to it

like Ivy, and hangs out from it as regularly as the ears in harvest, just like Sweet Bay leaves—is the finest screen for a back wall I ever saw. Here everything good and handsome is grown as a specimen, just as if it were for the Show. *Medinilla magnifica* in full bloom—and if the Messrs. Veitch had never introduced another plant, they might be proud of their success through this plant alone. *Euphorbia jacquiniiflora*, lots of, in bloom. *Gordonia javanica*, an excellent forcing Tea plant in full bloom. *Ardisia undulata*, plants by the hundreds, and the white or yellow-berried kind of it grafted just as freely, and all for decorating the dinner-tables in London with their holly-like berries. One grower near London grows one thousand *Ardisia undulata* each year for the London market. *Hippeastrum reticulatum*, which I feared was dead and gone “lang syne,” was there sure as certain, and not so high-priced as one might think, considering it is the best and the scarcest of all our ancient families. We had a rumour with some one in our early days about the reticulate of this very plant, he saying the reticulation, or the network-like veins, were in the leaves; and we the contrary—that the net was on the flower, which is of a light crimson colour, with a white star round the eye, and a broad white longitudinal band down the centre of each leaf, and a large pot of it would make a better variegated specimen for exhibition than many that have been tried. The white variegated *Agapanthus* is getting a lift here to hurry it on in growth, being a very slow goer, but a beautiful thing when of a large leafy size.

Begonias all of the best sections, and the crosses from Marshallii by Rex, have a fleece of snow-like spots all over the leaves on both sides of the milky way—the zone or sonata of our “Proceedings.” I was very much gratified to hear Mr. Henderson say that the report of this class by Mr. Moore, and the selection by the Floral Committee, were both most excellent and trustworthy; but we owe it all to the high style in which Mr. Eyles and his men got them up for examination; and equally so to hear the Baron Rothschild in his garden, near Paris, had large edgings of both Rex and Marshallii last season, and that they were the most exotic sight on the whole continent.

The greenhouse specimen-house is full of all the best leading plants recently potted and making rapid growth—really a sight of itself. A large specimen of *Brachysema longifolia* is a perfect mass of scarlet pea-blossoms, and is one of the few plants of that style which sets its flower-buds in the autumn, and may be slightly forced to come in in January, or any time in the spring. *Pultenaea subumbellata* in full bloom; *Loddigesia bellidifolia* the same; *Acacia rotundifolia*, very slender and drooping, is a fit subject for hanging-baskets, and such are in great demand; *Aphelaxis*, of sorts, bursting their rich, shining, crimson flower-buds, for “everlastings;” *Epacris ceriflora*, a white, early-flowering species, the hardiest and most useful of the family, as it may be forced very gently to come in any time in winter, and all of them may be forced the same way from November; *Acacia Drummondii*, in whole dozens, and all bloom as free as Crocuses, but never seed unless the plant is half-starved, and not fit to be seen; *Platylobium parviflorum*, one mass of yellow and brown blossoms. In another house were a lot of *Araucaria Cookii* recently sent over by Mr. Moore, of the colonial botanic garden at Sydney. When I first knew Mr. Moore he was a little fellow in the seed-shop at Pine Apple Place, and getting no more shillings a-week than he now gets hundreds a-year, and richly deserves them for his services in the good cause. This house was full of rare useful things, from the *Arabis variegata*, in hundreds, for edgings to *Blandfordia nobilis*—one of the finest Australian bulb-like plants. *Anopterus glandulosus* with its long upright spikes of *Arbutus*-like blossoms, which come early in spring; *Dyckia rariflora*, a scarlet representative of the American Aloe, which would do for an age in a No. 48 pot, and bloom every year of its life; *Nerines*, *Pentlandias*, *Trilliums*, *Camassias*, *Coburgias*, *Alströmerias*, *Cladanthus*, *Phædranassa*, *Zephyranthes*, *Gloriosas*, *Griffimias*, *Hæmanthus*, *Cypellus*, *Calochortus*, *Cyrtanthus*, *Ismenes*, *Lycoris*, *Habranthus*, *Rigidellas*, *Tritelejas*, *Bomarea*, *Bravoa*, *Milla biflora* at last, *Brodieas*, with *Caladiums*, *Crinum*, *Amaryllises*, *Cypripediums*, *Eucharis*, *Vallota* and many others; and all with more or less kinds of species and varieties of the first order of merit; but they are not bedding plants, and therefore not sought after, but by a few knowing customers who delight in having some of all the best flowers of the creation.

In a large three-spanned-roofed house were the *Gloxinias* all showing for bloom to meet the early demand of the London season. Great quantities of the Indian Fig, *Ficus elastica*—the aristocratic London plant for the front drawing-rooms; all the finer Cannas, of which bicolor and iridiflora—the former for

its leaves, the other for its splendid flowers—are the most deserving; *Hibbechinum aurantiacum*, a weedy-looking plant, with the richest of all yellow shades of colour; the *Vitellinum*, or yolk-of-egg colour, and even the true Magenta colour—the only plant we yet know which produces the true Magenta, and that is the colour of the flower-stalks of the American Poke, or *Phytolacca decandra*—a very old shrubby plant, which every one who raises seedlings ought to grow to compare his seedlings with in the autumn, as Magenta is now the great want of the day.

The old stove is brimful of Ferns and fineries, of which *Platynerium grande* is the most out-of-the-way; but I shall have a new start with it shortly—a far better way of doing it than at present. In the old Orchid-house is a large planted-out climber, which few have yet done half so well or even know of. It is *Clerodendron speciosissimum*, the fellow to splendens, but requires a very different treatment: but I should get what I often require if I were to enlarge on it at the tail of a story like this. *Bougainvillea spectabilis*, the highest mauve; *Dracenas* by the scores for dinner-tables; *Caladiums* by the dozens. But who can bide all this? Let me, however, say of a recent cut from Paris, that *Dracena congesta* is there seen in all their best shops and houses, as the *Acacia lophantha* is seen down at Canterbury, the Indian Fig in London, or the Aaron's Beard in country cottages—a universal favourite, and graceful-looking Pampas-Grass-like leaves. Also *Wellingtonias* out in bushel baskets 2 feet across, to be planted baskets and all, and no hurt or cramping to the roots. I think we owe this most excellent plant to Mr. Rivers, who, with M. Naudin, calls “geothermal” earth *heat*, while the true meaning of the word is just what we all want—and that is earth *warmth*. D. BEATON.

ICE-HOUSE VENTILATION.

HAVING observed the remarks upon ice-houses in THE COTTAGE GARDENER of March 19th, “A SUBSCRIBER” would feel much obliged by having some information upon the best means of ventilating an ice-house, which is constructed thus:—The well is sunk about 5 feet, surrounded by two brick walls with a space between them. That part of the outer wall above the surface, about 5 feet, is surrounded by a bank of clay. The well is about 10 feet across. The roof is very steep, and has about a yard thickness of straw upon it. The ice is broken up small, and piled up into a cone. The ice is placed upon small pieces of wood, so that there may be a cavity underneath: at the bottom there is a trap-drain, to avoid having a current of air from below. The well is lined with straw, so that the moisture may run down the straws to the drain. There are three doors facing the north. The spaces between them are filled up by sand. No air can enter. Could anything be done now that the ice is in? It would be a great convenience if any method could be advised so as to avoid removing the sand every time the ice is wanted—and last year there was considerable waste.—E. T.

[The sand and straw are the causes of the loss of ice. If iron hurdles which would keep out cats and dogs were where the doors now are, and all the sand were removed, and a small opening were made in the highest part of the dome of the roof, with a cap supported a little above the opening to prevent the rain from getting in, a current of air would pass from the outer door (and no second door is at all necessary) through the passage and out of the top of the dome. Then there should be 6 inches of very loose straw put on the top of the ice to keep the current from the surface—not between the ice and the brickwork, which is a wrong idea altogether, and has melted ten times more ice than ever it could save. Every inch of the straw is soon full of confined air damped to the point of saturation, and that is what melts the ice. The longer and the drier the passage is, the faster the vapour is carried off from the ice. Dry air in rapid motion has a thirsting power of sucking up damp, and damp warmed by confined air into vapour is always, and in all places, more destructive to ice than the blast of a furnace. That we have ourselves proved over and over again; and we have cured one of the largest and worst ice-houses in the kingdom by the same means as we now propose to you. For ten years previously the family derived no more use of the ice in that ice-house than the keeping of things which would not keep so well in the larder. We heard of the airing plan having been adopted by some clever scientific architect, who

built a famous ice-house for a large family above ground. The gentleman for whom that house was built told us the story, and the reasons of the man of science, and that led to our own ideas and practice of some years being cast into the current; and some other fixed notions of the age might well be spared to go the same way, but none more so than the old notions for keeping ice. Ice-houses should never have been built under ground at all, that is just their ruin; and if they could be built on cradles above ground, like corn-stacks, and then sufficiently covered with non-conductors, that would give the least waste of all. Ice-stacks built on "flats," made in the face of a steep bank facing the north, is the next safest plan, and is the most practicable now; but a stack of ice at the bottom of any high ground is in the next worst position to a well of ice in the bosom of the earth.—D. BEATON.]

THE SPRING MANAGEMENT OF CARNATIONS AND PICOTEEES.

MR. BEATON is quite right in saying that the Royal Horticultural Society, since the formation on a broad and liberal basis of the Floral Committee, now, for the first time in its history, has the advantage of real practical florists; and I quite agree with him that great profit may be derived from the mutual intercourse of such and gardeners in general. Our own pages show how much this interest is increased, and that one kind of fancy encourages another. I know it has been the fashion with some (I am not sure that I do not recollect some sly tilts of D. B. himself) to decry the rage of florists for shape and smooth edge, and the other points of a florist's fancy; but let two flowers be placed together, one indifferent in a florist's qualities, the other up to the mark, and I am quite sure it will be at once seen that shape, &c., have a good deal to say to beauty. Look, friend, at Mrs. X., with a figure somewhat like a sack tied in the middle—is she as good an object to feast one's eyes upon as Mrs. C., with her slight ladylike figure, even though her rival may have plenty of colour both on her face and in her attire? And so form, I say, in the first instance, then colour afterwards.

This much by way of preface to a few remarks on the spring culture of a flower, which owes no little of its beauty to the zeal and discriminating taste of those hybridisers who have said we must have form—who have set before themselves an ideal, and have worked up to that until little is left now to be desired in that respect. It has obtained size and thickness of petal, smoothness of edge, circularity of outline and depth of bloom; but, of course, after much toil and continued weeding of inferior varieties from the list. The last season was as unfavourable to them as it was to everything else. Great difficulty was experienced in getting the layers to root; and Mr. Turner, the largest grower of them in the south of England, has hardly sent out any, I believe, until the spring, allowing them to root better before doing so: consequently those who wish to begin growing this very sweet and beautiful flower, can have no better time for adding to their collection a few favourites than the present.

Let me suppose that these have been procured (I shall add a list of a few good ones in each class), and that an amateur wishes to commence their growth. Having thus caught your hare, the next thing is to see to the cooking thereof. The most certain method is to grow in pots, for wireworm and other abominations are likely to destroy your rising hopes if grown in a bed. Pots about 9 inches across are the best. Unfortunately, I have learned by bitter experience that larger-sized ones are a nuisance in every way, and do not grow the plants as well; the only advantage they possess being that they offer a broader space to layer in. The pots ought to be quite half filled with coarse drainage, and then a little moss placed on top of that. The compost should now be put in. This ought to consist of good sound yellow loam, well-rotted frame manure, and leaf mould in about equal parts, with a little road grit to keep it open. Let every handful of the compost be passed under your hand and eye, and carefully look for the foul form of a nasty yellow grub, called a wireworm, which has a disagreeable habit of getting into the centre pith of the plant, eating out all its heart, and then decamping in quest of another. Immolate him without mercy on the shrine of Flora if you catch him. This being done, fill in your pot nearly full with compost, and then prepare to put in your plants, a pair in each pot. If these have been kept in single pots all the winter they will turn out all the

better, as the less the roots are disturbed the sooner they will lay hold of their new quarters. Now fill in with compost, give the pots a good shake, and then water either with a fine rose or a syringe. They may then be placed for a week or two in some sheltered position until they become established, and after that removed to some open place. The centre of the walk I find to be as good a place as they can be in. When the flower-stem commences to run up they should be tied to stakes—one in the centre of the pot will be sufficient. Weeds must be carefully taken out, and, if the weather be dry, watering be attended to; and as the summer advances, I hope to say something more with regard to their management for blooming.

They have been divided into various classes. Carnations into scarlet bizarres, crimson bizarres, pink and purple bizarres, purple flakes, rose flakes, scarlet flakes; and Picotees into red, purple, and rose-edged ones. By-the-by, I have noticed some (to those unacquainted with them) most misleading advertisements of seeds under each of these different heads, as if they were to be had *distinct*—whereas one pod of seed is just as likely as not to produce every one of the kinds named, so it really only answers the purpose of selling a dozen packets of seeds instead of one. I have also remarked seeds of Pelargoniums advertised with the names of the flowers the seed has been saved from. But unless these have been carefully crossed, their having one parent good is very little use, and no guarantee whatever in any case that the seedling will partake of the parents' character.

I now give a list of some really good kinds, and such as are of good constitution; my object being to encourage beginners, and not to set them to grow varieties which baffle even old cultivators.

CARNATIONS.

Scarlet Bizarres.

Captain Thompson (Puxley)
Mr. Ainsworth (Holland)
Oliver Goldsmith (Turner)
William Pitt (Puxley)

Pink and Purple Bizarres.

Falconbridge (May)
Lady of the Lake (Hale)
Sarah Payne (Puxley)
Shakespeare (Puxley)

Crimson Bizarres.

Chancellor (Puxley)
Orestes (Puxley)
Premier (Puxley)
Sir George Brown (Puxley)

Scarlet Flak s.

Defiance (Puxley)
Mars (Puxley)
Sir H. Havelock (Puxley)
Sportsman (Hedderley)

Purple Flakes.

Ascendant (May)
Earl Stamford (Elliott)
Mayor of Oldham (Hepworth)
Squire Trow (Jackson)

Rose Flakes.

Aglaia (May)
King John (May)
Poor Tom (May)
Nymph (Puxley)

PICOTEEES.

Red-edged.

Ada Mary (Smith)
Cedo Nulli (Headley)
Dr. Pittman (Turner)
Sametta (Smith)
Mrs. Norman (Norman)
Ne Plus Ultra (Headley)
Penelope (Turner)

Purple-edged.

Amy Robsart (Dodwell)
Bessie (Turner)
Eliza (Payne)

Purple-edged.

John Linton (Headley)
Rival Purple (Headley)
National (Holland)
Lord Nelson (Norman)

Rose and Scarlet-edged.

Alice (Hoyle)
Crystal (Smith)
Lady Greville (Turner)
Rev. A. Matthews (Holland)
Mrs. Barnard (Barnard)
Venus (Headley)

THE LITTLE MARKET-GARDENER;

OR,

HOW TO CULTIVATE AN ACRE OF LAND WHEN PROFIT IS THE CHIEF AIM, AND SHOWING HOW A FAMILY MAY BE SUPPORTED, AND SOMETHING PUT BY FOR A RAINY DAY.

POTATOES.

As soon as March comes in it is time to plant the second early Potatoes. The best sorts that I know of are, what we call in Shropshire, Knapsacks, Early Flourballs, Sportsmen, and Liverpool Merchants. Having purchased about fourteen pecks of the best sorts you can procure, mark out fourteen rods of the land that you have double dug, and plant the Potatoes 2 feet from row to row and about 8 inches or 9 inches from set to set in the row. You may plant them how you like—with spade, fork, or dibble, so that you do not plant them too deep. About 4 inches is deep enough for this time of year, and I believe this to be as good a time as any; and I have planted them at all times from October to July. In 1856 I obtained seventy-two bags to the acre from Potatoes

planted the 22nd of June. Do not plant large sets, or whole Potatoes, unless they are very small. If you can get them, small-sized Potatoes that will weigh about 1½ oz. each are the best, cut through the middle, minding to cut through the crown. If you have large Potatoes do not let the sets have more than one good eye each, there being nothing worse for the Potato produce than too much haulm. I intend writing a very long chapter upon Potato growing when I am not quite so busy. I will then tell you how I grew thirty-one pecks to the rod in 1859, and eighteen pecks to the rod upon the same land in 1860, some of the Potatoes weighing 1½ lb. each. I placed thirty Potatoes in my window that weighed 25 lbs., and that same land has had Potatoes on every year for twenty years.

LATE PEAS.

Any time in March, or the first week in April, mark out two rods of land, not too close to hedges, and dig about one ton of good manure into it. If you put them in with the spade, as I advised for the early Peas, let the rows be about 2 feet apart, and do not sow them too thick in the rows. I put mine in with a dibbling-iron, the same as is used for dibbling Horse Beans, and they do better in that way than any way I have ever seen. I make the rows about 14 inches apart, and the holes about 3 inches or 4 inches from each other, and about 2 inches or 3 inches deep, and drop the Peas one in each hole. The best sorts that I have grown are the *Bellamy's Early Green Marrow*, the *Champion of England*, and the *Victoria Marrow*.

PARSNIPS.

These should be sown as soon as possible in March. Let the land be double dug, the same as advised for Potatoes, not too close to trees or hedges: and if you have a good tank for the soapsuds and such sorts of slops, pour a good bucketful or two into the bottom of every trench. Mark out the land, about one rod, into four-foot-wide beds, and sow four rows upon each bed. Make the rows with the back of a rake just deep enough to cover the seeds, and sow a row of Radishes between each two rows and up each outside.

CARROTS.

Carrots may also be sown in March, if the land is not too stiff or wet; if it is they would be better sown about the middle or latter end of April, and then dig a good dressing of charred rubbish into the land, and mind to sow the seed as soon as the land is dug. If it is light or sandy land it does not matter how soon in March you sow them. Mark out one rod of land in the middle of the garden and away from trees; dig it deep and well, and if you put a good dressing of soot and dig it in, so much the better. Mark it out into three-foot-six-inches-wide beds, and sow the one half with Early Horn and the other half with any large sort you like best. I always find the Altringham to sell best. Sow five rows of Early Horn upon each bed; but four rows will be thick enough for the large sorts, and you may sow a row of Radishes between each two rows of the large ones, but not between the Early Horn.

ONIONS AND LEEKS.

Early in March mark out six rods and a half of land almost anywhere, so that it is not too much shaded. Put a good dressing of manure upon half a rod that is the farthest from the outside for the Leeks; dig it in deep and well, mark the ground out into three-foot-six-inches-wide beds, and sow the Leeks broadcast, and not too thick. Then dig the other six rods. Then take about three tons of very rotten manure (after you have marked it out into three-foot-six-inches-wide beds, and trod them down pretty firmly), and spread upon the beds regularly and evenly. Beat it down with the back of the spade; then sprinkle it over about half an inch, or 1 inch, thick with soil out of the walks. Mark out five rows upon each bed, and sow about 1 oz. of Onion seed to every 10 yards length of bed.

BROCCOLI, SAVOY, BORECOLE, AND CABBAGE PLANTS.

About the middle of March mark out three rods of your best warm borders to grow plants for sale—such as Broccoli, Borecole, Savoys, and Cabbages; dig it over, and sow the seeds as you go on, not too thickly. If the land is very poor, give it a good dressing of charred rubbish.

EARLY POTATOES.

About the last week in March will be time to plant your Walnut-leaved Kidney Potatoes. Plant them with the spade

about 18 inches from row to row, and about 7 inches or 8 inches from each other in the row, laying them carefully in the trench with their sprouts upwards, and mind not to break the sprouts off. All that are not nicely sprouted should be put on one side, and planted by themselves, to grow seed for another year.—THOS. JONES.

(To be continued.)

THE CENTRE BED OF A FLOWER GARDEN.

THE garden is about 110 feet by 60 feet, and enclosed on the east and south by a wall covered with Magnolias, &c.; on the north by a range of hothouse, conservatory and vinery; on the west by a wall with arches, through which the roseray and park beyond are seen. There are about forty-eight beds of various forms converging towards the centre, and advice is wanted as to whether the centre bed should be formed of three tiers, what is the best to form the outside of each tier, and how they should be planted to give the best effect through the summer? The bed may be 10 feet across each way. Or would a wooden or wire stand of lower and upper baskets be recommended in preference?—ROSA.

[The centre bed of so large a flower garden as yours, where forty-eight beds converge to the middle bed, must not be raised in two or three steps as you contemplate, but be as nearly flat as possible, say a ten-foot-in-diameter bed, to be raised 6 inches in the centre. Neither must it be planted with scarlet or yellow flowers, nor strong pink-coloured nor purple flowers, nor have any kind of standard plants in it; and the reason is that a tall raised centre, or a centre of very strong colours, would arrest the eye, or attract it too much to the prejudice of all the off-side beds viewed from any point all round it. The best way to plant your centre bed is, either to fill it with mixed flowers of all colours and edge it with variegated Alyssum, or with some variegated plant; or to plant it with one, two, or three kinds of variegated Geraniums in separate rounds, and to edge them with the dark blue *Lobelia speciosa*.]

ARRANGEMENT OF CROCUSES.

MANY of your readers besides myself will thank Mr. Beaton for his remarks on the Crocus. I have several beds done somewhat in the manner described, but I shall now be able to improve them. For instance: I had used in some cases the *Cloth of Gold* yellow, not being aware it was so much earlier than others. By the time the others are in their prime this is going off, and the effect is much impaired. Now that I know the bulbs can be moved without harm immediately after flowering, I shall alter this.

Nothing in the whole world of gardening delights me more than the pot culture of the early bulbs for in-door decoration. For a mere novice I think I am tolerably successful; but I have a difficulty. The Crocus bulbs always rot away after producing four or five little bulbs. The Tulips and Narcissi divide themselves into three or four, and neither these nor Crocuses will flower next year. Does this arise from bad management? Can it be obviated? I was surprised to learn there was a larger and finer Crocus than *Sir Walter Scott*; but I shall look forward to a trial of *Majestuse* next year. I had upwards of nine dozen blossoms from five bulbs of the *large yellows* in one pot. Is not this an unusual number? It was a blaze of beauty.—H. A.

[Of course, in planting lines or beds of mixed Crocuses, all the kinds should be in bloom at the same time. We cannot give an opinion as to the cause of the bulbs decaying until we know the nature of your soil and the mode of culture.]

I AM very much dissatisfied with the manner in which my gardener has planted the Crocuses, and I have seen with great delight a chapter on the "Arrangement of Crocuses;" but when I came to study it, it seems to me so confused that I can make nothing of it. You will be conferring a great boon on a great many of your readers if you would just give us a few intelligible hints. Mr. Beaton is generally sufficiently intelligible, but this seems to have been written in a hurry.—A SUBSCRIBER AND ADMIRER.

[Begin with the A, B, C of planting Crocuses, and let A stand for white and all shades of white, B for yellow, and C for purple,

and plant them thus—A, B, A, C, A—B, A, C, A—B, A, C, A. That is how to plant Queen Victoria (A), Dutch Large Yellow (B), and Prince Albert (C). There is a white on each side of the yellow and on each side of the purple, and that rule is to apply to any number of shades of all the Crocuses.

Sir Walter Scott is a white, with streaks in it: therefore call it A1, and plant it, like A Queen Victoria, at regular distances.

Majestense is a white, with more streaks than A1, call it A2, and plant it also at equal distances, as on each side of yellow and on each side of purple.

Marie d'Esosse is a white, with most streaks, call it A3, and plant it at equal distances in your row. If you have a large yellow and a small yellow, mark the latter B1; and if you have

three or four shades of purple call them all C's. The best of them is plain C, second best C1, third best C2, fourth best C3. See that all the four are at equal distances apart, each with a white on each side of it. Then, if your row is a mile long, you have double the number of whites in it, no kind is in two patches together, and every individual kind stands at regular distances along the line.]

PARISIAN MODE OF ROASTING APPLES.—Select the largest Apples; scoop out the core without cutting quite through; fill the hollow with butter and fine soft sugar; let them roast in a slow oven, and serve up with the syrup.

NEW PLANTS FROM JAPAN.

SCIADOPITYS VERTICILLATA—THE PARASOL FIR.

FOR nearly three hundred years the empire of Japan was till lately closed against all European nations except the Dutch, and it is consequently through them or their employes that any information has hitherto been acquired respecting this remarkable country, its people, and products. Had that communication been free and general, our knowledge would have been much more extensive; and we might, through a people so enterprising and intelligent as the Dutch, have become possessed of as complete a history of Japan as of any other region of the world. But even the Dutch enjoyed only a limited intercourse, their trading being confined exclusively to the harbour of Nagasaki. In consideration of this permission to trade with the Japanese, the Dutch were compelled to send an embassy annually to the Imperial Court at Yeddo; and it is to the scientific men who accompanied this embassy, that we are indebted for what little knowledge we have of the plants and natural products of the empire. Those who have written on the subject have generally been employed as physicians to the Dutch embassy. Kämpfer, a native of Westphalia, arrived at Nagasaki in that capacity in September, 1690, and, after residing two years, left in November, 1692. Thunberg, a Swede, pupil, and subsequently successor to the great Linnaeus, was also attached as physician to one of these embassies, and arrived at Nagasaki in 1775. To him we are indebted for a pretty extensive knowledge of the plants of Japan; but beyond dried specimens of the plants he describes in his "*Flora Japonica*," neither he nor Kämpfer contributed any-

thing to the living collections in European gardens. Dr. Siebold, also a physician, who has resided several years in Japan, has hitherto been the only European who has introduced living plants of Japan into Europe; among which some species of

Lilium and of *Clematis* are familiar examples.

The circumscribed limits to which the residence of all these men was confined, operated against their acquiring a more extensive knowledge of the country and its productions; and hence it is that some of the grandest of the trees and shrubs of Japan remained unknown except by reputation. It has therefore, been reserved to the enterprise of Mr. John Gould Veitch (son of Mr. J. Veitch, of the Exotic Nursery, Chelsea), a gentleman young in years, but mature in knowledge and experience of plants, to enjoy the well-merited reputation of being the first to introduce some of the finest trees of that remarkable country. To enable him to do this, Mr. J. G. Veitch has possessed advantages which no previous travellers ever had. Arriving in the country after the opening of several ports, and under the most influential patronage, and attached as he was, as botanist, to the consular establishment at Yeddo, he occupied a position of which he

Shoot and Young Cone of *Sciadopitys verticillata*, natural size. Drawn by Mr. Fitch from specimens sent home by Mr. J. G. Veitch.

was not slow to take every advantage, and as such he had the privilege to penetrate into the country and make excursions which were denied to all other Europeans except to such as were attached to the establishment. It was thus that he was permitted to join in the pilgrimage to Mount Fusi Yama, a privilege in which no European ever before participated.

Kämpfer and Thunberg were content to look upon it at a distance, and to listen with unsatiated curiosity to the legends which are associated with it, and the rapturous terms in which the natives describe it, which are to the effect, as Kämpfer says, that "poets cannot find words, nor painters skill and colours, sufficient to represent this mountain as they think it deserves." Mr. Veitch, however, ascended to its summit, and, profiting by the opportunity, possessed himself of the botanical riches by which he was surrounded in his route.

Among the discoveries made by Mr. J. G. Veitch, the subject we this day illustrate is one of peculiar interest, and is described by him as "*the finest tree in Japan*." It is *Seiadopitys verticillata*, the Parasol Fir of Japan, and is found as far north as Hakodadi, where the thermometer is often below zero; and there cannot, therefore, be a doubt, but that it will prove perfectly hardy, and capable of withstanding the frosts of our severest winters.

The tree attains the height of 150 feet to 180 feet, and is of an erect pyramidal growth with straight, wide-spreading branches, and thickly-set shoots, retaining its foliage to the ground. The leaves are from 2 inches to 4 inches long, and two lines broad, arranged in whorls of thirty or forty, and of a yellowish-green colour, forming on the extremity of the shoots a parasol of leaves 5 inches or 6 inches in diameter. As these parasols remain from three to four years green, there are always from three to four of them at intervals of an annual

shoot on each branch. From the figures so skilfully drawn by our artist, Mr. Fitch, an opinion will be formed of the size and shape of the cones. The flowers of the tree are dioecious, and appear at the beginning of summer, and the females preserve

their cones till the spring following. These, from the specimens sent home, appear to be produced in clusters, and are not unlike those of *Pinus cembra*. Each scale bears on its superior surface seven seeds, which are of an elliptical shape, and are bordered with a membranous wing.

The Parasol Fir is one of the most beautiful Conifers of Japan, and one of the most rare. It is found extensively in the eastern parts of Nippon, on Mount Kôjisan, in the province of Kii. Mr. J. G. Veitch discovered it after his return from Fusi Yama, in the middle of September, 1860, growing in the neighbourhood of Kanagawa, and the seeds arrived in England on the 27th of November following; this being the first introduction of *Seiadopitys verticillata* into this country.

The tree is called by the Japanese *Kôja maki*, and by the Chinese *Kin sjo*, the latter signifying Golden Pine, from the yellowish-green colour of the leaves. The scientific name of the genus was established by Zuccarini, and is de-

rived from the Greek *skios*, a parasol, and *plus* a Fir tree, the leaves being arranged, as we have already stated, in the form of a parasol on the extremities of the shoots. It is our intention to continue notices of these new introductions.—H.

Cones of *Seiadopitys verticillata*, natural size, drawn by Mr. Fitch, from specimens sent home by Mr. J. G. Veitch.

HERTFORD NURSERIES.

MR. E. P. FRANCIS.

THE cross lines by rail taking up so much time, I stayed at Hertford for the night after leaving Sawbridgeworth, and called on our old friend Mr. Francis in the morning. The first appearance between these two famed nurseries presented plenty of the ideas of contrast and comparison. At Sawbridgeworth new glass houses have been so much in vogue, that a person who knew the place ten years ago would scarcely recognise it now. At Hertford, with the exception of a small vinery, the houses are much the same as they were twenty years ago. At Sawbridgeworth you are struck with great ranges of glass, the wood scarcely seen owing to the large squares of glass used, almost all being

20 inches by 12 inches. At Hertford you meet with what, ere long, will only be mementos of the past—houses formed with sliding sashes, heavy rafters, and the sash-bars thick between them, and supplied with glass of all sizes, and triangular and other shapes, reminding one of times when glass was a serious consideration. And yet a very slight survey was sufficient to show, that good workmanlike results are much more dependant on the genius of the workman than on the finest tools or the most perfect machinery. Without, perhaps, clearly intending it from the first, the bent of circumstances is leading Mr. Francis gradually to act more and more on the division-of-labour principle;

and this, no doubt, has rendered him more careless of building glass houses, and more bent on extending his grounds from a few acres, which I recollect them to have been, to a fair-sized farm which they are now threatening to become.

I found one house next the street, or road, well supplied with forced bulbs, Chinese Primulas in fine varieties and looking very gay and nice, independently of the little bits of glass in the front sashes. Another lean-to house was appropriated to Camellias opening their buds. Another was filled with Azaleas in fine specimen plants—from those in large pots and huge size, to beautiful compact little specimens in eight-inch pots or so, and splendidly set with buds, the points being all hard, which is more than can be said of Azaleas generally this season.

What surprised me most of all were the fine Rose plants in pots that have been so much admired at metropolitan exhibitions, just beginning to break their buds on the 8th of February, *squeezed thickly together in one of those dark lean-to houses*. More room would, ere long, have to be found for them by removing some to another similar-sized house; but at the thinnest, the plants even when in bloom must stand thickly together, and work must be done in these old-fashioned, but clean, tidy houses heated with old flues—the half of which work, if wanted from some of our modern gardeners with all the appliances of fine light houses, and all the improvements in heating by hot water, would lead them to indulge in no end of complaints and grumbling. It is all very well in large establishments to have a place for everything and everything in its place, and allow no other thing to be in that place; but that would not suit the purpose of the generality of our readers, who wish for great variety even in their small houses. I can well believe them, therefore, when they tell me, that when visiting gardens they pick up more useful hints from small well-kept ones than they generally do from princely establishments. Not but things may be managed as economically in the latter as the former, or even more so; but there is not, in general, the same conflict going on with little difficulties and the want of room, and, therefore, the same amount of sympathetic interest is not felt. A gentleman once summed up the qualifications he wanted in a gardener by saying, "In a word he must have given up, or be willing to discard, the word '*impossible*.' I hear it so often that I am heartily sick of it. I should even be satisfied with '*I'll try*;' but the prophets of impossibility have such a knack in proving their prophecies correct and true, that I will have none of them." I trust these fine Roses in pots will have as many admirers in the coming season as they have had in years past; but we must also see the little lean-to houses from which they come, would we be learners in the "*impossible*" philosophy. After all it is only the exemplification of the old proverb, "A good workman never stands still for the want of a tool;" in other words, men of great practical intelligence, instead of being controlled by circumstances, make even these circumstances, however awkward and obstinate, bend in subservience to their will.

On my last day visit to this nursery years ago, there was a fine collection of bedding plants, which was not such a common affair at that time as it is now. This is still made a prominent feature, though, perhaps, not to the same extent. Some small houses were filled with Calceolarias with names unknown to me. Verbenas in small pots just potted off, and which I should have liked to have had the pleasure of topping several times before May; and lots of fine little plants in small pots of Scarlet Geraniums, which would get large 60's or small 48's as soon as room could be made. Amongst other things I noticed some fine large store-pots of Petunias needing potting, and more particularly the Shrubland Rose—in my opinion as yet unsurpassed by any so-called improvements upon it. A number of our readers are slow to understand that a plant at 6d. or 1s. may be much cheaper than one at 3d. The Geraniums, &c., after such potting and attention must be fine plants before May; but I presume it will be of little use going or sending to Hertford for any, as one of the men told me that their bedding stuff was soon all cleared out, and that they could easily sell ten times as much if they had it.

A few years ago I drove through Hertford and the suburbs on a fine autumn day, and could not help noticing the pretty effect produced by bedding plants, alike on the lawn of the villa and the garden of the cottage. Some cottage homes were rendered very picturesque by having even the roofs covered with Vines, or with a great variety of the Vegetable Marrow and Gourd family, used young as a vegetable, and when full grown for pies and puddings; and then how gay the windows and the borders

looked with flowers! Instinctively we feel in such circumstances that there is a kinship in the love of the beautiful. Many of these industrious residents of the cottage homes of old England, raised above poverty on the one hand, and having no desire to enter the costly regions of an assumed unsatisfactory gentility on the other, would freely purchase for the gratification of the eye a few dozen of showy plants, could they get them in their own neighbourhood free from all uncertainty as to carriage and package charges, and, what is more important, the plants fresh and uninjured from such packing and journey. If what is now grown does pay—and we presume it does, or the practice would not have been continued so many years—and if the supply falls so short of the demand, I trust that our friend will increase his means and room for ministering to this gratification, so that his neighbours may have flower-beds in their little gardens, or, at least, flower-boxes in their windows, as well as China and Tea Roses against the walls of their houses.

It is not alone at Hertford, in this district, that the demand exceeds the supply. However, no man is to be blamed for loving that bridge the best that enables him with most comfort and safety to cross the stream. The open-air nursery has long been the principal thing with Mr. Francis. There is more variety than at Sawbridgeworth, but there is something in common, as respects the division-of-labour principle; but whilst Sawbridgeworth may be described as a manufactory of fruit trees and Roses, Hertford Nurseries may be chiefly considered a manufactory of Roses and fruit trees.

Fortunately a great many Roses, and trees, and shrubs had been sold in the autumn, and the very moving would save them greatly from the frost. The severe Christmas weather, however, had left its traces everywhere. The home ground lying low and close to a sluggish stream, I was surprised to find Peaches and Apricots comparatively little injured. A fine plot of Aucuba japonica was perfectly black, and the wood seemed killed to its base. Alaternuses, Phillyreas, and even evergreen Oaks were greatly injured, and most of them rendered unsaleable for the season. Cupressus funebris seemed killed outright, C. Lambertiana ditto, and many others more or less injured. A fine quarter of common Laurels seemed killed to the bottom. Mr. Francis sent out a great many the preceding year, fortunately; and these, from what I have seen of them, are all right, partly owing to the moving. Araucarias in many cases had their points burned red and drooping, whilst others were green; showing that in similar circumstances different trees of the same kind have different degrees of hardiness, either from the seeds being brought from different positions as to heat and cold, or from other causes as yet unexplained; and what grieved me more, perhaps, was a quarter of nice plants of Pinus insignis, either killed outright, or so injured as to spoil the sale for a year or two.

Though a great many standard Roses had stood the test, yet many of those budded last season had the bud destroyed; and great quantities of the tenderest were either killed or so injured as to be unfit to be sent out this season. The Teas and tender Roses budded low on the Manetti stock were much injured, as far as could be judged on the 8th of February; but Bourbons, Perpetuals, and Hybrids seemed comparatively safe and sound, partly owing to being budded so low, and also to a light skiff of snow on the ground. Had such a frost been expected, and a little earth put round the buds, most likely even the tenderest Teas would have escaped uninjured.

The distinctive feature of the place, however, is the prominence given to the Manetti stock, which Mr. Francis seems to have so thoroughly mastered, that, though many complaints have come in my way of Roses on this stock, I am not aware of a single complaint even from every variety of soil in the case of Roses supplied by him. He candidly states that it will never do for standards, as the stock will ultimately get so hard as to starve or throw out the bud; neither has he any faith in grafting on that stock for similar and other reasons; nor yet does he consider budding on dwarf stocks of any use, unless the bud is inserted close to the ground, so as to be partly covered or wholly covered when transplanted. Then the shoots of the favourite Rose will grow with a vigour unknown when placed on any other stock, or any Roses on their own roots. A regular systematic course is followed from the making of the cutting to its being budded and after-treatment. In a house combining the properties of a greenhouse and working-shed, nice and comfortable from a flue, a number of men before breakfast were dressing the cuttings of the previous year, removing all the roots and shoots up their stems, leaving only the lower ring of roots at the

bottom, and some buds at the top, to sustain free growth; and after breakfast these nice cleaned plants would be planted again in rows, and be budded as soon as the buds were ripe. Some fifty thousand of these cuttings were planted last season, and all would go through this treatment. I saw men going away after breakfast, carrying great buidles of fresh cuttings all of one length—about a foot, as near as I could guess from a distance—as part of the eighty thousand, or one hundred thousand that were intended to be planted this season. The foreman, who has been in the place something like a lifetime, might well say that though fifty thousand even was soon said, it was no joke to get even that number through one's hands. There are other minutiae on which, no doubt, some of the success of the system depends. To a benevolent man there is no slight recommendation in the fact, that in carrying it out the workmen need hardly ever in the cold months of the year have a wet coat, or be frosted out when food and fuel are most needed. A great part of the work in dressing the rooted cuttings and making fresh ones is done in inclement weather in winter, and favourable time selected for planting them.

The shrubs, as a whole, escaped the frost well, with the exception of those indicated; and the fruit trees, standards and dwarfs, were young and healthy. On the whole, the two hours spent only whetted my desire, if possible, to have a peep at these nurseries when all was a-growing and a-blowing.—R. FISH.

BRITISH FRUITS & POMOLOGICAL CLEANINGS.

BEURRÉ LEFÈVRE.

SYNONYME—*Beurré de Mortefontaine*.

THIS is not at all a new Pear, for it has been in cultivation for several years; but it is one of which very little is known, although it is to be found in almost all respectable nurseries. When we consider the immense number of varieties of Pears that are now cultivated, it is not to be wondered at that some which are of first-rate quality should escape notice in large collections, until, by some fortunate circumstance, attention is called to them. Such is the case with *Beurré Lefèvre*, of which I first took especial notice in 1859. In that year I found it to be one of the most delicious and refreshing-juiced Pears—not with melting or buttery flesh, but with that crisp, tender, water-ice consistency, which, though of a different character from the other, is in its way equally estimable.

Skin greenish-yellow on the shaded side, and very much covered with a crust of brown-olive russet. On the side next the sun the whole surface has a brownish-orange tinge showing through the thin russet coating, very much covered with large grey specks; in some parts there are broken streaks of red.

Eye very large and open, with long, spreading leaf-like segments, set in a pretty deep, uneven basin.

Stalk an inch long, fleshy at the base, and obliquely set on the surface of the fruit.

Flesh white, rather coarse-grained, half-melting, crisp, short, and very juicy; rather gritty at the core.

Juice very sweet and richly flavoured; with a strong and peculiar aroma, which is very agreeable.

A delicious Pear, ripe in the middle of October. It was raised by Messrs. Lefèvre, nurserymen, of Mortefontaine, near Paris, from whom I received it eighteen years ago.—H.

PEACHES ON A WALL AT CHRISTMAS, December 18th, 1860.—

On going into my neighbour's garden to-day I saw what was to me a rare sight—a Peach tree trained to his wall covered with fine fruit of a rich golden yellow, with their sunny sides of a deep crimson, and its leaves perfectly green. Some garden-lights were placed against the wall; they had been there only a week. The fruit were soft and ripe, but perfectly flavourless. The variety is American, and called *Poole's Late Yellow*. In 1858 its fruit ripened in the middle of November, and were then of excellent flavour. The peculiarity of this late Peach, and also of the *Salway*, is its retaining its leaves fresh and green long after other kinds of Peaches have shed theirs, and thus bringing to maturity its late crop of fruit.—T. R.

THE EARLY MIRABELLE PLUM.—This very pretty little Plum is nearly as early as the *Jaune Hâtive*, ripening about the third week in July. It is round, of a bright golden yellow, spotted with red; parts freely from its very small stone, and is rich, sugary, and excellent. It is more dwarf and slender in its habit than the *Mirabelle Petite*, and will, doubtless, form a very pretty bush for the orchard-house, in which it will probably ripen in July, though the berries were not larger than peas.

INGRAM'S NEW GRAPE.—During a call we recently made at the nursery of Mr. Standish, of Bagshot, we saw a Vine-pit planted entirely with this new variety, where it is now being forced; and we were pleased to see that it gives great promise of being not only a very prolific and early sort, but that some of the bunches are already upwards of a foot in length and well shouldered.

ENGLISH RAISINS.—Some time towards the end of last September I received some Grapes packed in bran from a correspondent, who wished me to give him their names. There were two bunches—one of the *White Frontignan*, the other *Royal Muscadine*. A few Grapes were taken from each bunch to ascertain their names; the rest were replaced in the box and covered with the bran, which had apparently been sifted, as it was very coarse and free from particles of meal. The box was closed, and placed on a shelf in my library near the chimney. A good fire was kept in the room all the autumn and winter up to the present time, the box quite forgotten. To-day (March 28th), it was by chance opened, and the Grapes found to be perfectly sound, but like *green Raisins* and most delicious; the *Frontignan* flavour quite apparent in one sort, and the *Muscadine* flavour in the other. This is really a pleasant discovery; for how agreeable it will be to have our Grapes, or rather these home-grown Raisins, at Christmas, without the trouble of preserving them on the Vines, which, as we all know, requires much care and attention. It seems to me, that in a good Grape season, when Grapes on our walls are plentiful, we have nothing to do but to dry a quantity of bran, sift it thoroughly, and then place our Grapes in it in closed boxes, placing them in a dry warm cupboard or on a shelf near the chimney. Grapes from our vineries may, of course, be preserved in the same manner; but such large juicy sorts as the *Black Hamburgh* will, probably, require looking to if the experiment is tried with them. At any rate, the experiment is simple and inexpensive. In proposing bunches of Grapes to be preserved in bran, it occurs to me that the berries should be thinned, so as not to touch each other; the bran will then enclose each berry, and the gradual drying will preserve them effectually.—R.

A NEW VEGETABLE.—There has lately been exhibited at several meetings of the Royal Horticultural Society a new vegetable which promises to become a permanent institution

The fruit is inodorous, large, and somewhat oval.

among kitchen-garden crops. It is a Cabbage in the form of Brussels Sprouts. The stem is about a foot high, bearing on its summit a good-size-hearted Cabbage of the ordinary character; but the stem is covered with small Cabbages about the size of a small dessert Apple, and these when cooked form an excellent dish, partaking of the flavour of a nice summer Cabbage, and without the strong Savoy flavour which distinguishes the Brussels Sprouts. The merit of producing this variety is due to Mr. Wm. Melville, Dalmeny Park Gardens, near Edinburgh, and a very good name by which to distinguish it would be to call it *Dalmeny Sprouts*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, the beds should be spring-dressed immediately, if not yet done. *Beans*, earth up the advancing crops when the ground is moist. *Beet*, sow Green and White, for the stalks. *Borecole*, sow the main crop. *Broccoli*, sow a small quantity of all the principal sorts. *Brussels Sprouts*, sow for the main crop. *Cabbage*, if any of the autumn-planted ones are running to seed pull them up, and replace them with some from the autumn-sown bed. *Cauliflowers*, get the plants raised under glass hardened off, and pay every attention to those under hand-glasses to get them in as early as possible; for the destruction of the Broccoli will render them most valuable this season. *Celery*, sow seed for the late crops; those pricked out in frames to have plenty of air, to prevent elongation, and to be well supplied with water, in fine, dry weather. *Cucumbers*, earth up as they require it. Keep up a brisk heat in the bed, but beware of overheating it. As long as it is necessary to keep strong linings, a temperature-stick should be kept under each hill of plants. *Lettuce*, a few of the earliest may be tied up on a dry day; tie them as near the top as possible, to prevent the wet getting to the heart. *Radishes*, thin out advancing crops, and sow the Turnip-rooted kinds. *Sea-kale*, sow seed. If a new plantation is to be made it should be done without delay. The destruction of weeds and insects is now a matter of importance. All root weeds to be dug up; the Box-edgings to be clipped, if not done in the autumn; and the walks kept clean.

FLOWER GARDEN.

Continue to prune Roses. Roll walks, and fill up blanks in the flower-borders and artificial rockwork. Sow Auricula, Polyanthus, Ranunculus, and Pansy seed. Pot Carnations and Picotees in their blooming-pots, placing oyster-shells on the surface of the soil to prevent too rapid evaporation. Plant out Hollyhocks: these have a splendid effect when arranged with the tallest behind, and where contrast of colour has been carefully studied. Look over the beds planted with bulbs, and where necessary stir the surface soil, so as to give it a clean, neat, fresh appearance. If any alterations and planting still remain unfinished it should be completed without delay, as planting after this time is apt to suffer very severely in dry weather. Stir the surface soil of the seedling Pansies in beds, and give them a dressing of manure. Turn walks, and fresh coat with gravel. Plant Box-edgings. Sow hardy annuals of all sorts. Prune and tie all evergreen climbers, and roll and mow the lawn.

FRUIT GARDEN.

Disbud Peach and Apricot trees. It is best to go over the trees occasionally, removing a small portion each time.

STOVE.

Attend to the culture of each particular plant, and go on propagating, potting, and shifting. Encourage growth by syringing with clear water all over the leaves and every part of the house, filling it with vapour. Admit air on all favourable opportunities, but close up early to secure solar heat. When the blossoms of *Euphorbia jacquiniæiflora* fade, the plant to be cut down, and kept comparatively dry until it breaks; then to be repotted and encouraged to grow. If an increase of stock is required, now is the time to set about it. Young plants of *Allamanda*, *Clerodendrons*, *Torenia*s, and many other things, if encouraged with a brisk bottom heat and other favourable circumstances, will form nice-sized specimens in a few months.

GREENHOUSE AND CONSERVATORY.

Look very carefully to the watering at this critical season. Recently-potted plants to be kept close and syringed frequently, so as to maintain a rather humid atmosphere, and

apply water very sparingly until the growth of the plant indicates that it has taken to the fresh soil. Get a portion of the *Epacris* into a gentle heat as soon as they have sufficiently recruited their energies after blooming. Proceed as vigorously as possible with the repotting of such of the hardwooded plants as require it, so as to afford them every chance to make a vigorous growth. See that *Pelargoniums*, *Cinerarias*, and *Calceolarias* are allowed plenty of space, and that they are sufficiently supplied with water and kept perfectly clear of insects.

FORCING-PIT.

This department will soon be unnecessary, so far as the forcing of flowers is concerned, but it will become useful to give encouragement to some of the free-growing stove plants, which now require plenty of room. Some of the plants may also be removed from the dung-frames to this pit to make room for Balsams, Cockscumbs, Amaranths, and such other plants that are intended for the summer and autumn decoration of the greenhouse and conservatory.

FITS AND FRAMES.

Sow German and Ten-weeks Stocks in a cold frame, or in one that will soon cool down, and some German Asters on a slight heat. *Verbenas*, *Salvias*, &c. may still be propagated for the flower-beds and borders. The bedding plants to have all the air that can be safely given to gradually harden them off for turning out.

W. KEANE.

DOINGS OF THE LAST WEEK.

The work was chiefly of a routine character—digging, trenching, and pulverising the soil—when the weather would permit. Planted out more Ash-leaved and round Early Frame Potatoes. Finished planting out Peas and Broad Beans from boxes, protecting both with a few twigs of laurels, and staking the former as the work proceeded to prevent the ground being trampled on. Sowed various *Lettuce* seeds, as Carter's Giant Cos, Paris Cos, Blackseeded Brown Cos, and Neapolitan, and Hardy Hammer-smith Cabbage, only a few seeds of each, as the great secret of a thorough good supply is the sowing often. Sowed also Cauliflower, and for the main first crop of winter Greens, as Scotch Cabbaging Kale, Brussels Sprouts, Savoy, Broccoli, of which, with the exception of Snow's Early White, we grow little, the crops being so uncertain of late; Cottagers' Kale, Melville's Garnishing, which we suspect to be much the same as Variegated Kale, which either in its white or red appearance looks well on the table; also, a few Coleworts for early supply. These are sown quite early enough; but a second sowing will be made in a few weeks. Some calendars seem written more for the south of France than England as a whole. Pricked out Cabbages, Cauliflower, and Lettuces in an earth-pit, that were sown broadcast in a Potato-bed, to be protected with a few branches. Watered Potatoes in pots, now fit for use; also, Potatoes in beds, and Kidney Beans in pits, giving the latter manure water to prevent them exhausting themselves in bearing. Sowed more in boxes for transplanting. Watered *Cucumbers* also with warm water. The small plants in the frame heated by leaves and dung, though a fortnight behind those in the hot-water pit when planted, are now at least a week before them, if not a fortnight: fruit swelling and setting nicely. Both are healthy and luxuriant, never having shown a fly, &c., and I hope will not vex us as they did last year; for with every attention I could barely get enough to meet the demand, which I felt all the more, as usually even from a small space we used to have more than abundance. I mention the above fact about the Cucumbers to show that dung and leaves are not to be despised; and then what valuable heaps they become afterwards! I fully believe that a good supply secured, these beds will produce as fine crops as any hot-water apparatus, when growing is not commenced extra early. When Melons are grown in pots, we prefer hot water, and the plants to be on a trellis—the best place of all for first-rate fruit as to quality.

Nailed, when the weather was fine, and finishing pruning. Watered Vines in houses, also Peaches ditto. Made up a bed for three-light box, of the litter that came from Celery-beds and a few hot leaves, now in nice condition, for Melons. Potted off a few young Vines from buds just beginning to root, placing them singly in small pots. Prefer placing each bud with an inch of wood on each side in a small pot at once, but had no small pots to spare at the time. Planted out three lights more Cucumbers, two strong plants to a light.

Sowed more *Tender* and *Half-hardy Annuals*, and, among the latter, Ten-week Stocks, Zinnias, and China and German Asters, placing them in a mild heat. They are quite early enough, but they must stand a little rough treatment after they are fairly up. The 1st of April is generally a very fair time for sowing, if planting out does not take place until the 20th or the end of May. Zinnias being scarcely safe until the beginning of June, and before planting out, all should be pricked out from the seed-pan, and have nice roots before moving. In sowing, we fill either pots or boxes half full with rough material, generally riddings from beneath the potting-bench, then 2 inches of sandy loam, and then a little fine sandy loam, on which the seeds are sown, and some finer still with a little peat earth and silver sand for covering. The covering depends on the size of the seeds. For large seeds, such as the finer Lupins, from one-eighth to one-quarter of an inch. For such seeds as Cockscombs and the *Perilla nankinensis*, about one-twentieth of an inch. For such very small seeds as *Calceolaria*, *Lobelia speciosa*, and *Portulaca*s, the slightest sprinkling, and that generally of dry silver sand. For all small seeds the surface is first made smooth with a board, and the same smoothing is resorted to after the slight covering. Our rule is never to cover deeper than the thickness of the seeds. Deep covering gives many an honest seedsman a bad name. Another matter of importance is, for all such seeds placed in pots, &c., especially small seeds, to keep them shaded before the seedlings begin to appear. Those we sowed the other week and so treated are beginning to show, such as *Brachycome*, *Perilla*, &c., and these must have light and comparative coolness ere long to keep them from damping. The shading is accomplished by an old newspaper, or anything of that kind, being placed over the pots. We generally leave them about a week under the paper before watering, as the seeds imbibe moisture from the soil; and then when watering, instead of using a rose of any kind, I prefer flooding all the surface with water, by pouring the water against the sides of the pot, in a crock, or oyster-shell held in the hand. I do not give any theory, but I know in practice, that a pot thick with tiny seedlings will neither damp nor shank when so flooded, or sailed, all over in anything the same proportion as they will do when watered from a rose, however fine. The great remedies, however, against loss from these causes, is pricking out either singly or in patches, and giving more air.

Continued planting out *Calceolaria*s in earth-pits covered by calico, and commenced doing so with *Scarlet Geranium*s, merely forking the bed which seems rather wet, and making little trenches for the plants 6 inches apart, and placing sandy leaf mould immediately round the roots. These at planting time generally lift well. *Pelargoniums*, *Camellias*, *Azaleas*, &c., wanted more water, owing to a few sunny days. After a few dull days the sun, when powerful, tries the soft succulent leaves of *Cineraria*s and things of that kind; and when not dry, anything like flagging will be guarded against best by syringing the shelves and stages, keeping the plants on damp moss, and even sprinkling the underside of the leaves.—R. F.

TO ADVERTISERS.

We have to apologise to many of our friends whose advertisements are unavoidably excluded from this day's publication. We request that those who are desirous of taking advantage of the publicity which our pages afford, will send their advertisements as early in the week as possible, that the necessary arrangements may be made for their insertion.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.

NAMES OF BRITISH WILD FLOWERS (S. Devon).—No. 1, *Luzula campestris*, or Field Wood-Rush. No. 2, *Mercenialis perennis*, or Dog's Mercury, a female plant. You will see by an advertisement that we purpose publishing on the 1st of May the first Number of the cheapest illustrated work on British Wild Flowers ever offered to the public. We can safely say that the drawings are faithful portraits and beautifully coloured. We shall be particularly obliged by any one sending us good fresh specimens of rare British plants.

SEEDLING *CINERARIA* (J. Loose).—A good, stont-petaled flower, but there are many like it. It would not pay to send out.

RISE IN HOT-WATER PIPES (A Very Old Subscriber).—It will be no detriment whatever the rise of 18 inches in a length of 60 feet of the flow-pipe, and the same amount of fall in the return-pipe. Of course you will have the flow-pipe proceed from near the top of the boiler, and the return-pipe join it near the bottom. One four-inch pipe at the back, and one at the front, will be ample for early forcing of Cucumbers.

FOAKING BORDERS (J. Lady).—This is far better than digging them with a spade, as it injures less the roots of shrubs. Indeed, the fork has nearly superseded that old emblem of the gardener's occupation—the spade. A four-pronged fork for stiff soils, and a five-pronged fork for sandy soils, work them quite as thoroughly as the spade, and with the expenditure of much less strength from the workman.

QUERIES (Nottinghamensis).—It would occupy space uselessly to put in queries which are sufficiently indicated by their answers, or such queries as are only interesting to the inquirer. All others we do insert.

PLANTING A CIRCULAR ROSERY (M. M. P.).—We cannot relax from our rule, so many times repeated by us—we cannot plant strange places for any one. Our correspondents must tell us how they intend to plant, naming the plants, and specifying the spots on a plan where they propose to put them—we are then willing and ready to point out where the plan is wrong.

GROWING *ACHIMENES* (The Doctor).—Pans are better than cinoline-pots to grow *Achimenes* in when one has abundance of plants of them; and for a very small quantity of any scarce kind No. 48-pots are the best to start them in, then to give them a shift if they need it.

NAME OF *HYACINTH* (Peckham Subscriber).—It is almost impossible to tell from a single pip, but it is probably *Comte de la Costa* or *Regina Victoria*.

PHILEAS BUXIFOLIA—*LILIU GIGANTEUM* (An Old Subscriber).—The *Phileas* ought to be hardy at Colchester; but it is a good pot plant, and might be with the Chinese *Azaleas* till it blooms or is of a flowering age. It requires peat in the soil and much moisture. The offsets on the gigantic Lily do it no harm, and are no indications of its going to flower. The first notice of flowering is an upheaving in the centre, like that of the scarlet *Lobelia*s or *Campanula pyramidalis*, and will go on exactly in that manner. Some of ours have such an appearance already in the centre of the pots.

CYCLAMENS IN BOXES (H. B.).—Different varieties of *Cyclamen persicum* were meant only for one box, and if Mr. Beaton advised otherwise he made a mistake.

DWARF IVY BUSHES (C. P.).—You were quite explicit at first; we only imagined no one was so extravagant in these things as we have been, for we have been wishing for many years to possess an Ivy bush—upright as white currant bushes, and nearly of the same shape and size; and it is a comfort to know at last that the idea is not unique. We have struck cuttings of the arborescent Ivy, or the flowering shoots, which are the same thing, and we had them with their entire leaves on for half a dozen years; but they never got bigger all the while, and the first growth they made, away they went with shoots longer than ever and with lobed leaves. But now that you have struck the flint at the proper moment, there is a way of doing it, and of having quite a forest of round-headed Ivy trees, with trunks and branches, entire leaves, flowers for the bees, of which they are passionately fond, late in the autumn, and berries for all the thrush tribe in winter. Let the Ivy trees be as one row of Mr. Rivers' miniature-orchard, and let the whole row be lifted and transplanted every other year; and if that row does not produce twice as much fruit as its trees, let it be often transplanted till it does. Now is just the time to begin making Ivy trees. Procure some stont flowering branches from a ruin, or from near the bottom of the Ivy half strangling a tree, fix on a part of the branch as near the bottom as you can, to give you the more length of trunk after it is rooted; then, to cause it to root, cut off a ring of two inches in width of the bark, all but about the width of the fourth of an inch, and leave that narrow slip of bark to carry on the circulation; then get some sheets of gutta percha paper, or parchment, and form each of them into the shape in which grocers make their soft sugar parcels—the pointed end tie tightly a little below the ringed part, and let the open part of your paper be 9 inches or 10 inches wide, and deep enough to hold as much good, rich, sandy loam as would fill a No. 24-pot, pack the soil tightly round the ringed part, but not very tight above it, water it well and keep it well watered till next October, when it will be as full of roots as possible; and then cut it off from the old tree, and plant it carefully in a sheltered place, and see it is well staked. A layer of moss on the top of the soil in the gutta percha paper, and a little of the moss all round the wound in the bark will hasten the process of rooting. If the stem of Ivy is as thick as some we know, one would need half a bushel of mould, and two years to root it properly.

PROPAGATING VARIEGATED *ARABIS* (Idem).—The variegated *Arabis* partakes of a wide-spread principle among plants just coming into bloom, as it naturally does early in the spring. Plants under that principle do not readily root from cuttings freely on the eve of blooming, so that it is necessary to excite them to grow out of "flowering wood" ere the cuttings are made. In May it roots out of doors under a hand-glass freely, and so on till September. The old plants may be slipped to pieces in October, and every bit with or without a root grows. In January it should have three weeks' forcing before cuttings are made of it. But it deserves all the care and attention of the whole gardening strength of the British Islands. If it stands the influence of the sea-breeze under exposure, this is the best variegated plant for the whole of the Hebridean archipelago.

CUTTING BACK *WEIGELIA ROSEA* (R.).—Let it bloom, and cut it back afterwards; unless you are willing to cut it now, and sacrifice the flowers for this season, in order to get a more bushy plant well furnished from the bottom, and of a superior shape. This would be preferable.

PRUNING STANDARD ROSES (Idem).—All the very strong Roses are the better to be pruned thus late in the season, because, ere this time, their upper shoots are bounding away in full growth. By cutting off the upper half now, and a little more from the smaller shoots, so much of their pride, or over-strength, is got rid of, and the steady, sober, and self-ripened eyes below will come with less speed and more bloom, and make better wood for next pruning. It is now too late in the spring to remove Standard Roses, but of course they can be removed with a sacrifice until the end of April.

PELARGONIUMS FLOWERING PREMATURELY (*Inquirer*).—You either cut down your Pelargoniums which you need for a June show at least six weeks too soon last summer, or else you have kept them too warm since last October. Now, if you have a memorandum of the week and day on which you cut them, say three weeks of an ordinary summer will be equivalent to six weeks of such weather as we had in the cutting-down season of 1860: therefore, cut them back this season just three weeks later than you did in 1860, if you mean them for the same show. Then turn to the journal of your temperature in the Geranium-house since last September, and see how much the average of each week of temperature inside differs from the weekly average out of doors, for daily averages are of very small practical use. Then, if you have made any monthly memorandum on the looks and progress of the plants, that also will assist you in calculating your work for the future. Then make a monthly mean of your house temperature, and of the natural; also a mean of both temperatures for the four months succeeding October, and you will find the in-door temperature a good deal more than it need have been. This will give you a safe guide for next winter, which, if you follow, will enable you to beat every competitor who works on the hap-hazard plan. Meantime you must not stop such Pelargoniums, you must keep in a very dry place, and as cold as the season, without frost. We have seen many specimen plants put into deep cold frames this last March for next June shows. The cold frame was on purpose for retarding: a row of posts 5 feet out of the ground at back, another in front 3 feet or so, wall plates and rafters, and all the sides of boards made to hinge up and down, so as to cause the plants to be nearly as cold as if they were in the open air, and merely covered with glass. In very hot or sunny days they put mats over the glass. So you see you are not the only one who is out in his reckoning by this winter.

PURPLE ORACH (*Idem* and *J. H.*).—We stated that the Purple Orach is purple, or do you doubt our meaning, or prefer the *rubra* of botany, which may cover every morsel of red purple? It is not red, but is the finest purple, and would be inimitable purple if the leaves were of that satin texture which you see in *Cissus*, and such plants.

PROPAGATING SAXIFRAGA OPPOSITIFOLIA (*Idem*).—The best way to propagate the *Saxifraga oppositifolia* is to divide it into little bits like Lemon Thyme, and to plant the pieces a little deeper than the plant was set.

BOTANICAL TERMS (*A Beginner*).—You will find a copious glossary well illustrated with cuts in Dr. Lindley's *Elements of Botany*. We do not know of a better.

CONVERTING A PIT TO A GREENHOUSE (*T. Wallace*).—As the roof is fixed, you must have means for getting into the pit; and the comfort altogether would be increased if you had a door at the end, and a narrow path—say 15 inches or 18 inches wide—close to the front wall of the pit. Of course you could not then have a stage extending from the new front wall, until passing over the flue; but with that stage over where we conceive your pathway should be, we do not see how you are to get at your plants with a fixed roof. We think, by allowing your flue to remain as it is, and the front wall of the old pit as it is, you will have plenty of heat; only, if your pit is filled above the flue with leaves, dung or tan, you would require to make a few holes in the front wall opposite the flue—say four, a foot or so square, furnished with a sliding board to let heat out into the atmosphere of the pit. If the top of the flue is left exposed, that will not be needed. These little matters secured, we think you may calculate on doing all you propose well.

GAZANIA SPLENDENS (*Idem*).—As far as is known at present, it can only be depended upon to come true from cuttings.

VARIOUS (*A. B.*).—Spring cuttings of bedding plants should have a bottom heat of 80°, and a top heat by day of 66° or 70°, with 10° less at night, and free ventilation. Not knowing how you have treated *Eugenia Ugni*, we cannot tell why it sheds its blossom-buds. It may have been kept too cold, or something may be wrong at the roots. The knife must not be applied to either *Heaths* or *Epacris* until after they have bloomed.

POULTRY, BEE, AND HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

MAY 21st, 22nd, and 23rd. CHESTERFIELD AND SCARSDALE. *Hon. Sec.*, Mr. Thos. P. Wood, jun., Boythorpe House, near Chesterfield. Entries close May 1st.

MAY 22nd and 23rd. BEVERLEY. *Hon. Sec.*, H. Adams. Entries close May 4th.

JUNE 4th, 5th, 6th, and 7th. BATH AND WEST OF ENGLAND. *Steward*, S. Pitman Esq. Entries close May 1st.

JUNE 19th, 20th, and 21st. COALBROOKDALE. *Secs.*, J. B. Chune, and Henry Brocroft, Coalbrookdale.

JUNE 28th. DRIFFIELD. *Sec.*, Mr. R. Davison. Entries close June 22nd.

DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. *Sec.*, M. J. B. Lythall, 14, Temple Street. Entries close November 1st.

N.B.—Secretaries will oblige us by sending early copies of their lists.

DIARRHŒA IN FOWLS.

I HAVE a Spanish cock, which has a frothy discharge at the eyes and a sort of cough upon him. In the midst of his crowing he is generally interrupted by a sneeze or cough. On examining his throat I noticed a yellow-looking substance, which should not be there. My fowls generally are too much relaxed in their bowels, amounting at times to diarrhœa.

I feed on barley and wheat mixed, and barleymeal once a-day. My space is certainly limited, and is in the town confined within four walls; but I have a small grass run—say 20 yards square,

and I give greens and Swedish turnips regularly, and keep my places very clean, and well supplied with fine gravel and water. —A NEW SUBSCRIBER.

[Swedes very frequently cause diarrhœa in fowls, and they are not necessary where fowls have as good a grass run as yours. When any additional green food is required, you will find lettuce better than any other. Cabbage is not so good. You must purge your Spanish cock freely with castor oil, giving a table-spoonful every other day. If the fungus in the throat is small, touch it with caustic. If it is large, bathe it with vinegar and cold water by means of a large soft-topped feather. We would advise you to feed only on meal for a time.]

THE HENWIFE.*

"I THINK," says the authoress in her introduction, "I am entitled, without egregious vanity, to deem my experience worthy of some claim to attention, as, during the last four years, I have gained upwards of three hundred prizes in Scotland and England, and personally superintended the management of forty separate yards, in which have annually been hatched more than one thousand chickens.

"I began to breed poultry for amusement only, then for exhibition, and lastly, was glad to take the trouble to make it pay, and do not like my poultry-yard less because it is not a loss."

Now, this is just the person to write a book upon poultry management; and we assure our readers that we have read the 200 pages forming Mrs. Blair's volume, and that they are unmistakable evidence that she is not only possessed of the requisite knowledge, but that she knows how to impart it explicitly and pleasantly. Houses and yards, food, general treatment, hatching, chicken-rearing, exhibiting, diseases, fattening, description of various breeds, and a balance-sheet, are the various heads under which Mrs. Blair arranges the knowledge she has to impart.

We will give but one extract as an example of the sound information the work contains, and it is on a point too little attended to by poultry rearers:—

"The necessity of damping eggs was not at all understood by the old school, and yet it must be done if success in hatching is desired. Many complaints are made of eggs not hatching though there have been birds in each. This is entirely caused by the neglect of this precaution. Unless moistened, the inner membrane of the egg becomes so hard and dry, that the poor little chick cannot break through, and so perishes miserably. Before dying, its cry, like that of Stern's Stirling, probably has been, 'I can't get out, I can't get out.' Has slavery a more bitter draught than this?

"When a hen steals her nest in a hedge or clump of evergreens, she sits on the damp ground. She goes in search of food early in the day before the dew is off the grass, and returns to her nest with saturated feathers. To this fact is to be attributed the comparatively successful hatching of the eggs of this wild bird. To follow this as closely as possible, put a thick fresh-cut turf in the nest you are about to prepare for the reception of the sitting hen. Sprinkle a little sulphur over this, and spread over it straw in summer, hay in winter. I shall suppose that you have eggs ready for sitting. They should be thirteen in number, or at most fifteen, if set during warm weather. In winter, nine eggs are sufficient for the very largest hen.

"Before hatching your (it may be) valuable eggs, be certain that the hen is really broody. You may give her one or two worthless eggs as a trial; or, if you are anxious not to lose time, divide your sitting between two or more hens, and if one proves truant at the end of a few days, give all to another.

"By sitting several hens at the same time, you have the great advantage of being able to put all the chickens, as soon as they are hatched, under one, and of adding new comers to her flock. Eggs sometimes hatch irregularly, and unless some such system were established, the earliest-hatched chickens would die of starvation before the whole were brought out.

"I strongly deprecate the custom of removing chickens from the nest, and keeping them in baskets before the fire. There is no warmth so suited for them as that of the hen's body.

"After removing the empty shells from the nest, leave the little creatures with their mother undisturbed for twelve hours. When that time has elapsed, you may offer them food and water.

* *The Henwife*, her own Experience in her own Poultry-yard. By Mrs. Fergusson Blair. Edinburgh: T. C. Jack. London: Hamilton, Adams, and Co., and Office of "Journal of Horticulture," &c., 162, Fleet-street.

"If the egg has been chipped for some hours, and the chick does not make its appearance, a slight assistance may be given by enlarging the fracture with scissors, cutting up towards the large end of the egg—never down, or the loss of blood may prove fatal. When the chicken at last makes its way out, do not interfere with it, or attempt to feed it. Animal heat alone can restore it. If it survives the night, it may be considered safe. Weakness has caused the delay, and this has, probably, arisen from insufficient warmth."

The balance-sheet shows a profit of £24 7s. in the twelve months between February, 1860, and February, 1861; but we do not observe any allowance made for the cost of exhibiting. Does Mrs. Blair find that the prizes gained cover that cost? If not, the loss should be on the debit side; for if she had not acquired a name by exhibiting, she would not have sold poultry by auction for £148 15s. 6d., a sum appearing on the credit side.

The woodcuts are excellent, and the drawing of the coloured illustrations is for the most part good, except of that terrible exaggeration the Cochinchina hen; but let no one accept the colouring as correct.

CANARIES' FEET DISEASED.

MY Canaries have been affected in the course of February and this month with an epidemic inflammation in the feet and legs. Can you or any of your correspondents give me any information on the following points? 1, Whether the disease is known? 2, If known, what has been found to be the most safe and effectual treatment? 3, If not known, what is the probable cause in this instance? 4, What would probably be the best treatment?

The symptoms are at the commencement restlessness, and ruffling, sitting on one leg, &c., reddening of the whole limb, and swelling, but chiefly at the joints, soon perceptibly follows; and then the usual moping till amendment begins. Hitherto, no bird has died, but one or two are now sickening, and the cases seem likely to be severe. The food of the birds has been canary, rape, and a small proportion of hempseed, with groundsel till the affection began. After that, egg instead of groundsel, and a little saffron in the water. The birds were accustomed to take their bath in their cage, and it was thought that a chill was given by the damp sand adhering to their feet. Since the first appearance of the disease they have taken their bath outside their cage, as they have a daily flight about the room; but still the birds sicken.—R. S. V.

P.S.—I noticed a very large wasp here on the 5th inst. (March). Is not this unusually early?—R. S. V.

[I only know of two causes of diseased feet—one arises from dirt, and may be cured by the bath and cleanliness; and the other is caused by wool or the fine threads of silk or such substances becoming entangled about their feet and cutting down to the bone, where they are not easily seen or removed. These threads must be picked out, and the feet anointed with oil, and they will soon heal.—B. P. B.]

BEEES NOT WORKING—BEEES PLUNDERING THEIR NEIGHBOURS.

AN *Old Subscriber* is very anxious about a hive of bees in a straw hive. It is strong, full of bees, and well fed since September. All the winter it was kept with another hive on a wooden bee-stand, exposed to the east, but not sheltered in front. Both hives were working well but began to fight, and the straw hive was moved a few feet from the stand containing the other hive, and since the hive was moved the bees have not come out to work. They are alive but seem lazy. Could the queen have died? Do bees generally become quarrelsome when together?

[Endeavour to rouse your sluggish bees into activity by giving food on five days. Use the bottle as recommended by Mr. Woodbury, in page 42 of our last volume, if there is an aperture in the top of the hive. Should there be no aperture, or the bees refuse to appropriate the proffered food, inject a little with a syringe into the hive itself, through a hole formed by thrusting the pointed end of a thick wire between the straw bands near the top. If this fails to set the bees to work, and little or no pollen is collected, we should fear the queen is dead, a misfortune for which we know of no remedy at this season. A bee-house

9 feet long would contain three colonies without much danger from their close proximity; but all should be ranged on one shelf. Bees are less apt to quarrel when the stocks are at a distance from each other, but want of space generally prevents their being widely separated. The strong are always apt to prey upon the weak in an unpropitious season like the present. The entrance of the hive that was attacked should have been contracted as soon as fighting commenced, so as to admit the passage of only one bee at a time; and if this failed to put an end to the conflict, the bees should have been removed to a distance of not less than a mile and a half. As soon as fine weather had set both colonies vigorously to work, the transported hive might be restored to its place without risk of a renewal of the disturbance.]

BEE-HIVES AND THEIR APPURTENANCES.

ANY one commencing bee-keeping must be struck at the great contrariety that exists between writers on this subject, both as regards the material and form of hives and their system of management.

After perusing one author, and resolving to adopt the system so strenuously advocated, the novice is sadly perplexed, on taking up perhaps the very next work that may chance to fall in his way, to find that system controverted, and its opposite as strongly recommended; and after wading through, it may be, the greater part of the bee literature of our country, is landed in a perfect maze of bewilderment. Arriving at this stage, it must act as a soothing opiate to his perturbed feelings to open "Miner's American Bee-keeper's Manual," and there find, condemned *in toto*, the whole authors of the old world from the illustrious Huber downwards; the hives of his own fellow countrymen having a scant justice meted out to them, being described with such Yankeeisms as "take ins," "humbugs," &c., and following his reasoning that the bee remains the same through every age and country: consequently "every bee-hive in the United States should be of a certain size and shape," that after many years of close application he has made the grand discovery which is given forth as "Miner's Patent Equilateral Hive," so far as his readers are favoured with its description being neither more nor less than a twelve-inch-cube box. Our author is much "too cute" to give further details—these are only to be had on remitting him a couple of dollars. One almost fancies the delighted novice about to transmit the requisite sum to obtain this ne plus ultra, when in comes No. 611 of your valuable Journal. A glance at the contents shows the very thing he longs for—an article on "Bee-domiciles," the writer of which, without even once mentioning the great equilateral principle, after describing the hives of his own apiary, wishes to disabuse the apiarian mind, of what?—the fallacy that one hive can be superior to another! or to quote literally his own words, "That by no particular invention, contrivance, or theory, bees can be forced, as it were, to augment their sweets." This reasoning being subsequently complimented in your columns by no less an authority than "AN OLD APIARIAN," it is no wonder though the poor novice should be driven, as a last resort, to the purchase of some of those pretty expensive toys disposed of by parties as bee-hives, who surely know little of the subject, and into which the practical bee-keeper would never think of hiving a swarm.

That Miner may have found his equilateral-hive of a size suitable to the requirements of average swarms in the United States is possible enough; but it is simply absurd to argue that this size should be adopted in every case, be the swarm great or small. A small swarm hived in a roomy box must necessarily retain within it a greater number of workers to raise the temperature for comb-building, and, therefore, can spare fewer to go abroad foraging; this must materially affect their store at the end of the season, and contrast unfavourably with hives of smaller dimensions. As to large swarms, he admits having received communications from parties supplied, inquiring what they are to do with swarms his hives cannot contain. His advice in such cases is that the appearance of swarms at hiving time is fallacious; to place an inch block below each corner of the hive, and at the approach of the first cool weather they will draw within. Indeed, our author seems to consider those monster swarms which occasionally darken our apiaries, not as happy windfalls, but as monsters in the worst sense of the term; and goes on reasoning that swarms should consist of a certain number and no more; that "bees in a hive are exactly in a similar position to a body of mechanics in a workshop; that they must have a certain

room to labour in; and that all their labours are deranged by an excess of labourers!" Common sense, one would think, would naturally suggest to Mr. Miner, as a wise master tradesman, the propriety of extending his premises so as to afford his numerous and busy hands fair elbow room; but then farewell to the infallible size, and all the fine reasoning of this most amusingly egotistical of all bee-writers.

To take up the other extreme, or the any-sort-of-hive doctrine, the veriest tyro in bee-keeping knows that the mere possession of the best description of hive is not sufficient of itself to insure success; that he must people it with a strong colony, occupy a fair locality, and have some knowledge of management, before such can be looked for. What I hold is, other things being equal, there exists as wide a difference between some hives and their management contrasted with others, to accomplish for the practical bee-keeper his main end in view—viz., sending the finest honey first to market, as there would between one of our modern clippers and a bluff bowed old Dutchman in fetching home from China the first of the season's teas.

Who has not looked with pity on the congregated mass of bees clustering idly round the entrance of many a cottager's hive, it may be for weeks, at the very best part of the short honey season, while depriving hives in its immediate neighbourhood may be rapidly storing up the finest honey? I was once assured by a respectable party, on whose veracity I could rely, of his having, while the day was at the longest and the white clover in full bloom, weighed a set of his Stewarton-boxes containing a powerful colony in the morning early, and again at dusk, and found they had increased their gross weight by the almost incredible amount of 9½ lbs. in the single day. Or, take an illustration from my own experience. Some years ago, being desirous to test the cottager's with a more improved system side by side, I hived early in June a good prime swarm in a common straw hive; on the day following, another of nearly the same weight in a wooden hive, fitted with bars and slides and other improvements; they were of like cubic contents, and placed a few feet apart. The season being propitious, they wrought very diligently for the first four weeks, and young bees appeared much about the same time. They then both began to slacken their ardour, and block up the entrance, threatening swarming. To obviate this, I placed an eke below the straw hive—the plan pursued by cottagers, and on the wooden hive a super, drawing each end slide only; this had the desired effect in both cases, with this difference, that the inmates of the box went on with renewed vigour to the end of the season, the other in a very leisurely manner. The straw hive I could have sold for £1 to our parish honey dealer to run down its contents. From the box I took a super of beautiful comb entirely free from pollen or brood, weighing 20 lbs. nett; for this I could have realised 2s. per lb. (had I felt disposed to part with it), or £2, having my stock-hive to boot, which was worth to me another pound, as it stood over without a particle of feeding, and threw a swarm the following season nearly 1 lb. heavier than its more richly stored competitor, only one day later, or exactly a year and a day after each had been established respectively. Surely here was an "augmentation of sweets" not ascribable to any fortuitous circumstances, but solely to the hive; the management being up to the time of the threatened swarming much on a par in every respect.

The shortcoming in the one case is as obvious as the success in the other. The straw hive being wrought full of combs, and these stored with honey and brood, the inmates were compelled to lie idle and hang out. The eke prevented swarming by a timely supply of fresh air, and a little employment in extending their combs. This might add somewhat to the breeding space, but then storing was over with the exception of a little honey, as the queen's breeding relaxed towards the end of the season.

In the box-hive, on the contrary, the addition was afforded where most required; the detachment told off to take possession of the super at once eased the pressure on the stock; the honey gatherers plied all their energies to carry home to this cool receptacle the nectar abounding; the nurses busied themselves pulling the discoloured covers off their older preserves hard by,

* This singular old man (who, by the way, is almost as fond a lover of bees as was the great Huber himself), working fearlessly among them and very rarely stung, although labouring under the same infirmity. When in his prime he dealt in cattle, purchasing horses and cows guided solely as to age, size, and defects, by the same wonderful delicacy of touch that distinguishes his estimating the small though more irascible stock—being then, as now, *totally blind*. As a climax to the whole, in his later years he was more than suspected of systematically tampering with the game laws.

treating the youngsters to liberal supplies, keeping them at the same time in blissful ignorance of the nice white-covered sweets laid fast in the store closet up stairs (as thrifty housewives were then acting on the principle in larger domiciles); this gave an always-increasing area for fresh brood; hence the larger swarm from this hive the following season. Bees require no compulsion to augment their sweets; it is their delectation, the object of their lives—in short, their ruling passion. What they too often lack is but the opportunity. To the careful observer, it would appear the more they have to do the more they will do, with plenty of store room at command. Let but the golden moment arrive, be it a copious honey-dew or a change to the clover or the heath, how their energies are set on fire! with what a hurry-scurry do they pour forth! with what a too-busy-to-speak-to-you air they rush past—woe be to the luckless wight who at such a time gets in their way! how earnestly they toil—he must be an early riser who gets the start of them! and late in the gloaming, with what a done-up look do the last arrivals throw themselves on the landing-board and draw a long breath, before hurrying in past the wary sentinels.

Having already encroached far upon your valuable space, I must reserve till the next Number a detailed description of some of the "Bee-Hives and Appearances" having a place in the apiary of—A RENFELWSHIRE BEE-KEEPER.

(To be continued.)

OUR LETTER BOX.

HEN LAYING FROM PERCH (H. J. J.).—If your Brahma pullet will get upon the perch and deposit her eggs from thence, have your perch or perches made moveable, and take them away during the daytime. We will inquire about the cap forlop-eared Rabbits.

HENS NOT LAYING (An Old Subscriber, Dublin).—Fifty hens ought to give you more than nine eggs daily now. The food (one stone of potatoes and half a stone of steeped wheat daily) is more than enough for them, especially as they have a good run. Your hens, we think, must be old, or, if young, the eggs are taken either by themselves or other marauders.

HATCHING GAME BANTAMS.—(A Two-years' Subscriber).—You had better not have a brood until the end of May, or early in June. The chickens are tender. Turtle Doves, and, indeed, all the Columbaria, or Pigeon tribe, are good table birds.

HATCHING IN A STOVE (Inquirer).—You must keep the eggs at a steady temperature of about 104°. We should have them on a turf in a box, sprinkle them once daily with water, and covered with wool—a piece of sheep's skin, wool downwards. After all your trouble, you probably will not succeed; and if you do succeed in hatching them, then comes the redoubled trouble of rearing. Far better would it be to purchase a few old Cochins—China hens—they will set well, and are capital mothers. Your other query is answered in another column. No wonder that your Dorking cockerel, kept in a pen and fed on wheat, loses his feathers.

BLACKS IN FOWLS (A Constant Subscriber, Wigan).—Your fowls must be well treated with castor oil, a table-spoonful every other day. They should be fed twice every day with bread steeped in strong ale. When this fails to relieve, it is often necessary to bleed a little from the comb, and it should be done so that it shall not disfigure. So long as action is kept up by purgatives, any sort of stimulant may be beneficially given.

TASSELLED GAME FOWLS (W. P. Cooper).—There always has been a dislike to tassel Game as compared with others. Formerly there were the tassel and lark-crested. There are still some old fanciers who admire them when they see them, but, as a rule, they are not favourites. Mr. Daily treats of exhibition fowls and their treatment.

PLUMAGE OF GAME FOWLS (Gamester).—You can only change the colour of your birds by introducing stock possessing the qualities you lack. If, therefore, the fault is, that the colour does not exist, buy a cock where it is fully developed, and put him to your hens. If it exists, but lacks brilliancy, it is a question of cleanliness and condition. Feed well on ground oats and a few peas, and see that their roosting-places are kept clean. If the white you mention is a sort of fluff at the root of the feathers, and no part of the feathers themselves, it is immaterial; but if it is any part of the feather it is a disqualification. We hold that the red or copper saddle is quite correct in Duckwings, but not a red hackle. The last is a defect, and coupled with the fact that the hens are more like Black Reds than Duckwings, we should say they were cross-bred, and that some of the former blood was in them. We have hardly yet had Game Bantam hens quite perfect in colour as Duckwings; there is still some little latitude allowed to them, but none to the cocks.

FOOD FOR BARBARY Doves (Coo).—Wheat, barley, and hempseed; the latter sparingly. If sick, withhold the hemp, give bread and milk, and add any powerful bitter to the water. We were unable to obtain this information in time for last week.

BEES DESERTING THEIR HIVES (E. F.).—Bees sometimes leave their hives when in danger of starvation. Instead of waiting a sure death by famine, they appear to sally forth in the torrid hope of bettering their desperate condition. Liberal feeding last autumn would probably have saved all, or nearly all, your stocks, and may even now be necessary to preserve the two that still survive. Our correspondent has lost twenty-eight of thirty stocks.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 55.3° and 35.7° respectively. The greatest heat, 73°, occurred on the 14th, in 1852; and the lowest cold, 22°, on the 13th in 1853. During the period 122 days were fine, and on 116 rain fell.

MY ORCHARD-HOUSE.

HAT spring-like and charming weather on this Good Friday morning! How delightful the temperature of my orchard-house! How thickly my Apricots have set their fruit! and how beautiful are the Peach and Nectarine trees, all in full bloom! The thermometer hanging in the shade in the centre of the house marks 68°, which is most enjoyable to my feelings, for I always reckon that a temperature ranging from 65° to 72° is perfect, when accompanied by fresh air which is now gently breathing against my face.

My house is span-roofed and 14 feet wide, with glass on each side and at the ends, so that it is remarkably light. I never remember to have enjoyed my orchard-house walkings and doings as I have done this season; for ever since the severe frost left us in January, its climate has been so dry, so calm, and so agreeably warm after an hour's sunshine, that I have always felt loath to leave it.

I have been very fortunate in my management, and it may be interesting to some of your readers unlearned in orchard-house culture to know how I have operated on my trees. Early in November I had them all top-dressed, gave each tree a gallon of water, placed all the pots close together, and covered their surfaces with refuse hay 1 foot thick. On that terrible Christmas morning I went into my house with a comfortable feeling, for I felt assured that my trees were safe. To my surprise I found the thermometer inside registering 26° of frost, outside 2° below zero. Every shoot was frozen hard. I almost feared the blossom-buds would be injured by such excessive cold, particularly as the shoots were not so hard and ripe after the cool, cloudy summer. As soon as the frost left, or rather about the end of January, I had all the trees syringed with the Gishurst Compound, as it had just come from the manufacturer, and, as my man said, "smelt powerful bad." I dissolved six ounces to the gallon of water, and had them syringed with it till every shoot was dripping. I allowed them to remain two or three hours to get partially dry, and then had them thoroughly syringed with pure water, which, to a certain extent, removed the unpleasant smell: (but Mr. Wilson, the inventor of the Gishurst Compound, must tell us of some agreeable disinfectant, for its stench is marvellous). Well, I presume my syringing killed not only the brown aphids, which is often so active in winter on the young shoots of Peach trees, but also its eggs; for whereas last year after a frost in December, 1859, nearly as severe as the memorable frost of last Christmas, my trees were more or less infested all the spring by this pest, I cannot now discover one; and they (the trees) are perfect beauties—bushes of promise, for I grow them in the bush form in thirteen-inch pots, and pinched in their young shoots all last summer.

In a small way I am a collector of varieties of Peaches and Nectarines, and have some fifty or sixty sorts. I

No. 2.—VOL. I., NEW SERIES.

wish I could impart to your readers the pleasure I derive from not only their fruit, but in studying the infinite diversities of their leaves and flowers. No two are exactly alike; and when the eye is to a certain extent educated, the slight yet well-marked variations are charming, and fill the mind with that gentle, happy feeling of admiration so conducive to its health, so soothing to the unquiet spirit, so calculated to fill the heart with thanks for this foretaste of the glories of spring.

Among Peach and Nectarine trees, some give flowers large and almost gorgeous in the colouring; some only those that are bright in colour, yet with petals comparatively small; and others again flowers so small and inconspicuous as scarcely to attract notice. I have amused myself with looking over my trees and taking notes of their blossoms. It has been with me a slight labour of love; to your readers the reading of such notes may, perhaps, be real labour; but they may pass it over, or you may not think them worthy of the labours of the press. But here they are:—

Peaches with large, bright-coloured flowers.

1. Pucelle de Malines.
2. Early Savoy.
3. Princess Marie.
4. Barrington.
5. Shanghai.
6. Acton Scot.
7. Early York.
8. Abec.
9. Pavie de Pomponne.
10. Cooledge's Favourite.
11. Grosse Mignonne.
12. Early Grosse Mignonne.

These are all most beautiful, particularly Nos. 5, 6, 8, 11, and 12, which when in full bloom are glorious objects.

Peaches with large pale flowers.

1. Noblesse.
2. Newington.
3. Early Anne.
4. Red Nutmeg.
5. Malta.
6. Madeleine de Courson.

No. 6 is the Royal George of France, being cultivated there to the same extent as the Royal George is in England, and reckoned one of their first-rate kinds.

Peaches with small pink flowers.

1. Gregory's Late.
2. Early Tillotson.
3. Bellegarde (French Ga-lande).
4. Royal George.
5. Small Mignonne.
6. Late Admirable.
7. Catherine.
8. Chancellor.
9. Desse Tardive.
10. Walburton Admirable.
11. Royal Charlotte.
12. Angers Large Purple.
13. George IV.
14. Belle de Doué.
15. Monstreuse de Doué.
16. Belle de la Croix.
17. Salway.
18. Vineuse.
19. Violette Hâtive (English Ga-lande).
20. Boudin.
21. Crawford's Early.

Nos. 3, 11, 17, 18, and 19, have flowers of a very deep pink, and are very conspicuous and pretty. Many of the others in this list have very small, inconspicuous petals, some of them tipped with green; but no two are alike.

Nectarines with large bright flowers.

1. Newington.
2. Early Newington.
3. Pitmaston Orange.
4. Rivers' Orange.
5. Hardwicke.
6. Stanwick.

Nos. 3 and 4 are the most showy and beautiful of all, No. 654.—VOL. XXVI., OLD SERIES.

their flowers of the largest size, and of that bright rose colour always so agreeable.

Nectarines with large pale flowers.

- | | |
|------------|-----------------------|
| 1. Bowden. | 3. White. |
| 2. Roman. | 4. Fairchild's Early. |

Nectarines with small pink flowers.

- | | |
|------------------|----------------------|
| 1. Murry. | 5. Oldaker's Black. |
| 2. Late Melting. | 6. Balgowan. |
| 3. Elruge. | 7. Due du Tellier's. |
| 4. Impératrice. | 8. Downton. |

These, like the small-flowered Peaches, are very diverse in the size and colour of their petals, but Nos. 3, 6, and 8 are very bright and pretty.

When one considers that all this beauty is to be followed by fruit equally or more beautiful, it need not excite surprise that my love for orchard-house culture increases annually. Plums, Cherries, Apples, and Pears all have blossoms more or less varied; and when I have built separate houses for these fruits, which I hope one day to be able to do, I may give you a few more notes. I have felt much regret to see my friends, the bees, so weak and so chary in their visits. In most seasons there is one continuous hum; but not so this year. My bee-keeping neighbour, "Old Jack," tells me that his are nearly all dead: those are, or were, in common hives with the usual straw caps.—*AMICUS.*

RECENT SEARCHES FOR TRUE CINCHONA PLANTS.

BEING desirous of seeing the decoration of the hothouses for the million at Kew, and the effects of the frost on the vast variety of out-of-door plants there, I called about the middle of March.

As I got the length of the long succulent-house Sir William Hooker and Mr. Smith, the Curator, met me, both improving in appearance as they advance in years. And I am again indebted to their good natures for an opportunity of seeing every move in the place, accompanied by the heads of the separate departments to explain everything I wanted to know about.

The Orchid-houses, the new Cinchona-house, and some other places are now kept private, as the constant jarring of doors the year round is most prejudicial to that high style of cultivation in which all the rest of the house plants at Kew are seen. After taking particular notes of all the plants they force for decorating the show-house, of all the climbers, and all the plants which come naturally in flower in March—but above all, after selecting my own choice of kinds from their vast collection of Acacias kept, purposely to save room, in the smallest pots they will thrive in—I had more to do than I could spin in one week, and I thought of proceeding no further than the Acacias, and going a second time; but my guide, a good-humoured-looking man, invited me to see their newest house on account of the new way of heating it for bottom heat.

It is a very long house, in two divisions, and marked "private." I recollect seeing it in progress last autumn, and could see there was something extra to be tried, on account of the quantity of piping and the ways they were laid, and sure enough there was. I only wish you could have seen the writer on stepping into that house.

Well, the sight upset all my plans, and my flowers must now give way to doctor's stuff—to the highest department of the operative chemist, and for the use and profit of all others who feel the pulse of life.

I now recollect that when I was at Kew in the autumn there was a rumour among the young gardeners about a friend of mine, which I was sorry to hear, to the effect that he, my friend, had proceeded on false premises, and become embroiled with the Indian Government in London.

They, the Indian Government, resolved to strive to obtain the trees which produce the tonic barks of commerce; they wanted Bark trees—the trees which produce Jesuits' Bark, or Peruvian Bark—of which they make Quinine and other doctor's stuff.

These trees occupy thirty or thirty-two parallels of latitude in Peru, and to the north of it as far as Loxa. They range high up in the mountains far from the coast, and the same kind differs so much at different elevations, as our wall ivy does from flower-

ing ivy with its plain leaves, so that botanists who had to name them from dried specimens made a great confusion of species, which confusion is not yet got rid of.

Well, a collector from this country, to find out the best kinds of Bark trees, must not trust to his botany so much as to the practical experience of the barkers out there, who make a living by felling the trees, and harvesting the bark, and getting it to the coast—processes which last, more or less, from April to November. The Council of the Royal Horticultural Society, since they lost Mr. Douglas, held the opinion that a collector for South America would need to speak in the foreign tongues to get on at all, and would never trust any of us gardeners with such a mission to these regions. Now, this was the very leaf out of our books without our leave, which brought my friend, and the friends of India to the midst of the jungle. They sent out a foreigner who could talk about Cascarillas and Cortexes of all shades of colours, and all the rest of it. His name was ominous, too, being Markham. Mark every turn of the way from his office in London to Calisaya, the southern limits of Cinchonas—for that is the book name for these Bark trees; and one of the best kinds of Bark trees is named Calisaya, after the place where it is found. Mr. Markham was allowed a practical gardener, Mr. Weir, to carry his bag, and set his tent, if he had one. He was not long in filling his cases, and in bringing them over to Southampton, on their way to India by the Red Sea, green as Chives. Here my friend got scent of them, and he told the rest of us that Mr. Markham's trees were done as they do the bacon in Ireland, first killed and then cured; killed by a vertical sun in getting over the mountain passes to the coast, and cured with the salt mud of the nearest estuary, and if he had stopped there no harm could have come of it, for truth only was told us.

I once had a similar case. A number of boxes of Mexican fine-leaved plants were lying packed in Vera Cruz, under the French blockade, 1838, for two years and five months altogether, yet some of the plants were as green as grass; and a good judge of such things, Mr. Tait, of Sloane Street Nursery, reported them safe and sound, although they must have been dead over two years, and I was not surprised to hear that Mr. Markham was deceived in his collection. If he had, therefore, been silent till he reached India with them, he might have put the blame on the scorching heat over the Red Sea. But he did not remain silent, and my friend fell into a grievous error, and accused the India House people of squandering the public money in this expedition, without knowing the other side of the question—namely, without knowing that Mr. Markham had two strings to his bow, that he did not value his cargo of trees so much as the seeds of the same kind, which he ordered Mr. Pritchett, who is acquainted in the craft out there, to gather and send after him to Kew as soon as possible. This Mr. Pritchett found no difficulty in doing, and a large assortment of seeds of the various and best kinds of Cinchonas reached Kew on last Lord Mayor's day; and if all the seedlings of Cinchonas which I could not number at Kew, were sold now at five farthings a-piece, the proceeds would cover the cost of the Markham expedition, and leave something on hand for the relief fund for the famine in India.

Forthwith the Council of the Royal Horticultural Society advertised for a plant collector who could talk in the Spanish tongue, or in the language of Portugal, or both, and odds were soon staked on both sides of the race for Cinchonas.

The advertisements did not take, however, but they opened the eyes of Sir Charles Wood and his India Board to the perils of their progress for procuring tonics for the Emperor of China and his people; and a second expedition, on the true English model, was soon on its way to the Cinchona country.

The practical gardener who was known to possess the most needful qualities for a traveller for plants in foreign parts was sought out and soon found. We have such gardeners by the dozen in London itself. The authorities at Kew were entrusted to make the selection, and they fixed on Mr. Cross, one of their own recent pupils. You will certainly smile when I tell you of the qualities on which Mr. Cross's fitness was founded—that he was canny enough to know the value of the practical application of pluck on the instant. This quality Mr. Cross was presumed fairly to possess, as the lineal descendant of the very man who saved the life of Bailie Nicol Jarvie, the Glasgow magistrate, by cutting off the tails of his coat, from which the worthy functionary was dangling over a precipice from the boughs of a thorny tree in the pass above Aberfoil. I have

seen that application of pluck more than once on the right-hand side of the pass from Prince's Street to Holyrood, in Edinburgh, but I never could understand how it was done. Mr. Cross did understand it, however, and that will immortalise his name as the most successful collector of plants on record.

Mr. Cross left with letters of introduction to Mr. Spence, an English gentleman who has been out there for many years, and whose name is well known among naturalists in this country. After consulting with Mr. Spence, he engaged a man Friday, and set off to the hills, cleared a piece of ground for an experimental garden up in the forest, had a rumpus with a party of volunteers behind a stockade made on purpose to impede his mission through jealousy of trade secrets, which throw difficulties in the way of travellers, such as persons unacquainted with the Bark trade can hardly conceive. However, Mr. Cross and his man Friday surrounded them Aberfoyle fashion, made friends of them, and they fished him no more.

But the manner in which he botanised for the best species of Cinchonas is the best chapter in the whole expedition. Friday could dig, rake, pick off stones, and root-weed, and manage to water plants by this time if he had them; but that was the difficulty. There was no end of plants, but a great number of them are useless, except for the purpose of adulteration. The practice is to fell the trees, and cut as low as the crown of the roots, the very bottom yielding the best bark. This causes suckers and suckering-stools all over the forests that are frequented by bark strippers, who go singly or in gangs according to their numbers, and there is a major domo to receive the daily supply of bark from so many gangs, and see to the proper drying of it. The major domo knows the real value and the foreign quotations for the bark of every species which grows within the limits of his boundaries. His botany beats ours, small as pulvis quinquina, and his first-born daughter knows more than he—knows that his own men cheat him sometimes with inferior kinds of bark, more easily got at than the very best, which is more often on the highest and most inaccessible places in the ravines and mountain sides—knows also they must not come it so in her department.

Now, besides the damsel being fair, and setting aside the luxury of playing the gallant in the wilderness, a leaf out of the book of the daughter of the major domo would be of more value to Mr. Cross at that moment than all the writings on the Cinchonas from the days of La Condamine to those of Weddell, the first and all but the last, who wrote upon the subject. So Mr. Cross made up to the damsel and proved the fact (which had no need of proof, however), that the language of Nature, fresh from the heart and soft from the eye, beats all your foreign tongues to cloves and ribbons; and Mr. Cross had no want from that time of best Bark stools to select from—that you may depend upon.

Friday, too, took up the spirit of the thing, being kindly treated by massa and missa alike. The experimental garden was soon full, and the watering incessant. So many of the suckers came up as Irish cuttings are described—full of roots and flakes of soil, and so many without roots, but with recent wounds and the disposition to root induced by the felling of the tree, were fit subjects for experimental work. They did root, and between the two sets of cuttings there were enough.

Mr. Cross, however, like Mr. Markham, looked after the seeds of the proper kinds, sent them to Kew, and Kew sent some of them to all the foreign stations with which exchanges are made, and which had the right climate for them. The rest went to swell the seedlings which I could not number in the new Cinchona-house at Kew.

At the end of ten months Mr. Cross was back to Kew with six hundred plants fresh as when they left the Experimental at Huancoco. They were in fifteen cases, and from 9 inches to 2 feet long—such young stuff as most nurseries might be proud of sending out. They were all unpacked, aired, and tended for ten days or a fortnight; then repacked, and he was off with them down the Red Sea to India, by the time of my visit, and I could not help regretting that any friend of mind, or anybody connected with the reminiscences of Chiswick, should have founded a cause for ill will on these, the most complete, and the most likely to pay of all the trials of the kind that have been made in my days.

My reading on Cinchonas furnishes me no later dates than 1857, and yet I found a new species named at Kew, at least new to me and my books, in the "Materia Medica" (fourth edition, 1857), by Professor Pereira. The books and memoirs without

end that have been written about Cinchonas, are condensed into the smallest space, and that is the best digest of them, that I have seen. But this new accession of living species, and the fresh specimens at Kew from the aforesaid expeditions, will soon put the question on a new footing. Depend upon it, before ten years are over your head the Cinchonas will be good trade plants in the London nurseries, and will be ever and constantly in demand for exportation, and no one can say now but the basin of the Mediterranean may not compete yet with India for Quinine Bark.

It is only in hilly countries that the Bark comes to perfection. Pöppig, one of the best authorities on the subject, relates that many speculating merchants have been ruined in Peru by purchases of lowland Bark. The best Bark is found, according to Friday's friends, on mountain-tops, and on single trees growing in the coldest and most exposed elevations. The same kinds of trees grow low in the mountain-valleys, and in some parts low nearer the coast; but the bark from such situations is of no value except for adulteration. The kinds or species of Cinchonas from which such quantities of seeds were sent to Kew are Cinchona Condaminea, C. calisaya, C. nitida, and two varieties of micrantha—all well-known old species for producing the best Barks of commerce, and a new one called succi-rubra, and of this alone there are thirty or forty thousand plants pricked off! The seed-bed was made as for sowing Rhododendrons, to be sown broadcast along the front of the storehouse and over the hot-water-pipe; and it was 17 yards long, the whole length was sown broadcast, and the seedlings came up thick as grass. There is no end to them, and succi-rubra is believed to be the best of them all; but Condaminea, micrantha, and calisaya were said from the first to have been the best. Condaminea is that which furnishes the pale Bark of English commerce; and Humboldt says this is the fine Uritucinga Bark originally seen by La Condamine, after whom it is named. Micrantha is the favourite Bark of the people of the country, who call it Casca-rilla fina, or the finest Bark. Nitida has the disadvantage of one name to two kinds of plants; but the nitida brought to Kew is the lanceifolia of De Cudolle, who makes nitida, officinalis, lanceolata, glabra, and angustifolia all synonyms of lanceifolia. It furnishes the orange-coloured Bark, and, next to Condaminea, is reckoned the best of all the species. Calisaya is said to be the source of the true royal yellow Bark, the China regia vera of English commerce. What may be the value or virtue of succi-rubra I never heard. But the whole subject is being recast just now; and a splendid folio work on these Cinchonas is in the press, under the most practical hands—one of the first firms in London for grinding the Barks, and the ablest heads in botany, who can now obtain fresh specimens of all the kinds if they need them almost by return of post.

D. BEATON.

REPORT ON SCARLET AND OTHER BEDDING PELARGONIUMS,

GROWN AT CHISWICK IN 1860.

By THOMAS MOORE, F.L.S., F.R.H.S., Secretary to the Flora Committee.

THE season of 1860 having proved unfavourable to these plants, it has been determined to renew the trial of them in the present season, and, as far as it can be done, to prove them also under pot culture. The brief particulars noted concerning them, and which embody the opinion pronounced by the Committee, though influenced to some extent by an exceptional season, may, nevertheless, be worth recording. They are to be understood as applying to the varieties as grown in the open air, and in many cases are derived from single plants.

The following is a summary of the varieties which the Committee adjudged to be the most desirable for cultivation:—

Series I.—PLAIN-LEAVED SCARLET PELARGONIUMS.

§ 1. *Flowers scarlet*:—Frogmore Improved, and Punch. Defiance and Wellington Hero, in addition, were commended for pot culture and for training up conservatory pillars.

§ 2. *Flowers cerise*:—Beauté de Meldeise, Lady Middleton, Le Titién.

§ 3. *Flowers rose-pink*:—Christina, Rose Queen.

§ 4. *Flowers white*:—The only variety of this colour was considered inferior.

Series II.—HORSESHOE-LEAVED SCARLET PELARGONIUMS.

§ 1. *Flowers scarlet*:—Baron Hügel, Captivation, Liliput,

Martin Gireau, Queen of England, Scarlet Perfection. Bishopstowe, Conway's Royalist, and New Globe were selected as good secondary sorts; while Amazon, British Flag, Compactum, and Richmond Gem were commended for pot culture or pillars.

§ 2. *Flowers cerise*.—François Chardine, Mons. Martin, Rubens, and Sheen Rival; and for pot culture, Paul Labbé.

§ 3. *Flowers salmon or flesh-colour*.—Prince Louise of Hesse; and for pot culture, Aurora and Blackheath Beauty.

§ 4. *Flowers rose-pink*.—None of the varieties in this group were considered of first-rate character.

§ 5. *Flowers blush with pink centre*.—Henri de Beaudot.

§ 6. *Flowers white*.—Madame Vaucher, and Nivea floribunda.

Series III.—NOSEGAY PELARGONIUMS.

These all have zonate leaves. The best sorts were Crystal Palace, Imperial Crimson, Pink Nosegay, and Red Nosegay. Of good secondary sorts, of larger growth, there were:—Bishopstowe Nosegay, Purple Nosegay, and Salmon Nosegay.

Series IV.—IVY-LEAVED PELARGONIUMS.

These were all considered to be useful bedding plants for various purposes.

Series V.—VARIEGATED-LEAVED PELARGONIUMS.

§ 1. *Leaves golden-edged*.—Golden Chain and Lady Cottenham were pronounced to be useful varieties.

§ 2. *Leaves silver or cream-edged*.—Of the scarlet-flowered sorts: Annie, Alma, Bijou, Burning Bush, Countess of Warwick, Julia, Perfection, Scintillatum; and for pot culture, Picturatum. Of those with cerise scarlet or rosy-tinted blossoms: Flower of the Day and Flower of Spring, both first-class sorts. Besides the foregoing, Lilac Variegated and St. Clair, both with pink flowers, were considered useful varieties of secondary rank.

The varieties having the whitest-edged foliage were:—Alma, Bijou, Jane, Mrs. Lenox, Mountain of Light, Mountain of Snow, and Perfection.

Series VI.—HYBRID BEDDING PELARGONIUMS.

The varieties of this group did not succeed as bedding plants in 1860.—(*Proceedings of the Royal Horticultural Society.*)

GROWING SPECIMEN PELARGONIUMS.

(Continued from page 3.)

TRAINING.—The plants, after being potted and properly treated by gentle waterings and syringing after a warm sunny day, will grow rapidly and strongly. Such being the case, the training to form a specimen should be commenced forthwith. The safest plan is to place slender sticks, painted green, one to each branch, and so to place them that the shoots may be drawn downwards, and at equal distances from each other. Strong shoots should be more depressed than weak ones in order that the strength of each should be equalised. If, notwithstanding this bending-out of the perpendicular, any shoot should still retain more strength than the rest, then nip out the uppermost bud of it alone—that will check it effectually.

Some varieties break close to the soil without any stopping, whilst others are very shy at branching out naturally. Such should be topped at the earliest stage of growth, in order to fill up the intended form. If the shoots grow too rapidly it is a sign that they have too much heat, too little air, and too much water. These must all be regulated according to the strength of the plant.

Some recommend having a centre shoot tied to a stick and side-branches from that central shoot. For a pyramidal form this is a good method; but to form a nice compact specimen like the one figured, no central shoot should be trained at all. The centre is sure to be filled up with shoots from the main branches. The weaker side shoots should be trained and drawn in, as it were, to form the centre of the bush. They are sure to be strong enough eventually.

Some also recommend a wire to be fixed round the pot, and matting used to tie down the shoots. This is a neat way, but there is danger in drawing down the shoots. I have seen a promising specimen spoiled by one or more of the shoots so tied down slipping off at the junction with the main branches. Sticks are certainly the safest and best trainers, for they can be lowered gradually so as to prevent the shoots having too sudden a strain upon them. Besides all this, plants trained with sticks may be more easily repotted than if trained with any material fixed to the pot in which they are growing at the time they need more

pot-room. All young specimens should have their blossom-buds nipped off the first season.

SUMMER TREATMENT.—As soon as the greenhouse becomes too warm for these plants, they should be set out of doors on a bed of coal ashes, and a shelter contrived for them to keep off the heavy rains. Rather less water should be given and the syringe hung up in the tool-house so far as these specimens are concerned—in fact, they do not need it now at all. The grand point to aim at is to get the wood well ripened. It should by the end of July be hard, firm, and woody, and of a dark shining brown colour. The leaves should begin to turn yellow, and the older ones drop off—in fact, it is the autumn with the Pelargonium. As soon as this state of rest is attained, then set the plants out of doors fully exposed to the sun, and in a short time they will be ready for the operation of

PRUNING.—This is an important point requiring considerable thought and judgment. They should be pruned at two or three seasons. For blooming early get the plants into the proper condition of ripeness early in August, prune a second lot a month later, and the last the first week in October. As soon as the plants are ready, cut them in according to their strength, and the form you intend them to take the following season. Weak plants should be cut in pretty close to one bud, stronger may have three buds, and very strong ones four or five buds each, and let each shoot when cut be at equal distances from the

Fig. 3.—One-year-old Pelargonium, pruned in autumn, and five shoots left to branch out the following year.

Fig. 4.—Two-year-old Pelargonium, pruned in autumn, and fifteen shoots left to branch out the following year.

adjoining ones. When pruned remove the plants into a frame set on bricks, so as to admit air amongst the pots. Keep the glass on day and night; but shade from hot sun, and give no water till fresh shoots have made their appearance, and the leaves have attained a little size. Then give a little water just to moisten the soil. They are then ready for the autumnal potting. It is sufficient to say that this potting is done as advised above for the spring potting, with this difference—that the plants are put into less instead of larger pots, the object being now to induce a large crop of blooms rather than larger plants. To get them into less pots it will be necessary to lessen the balls: hence they should be potted when the soil is rather dry, because then it is the more easily got away

from amongst the roots. Pick out all the old drainage, and prune in the roots also. Then when the ball is lessened, the drainage removed, and the roots pruned in, the plant can be easily got into a lesser pot. The soil to be used now should be pure loam and sand with a small addition of leaf mould. This will grow the plants well through the winter, and keep the leaves healthy enough. Replace them in the frame, and give but little water till the roots have spread into the fresh soil.

WINTER TREATMENT.—Towards the middle of October the plants should be brought out of the frame or pit and placed in the greenhouse. Here keep them growing slowly, and let the atmosphere be dry and not heated above 45° by day, and 40° by night. Be careful that no drip falls upon the leaves either by day or night. This slow-growing cool treatment will keep the plants stiff, bushy, and healthy, ready in the spring to start with vigour in growth, and set with bloom abundantly. Towards the middle of January, those intended to bloom in May should be repotted into their blooming-pots. In the next month repot such as are to bloom in June; and a month afterwards the remainder to bloom in July. Use the richer compost for these spring-shifts. As the growth proceeds, attend to the thinning-out the shoots where they are too thick, and place sticks to train the shoots that are left into one proper form. Early attention to these points will save a large amount of trouble afterwards. When buds are fairly visible, then give for every third watering weak liquid manure, increasing the strength as the leaves and blossoms advance in growth.

TREATMENT WHEN IN BLOOM.—It is scarcely necessary to say, when the flowers are open shade them from the sun, but some may not think of it. By shading, the blooms are protected and the season lengthened; without shading, it would be almost impossible to get out a blaze of bloom such as was seen on the specimen as shown in our woodcut. By attending to the above points of culture, and with persevering attention in keeping down insects, any grower with moderate means may produce, if not quite as fine, yet nearly as fine, a specimen as we have drawn their attention to.

T. APPLEYBY.

NEAPOLITAN VIOLETS FOR WINTER OR SPRING FLOWERING.

TAKE off cuttings as soon as the plants have done flowering in May, and plant the cuttings under hand-glasses in light garden soil at the foot of a south wall. Water and shade them. When they have struck root take off the glasses.

The first week in August prepare a bed the size of the frame intended to place over them. Put, first, a layer of broken pots or brick rubbish 9 inches deep; on this put 4 feet of leaf mould, 1 foot of free loam, 1 foot of thoroughly decayed manure, half a barrowful of clear sand, the same quantity of bone dust well mixed together. The plants should not be more than 15 inches from the glass.

Trim off all the runners from the plants before planting them in the bed. Keep the light off the frame during the autumn, except when very wet and cold. Place a layer of dry litter round the frame to prevent frost injuring the plants. When they begin to bloom never give air. Pots of plants put in any convenient place not above 65° will do very well, and a succession may be had from October to April.—J. B.

BROCCOLI, AND WHAT LAST WINTER TAUGHT ABOUT ITS VARIETIES.

As the season is at hand for sowing this all-important vegetable, it would be well to take a retrospect of the past season as contrasted with former ones, in order to arrive at a just conclusion which kinds it would be most proper to cultivate; for the past winter has disclosed many things we previously had but little idea of encountering again, and possibly many young cultivators never experienced the like before. Such a season may recur again: therefore it would be well to consider how far its evils in destroying so large a portion of our winter and spring supply of this vegetable can be avoided, and a better prospect opened out for a more efficient quantity in future.

In taking this line, it is advisable to look more particularly into the merits of the distinct kinds now generally cultivated, and from amongst them select those most likely to meet the requirements of a family in winters like the past, as well as in

seasons of less severity, like those of the three or four preceding ones. In doing this we need not go into the early history of this vegetable, which, doubtless, is enveloped in the mysteries of ages when horticultural records were less known than at present. Suffice it to say that Broccoli, as well as the Cabbage, Cauliflower, and other plants, are supposed to have all a common origin, but that their present difference and the regularity with which each kind produces its like from seed have been acquired by a long series of careful cultivation; and the different properties they present have in like manner been preserved to them by the same assiduity—but it is also certain that some of the properties of the original have been lost by this careful improvement. The finest Broccoli is far from being such a hardy plant as its progenitor, neither is it so hardy as some kinds less fine. The improvement here made is like that of the highest-bred animals—it is obtained at a sacrifice of constitution; and however much this may be attempted to be modified by intermediate means, still the improved breed is more tender than the original; and in Broccoli the most delicate in flavour are those most affected by the frost, and consequently they ought not to be planted in situations where a severe winter may be expected. But as there are several varieties more likely to do good service in such a place, it would be well to take a view of them and explain the merits of each; beginning with the one which in mild seasons is very serviceable, and noticing a few of such sections as it is advisable here to divide them into.

The Cape Broccoli.—The White variety of this differs but little from the Cauliflower in its inability to withstand frost. The Pink and Purple are a little hardier, but neither of them are to be depended upon after the thermometer falls below 24°. A single night at that degree, or even a little less, may not entirely destroy them, and if mild weather follows they may overcome it and keep on growing; but the Cape is not a variety to be depended on in cold bleak districts. It, however, has its merits. As an autumn variety it is unrivalled, and, being of more quick growth than most of the others, need not be sown so early. I have seen some that were sown at the end of June do very well, and even some of a week later than that have done so; but the middle of June, or from that to the 20th, is as late sowing as is generally advisable. One or two sowings before that time will have given an earlier supply, the seed being sown in the usual way care being taken to keep birds away; and if the weather be very hot and dry, a slight shading and watering will be beneficial.

The Walcheren Broccoli.—Some years ago an eminent gardener, well known as a successful exhibitor at the metropolitan shows, affirmed that he could supply his employer's table every day in the year from this Broccoli alone; but as the two or three winters we had at that time were mild, it is questionable, and had he lived till 1861, there would have been a long blank, probably as I do not hear of any one saving any plants of this variety the present season. Nevertheless, in general it is a useful Broccoli, harder than the Cape; and in moderate weather it grows more than most kinds do, and thereby affords a succession. In habit it differs widely from the Cape, the leaves being not so upright and more undulating—in some cases almost amounting to a fringe. When advancing into growth, however, some of these leaves turn in and protect the head a little from the frost. But this shelter is not enough at all times: it is, therefore, better to put a handful of dry straw or hay into the centre of each, in the event of a severe frosty night; or, what is still better, if the plant could be taken up and planted somewhere under cover, but not in the dark. Where there is accommodation for this, a supply is much easier kept up; but as this is not always the case, the homely makeshift above alluded to may be of service. Appearances in the garden at this inclement season being of less moment than appearances at table, it may be done to all kinds of Broccoli so far advanced as to take harm from the cold weather following. The sowing of this variety must be a little earlier than for the Cape. The early part of June is a favourable time; and once before that and once after may keep up a succession. Closely related to this variety are several, as *Snow's Improved*, and a winter Broccoli; but the characteristics of the Walcheren are a short stalk well clothed with leaves, and these of rather a robust description. The longer-legged kinds, though good in their way, are more liable to injury from the cold and frosts of winter.

The Hardy Winter Broccoli.—Under this head I purpose to include varieties widely differing from each other in every particular excepting in their capabilities of withstanding cold; but

as this qualification is an important one, we may safely regard this section as of much value. And if necessary they might be divided into subdivisions if these multiplied classes be required; but for present purposes two or three types only will be given. The first of these being the Purple Sprouting Broccoli, which appears to be a sort of hybrid between an ordinary Purple Broccoli and some of the Greens, or Kales; for the small sprouting heads are more or less intermixed with leaves, giving it some of the features of some of the many-headed kinds of Greens—these leaves, however, acting as a great preservation to the head in excluding frost. A good variety of *Sprouting Broccoli* ought, therefore, always to be cultivated to some extent, proportioned to the situation and other circumstances of the place—most abundantly when the situation is a bleak cold one, and *vice versa* when it is the contrary; for it is not so much admired at table as a delicate White Broccoli, but is admissible when other kinds are not forthcoming. Next to this is a variety called *Protecting Broccoli* with some one's name appended. These are generally of medium height in the stalk; and being furnished with a profusion of leaves, the inner ones form a protection to the advancing head by concealing it more than other varieties generally do. The most common colour is a cream or brimstone for the head; but a good pink or pale purple is sometimes had with this quality. It is, however, not so hardy as the Sprouting, but is more esteemed at table, and ought always to be grown more or less. It is needless here mentioning varieties, as those most in fashion at the present day may be eclipsed by others next year. Another section of winter Broccoli is one that has fallen much into disrepute of late years—the old *Purple varieties*—the heads never very large, being more rounded and even-pointed than flat, the leaves curly, and the plants tall. It is now some years since I saw a really good variety of this: the attention of cultivators being directed to the growth of the White and Cream varieties, this useful hardy one has been neglected. Some thirty years ago I remember that *North's Purple* was one of the most useful kinds grown, and having seen it survive winters that killed the White kinds, I should be pleased to hear of some one presenting us with a really good hardy Purple Broccoli again. The Pink class is rarely so hardy, those that I have seen presenting much the character of the Cape and kindred varieties. All the winter ones ought to be sown by the end of April or beginning of May. In late places they cannot be sown too early; in more favoured spots May will be soon enough.

The Large Varieties of Spring Broccoli.—There is no lack of names to this class; and broad hints have at times been given that several high-sounding names are often given to the contents of one bag of seed. The *Portsmouth*, *Mammoth*, *Southampton*, and *Brimstone* may all and each be taken as examples of the class I allude to; noble, finely formed heads of great size coming into use at the end of April, or earlier if the spring be favourable, and all noted for the closeness and symmetry of their growth. But there will be few of these in the present season in the majority of places, as, the plant being tall, receives little protection from the snows of winter unless they be deep; and if much injured by the winter, the head is proportionally smaller, and very often the whole plant is entirely killed; but when the plants do live through the winter with little injury, the noble-looking heads they present us with are justly admired. They may be sown from the middle of April to the first week in May; but as much depends on the after-treatment they receive, a week or more are either lost or made up by their after-cultivation.

The Late Varieties of Broccoli.—Like the hardy winter sorts, these are of various kinds, but generally dwarf. I have grown a variety for some years called, I believe, originally *Boules' Late Broccoli*, but it has disappeared in the seed lists. Its characteristics are a dwarf habit, wrinkled, and much undulating leaves, and the head more like a half globe than flat; but neither in this nor yet in the size of the plant is it large, and may in consequence be planted closer than may larger kinds. I believe the *Wilcore* to be much the same variety; and, doubtless, there are several others having these properties. It does not come into use all at once, as *Miller's Dwarf*, the *Russian*, and *Danish*, or other varieties of that kind do; but, like the kinds previously enumerated, it comes in gradually, and, consequently, is more useful. Its extreme lateness is also a good quality, for we often have it in use until a very few days prior to the first spring Cauliflower is cut, sometimes not more than four days. It is also hardy, though not perhaps quite so much so as the Russian,

Danish, and *Miller's Dwarf*; but as these all come into use in one week, their utility in ministering to the wants of a family is much diminished: nevertheless, they are the hardiest of all our winter-standing Broccoli, and, being small, may be planted closer than some kinds. Sow all the above as early in the season as convenient. And though they are often planted amongst growing crops during the summer months, yet let them be well inured to the weather before winter sets in, and they ought to have made considerable growth before then.

GENERAL REMARKS.—*Protecting Broccoli in Winter.*—Where there is the convenience of a cold pit, with a covering of some kind or other, a quantity of plants that are about forming their heads may be lifted with balls of earth, and planted in this pit tolerably thick. By this means a succession may be kept up in the severe weather. But as every grower has not the convenience of a cold pit, and structures of that kind may be occupied with something else, it is better to adopt some other plan. A slight covering with dry straw will keep off a severe frost, and is easily accomplished; and a good old-fashioned plan of partly laying the plants on their sides tends to protect the crown very much. The method is this—Supposing the rows to run north and south, begin at the west row, and take a spit of earth out from the collar of each plant on the west side; and having done so, bend the plant gently to that side, and, taking a spit of earth from each plant on the second row, lay it on those that are bent down; and the same course being followed by the third and succeeding rows, the whole plot will have the appearance of plants laid down in a slanting direction, and, being all pointing westward, they do not receive the morning sun direct on their crowns. Certainly the tall varieties of Broccoli keep better this way than when standing upright; and though they eventually bend and turn upwards, the hard weather is usually gone by that time.

Conditions Necessary to Enable Them to Stand the Winter.—Plants that have been encumbered by peas, scarlet runner beans, or other high crops, which are only removed on the eve of severe weather, have but a poor chance to withstand it. Neither are they in a good condition when their growth, owing to the mild weather and richness of the ground, is prolonged to the period when severe frosts set in. This latter evil was one of the causes of the severe losses everywhere complained of in the past winter; but it is also wrong to allow peas and other crops to draw Broccoli up into a sickly growth, and perhaps expose them suddenly at a time when shelter is more needed. Another thing ought also to be mentioned here—a piece of rich ground is not the best place to insure a healthy and hardy growth capable of standing much cold, although, in general, such soils will produce the best Broccoli; but dry, poor soils have a tendency to harden the tissue of the plants, and they being more in a condition which we call “ripened,” are more capable of bearing the cold of winter.—J. ROBSON.

POTATO CULTURE.

A RECENT writer, in an article on Potato disease, wisely proposes planting in double rows on ridges as more convenient for covering and laying down the haulms, which he contends is a preventive in a great measure of disease. This of course (if extra space is given between the double rows), gives better opportunity for raising sufficient mould for that purpose. This he affirms prevents the fungus, &c., which first appears on the blades, from descending to the roots and tubers. Although I am sceptical of this being a specific remedy, allow me to add, in confirmation of the utility of planting on ridges with wide intervals, that I have for several years succeeded well with early kinds by planting in double rows between my celery-trenches, after the trenches had been prepared. At the last operation of forming the trenches, when the celery is about to be planted, the haulms are pressed down with the spare mould on each row toward the trenches. The tops thus hang down on the sides of the ridges attracting the fungus, &c., from the haulms, and draining excessive moisture from the roots into the celery-trenches, where it is absolutely always much needed.

I strongly recommend the practice in garden compartments, as it interferes but little with the celery crop, and secures an early and sound crop of Potatoes, where but little else is commonly grown. The mould where the Potatoes grow is not required for the celery till the Potatoes are cleared off. The first and second earlies may thus both be cultivated with advan-

tage: No. 1, such as Ash-leaves and Frames, growing between the first plantations of celery; and No. 2, such as Flukes and Flour-balls, &c., between the second or later plantations. Where celery is not required in quantity, I recommend that after the ground has been well prepared in the common way on the flat, by manuring and deep digging, to form it into ridges 4 feet wide, and thereon to plant double rows of Potatoes to be treated in a similar way as I recommend for those between the celery. In the centre of three-feet intervals, I would reserve one-foot-and-a-half spaces for double rows of successional crops of Peas, and Scarlet Runner Beans, to be sown in May and June. Where Broccoli, Cabbages, Savoy, Cottager's Kale, Green Kale, Thousand-heads, &c., are required, let the ground be formed into complete seven-feet ridges, still adhering to double rows of Potatoes on the top or centre, with the furrows, or lowest parts, reserved for double rows of the Cabbage-works; to be planted in June or July, right and left of the said furrows, to be moulded up during autumn with the mould from the Potato-plots, as a preventive or protection from excessive wet and frosts in winter. Thus six-feet spaces will be allotted (and it will be found not too much), from one outside Potato-row to the next, or three-feet spaces from the Potatoes to the Peas, Beans, Cabbage-works, &c., changing the furrows in winter to where the Potatoes grew in summer.

By reversing or alternating the crops next season, no one kind of crop would be grown on the same ground as it grew upon the year before. In field culture all the practices of digging may be substituted, and with equal advantage, by deep ploughing, whether it is for Potatoes or other crops with the same wide spaces, either late planted, or fallowed (if foul) for similar crops the next summer, at the will of the cultivator.—A HARDY, *Maldon, Essex.*

LEEDS SPRING FLORAL EXHIBITION.

AN exhibition of early spring flowers, such as Hyacinths, Tulips, Narcissi, Cinerarias, &c., is rather a novel idea. A decidedly successful one for the first time took place on Wednesday, the 20th of March last, in the magnificent Town Hall, at Leeds in Yorkshire, originated by Mr. T. D. Appleby, the indefatigable and enterprising manager of the floral and horticultural fêtes in that emporium of the woollen trade. Though the day was unfavourable, the company in the afternoon was numerous and fashionable; and in the evening the large room was crowded, showing the spring flowers are equally, if not more, attractive than those of summer.

Nurserymen, gentlemen's gardeners, and amateurs vied with each other, and certainly the display did them great credit. The flowers were all, with a few exceptions, in pots, and arranged on a platform down the centre of the room, the Hyacinths and Tulips filling one side completely. A bank of those lovely spring flowers nearly 100 feet long, was a truly beautiful sight. The odour from the Hyacinths perfumed the air, filling that large Hall with their agreeable scent. On the other side the Narcissi and Cinerarias, and some splendid dishes of cut flowers, chiefly Camellias and Azaleas, placed in dishes in wet sand, were almost equally effective. On a long table in front of the orchestra there were placed the collections of Azaleas, Camellias, and miscellaneous plants, all in good bloom.

In single specimens the most remarkable were a most beautiful new Caladium, in the way of *C. argyrites*, but much handsomer and larger foliage than that little gem. This came from Mr. Franklin, gardener to J. G. Marshall, Esq., of Headingley Hall, the successful raiser of *Begonia Marshallii*; also, a grand specimen of a tree *Mignonette*, the giant variety grown as a standard, with a stem 3 feet high, and a head covered with large spikes of its fragrant blossoms $1\frac{1}{2}$ foot high, and as much through; also, an Indian Azalea, exhibited by Mr. Dymont, gardener to W. G. Joy, Esq., of Headingley, was 10 feet, a perfect pyramid of white blossoms. The collection of Azaleas exhibited by Mr. E. Thompson, were well grown and splendidly bloomed. As much cannot be said for the Camellias, accounted for by the gardeners as owing to the wet autumn and severe winter having caused most of the buds to fall off generally throughout the district. Music added her charms to the enjoyment of the visitors; Spencer's well-known operatic band being in attendance. The extending the hour of closing the Exhibition till ten o'clock, gave many of the tradesmen and warehousemen an opportunity of visiting the Exhibition, though, no doubt, some little inconvenience to the exhibitors, especially those that came from a distance, was occasioned thereby. The Hall when lighted up with gas showed

off the flowers to a much better advantage than the dull, wet day did. The greatest and most successful exhibitor of Hyacinths Tulips, Narcissi, and Cinerarias, was Mr. W. Dean, formerly manager for Mr. C. Turner, of Slough, but now established as a nurseryman on his own account at Shipley, near Bradford, in the same county. He deservedly obtained the first prize for twenty-four Hyacinths; and as many of our readers may be desirous to know what kinds do well in pots, we noted down a few of what were considered the best.

In *Double Reds*, the best was Lord Wellington, not high in colour, but with large bells and a good spike. Princess Royal, fine red, with deeper stripes; very large bells and spike. *Single Reds*, Robert Steiger, deep crimson bells; large and good spike. Madam Hodson, pale pink; a fine spike, and large bells. Norma, flesh colour; very excellent both in spike and bells. Belle Quirine, also flesh colour, but deeper striped with carmine; fine spike, and large bells. *Double Blues*, Glory of Albion, light bluish-purple; long, close spike, and bells very large; a fine variety. Prince Frederick, striped bluish-lilac—a novel and beautiful colour; a good variety. La Fontaine, light porcelain blue; good dense spike, large bells, and fine in quality. Laurens Coster, shaded purple and blue; large, fine spike; one of the best varieties. Blocksberg, pale lilac striped with blue; an old, good variety. *Single Blue*, Argus, indigo blue, with distinct white centre; a new and very striking variety. Baron von Tuyl, dark porcelain blue; large bells, and very fine spike; one of the best. Couronne de Celle, porcelain blue; extra large bells, and long spike; a beautiful, good variety. Grand Lilas, delicate azure blue; large bells, and very large spike; excellent. Lord Raglan, shaded porcelain blue, darker than Charles Dickens; good bell, and large spike. Prince Albert, rich, glossy, blackish-purple; good bell, and very large spike; the most striking Hyacinth exhibited. *Single White*, Elfrida, blush white; large well-shaped bells, and a good spike. Madame de Staël, the purest white; with good bell, and fine spike. Madame Van der Hoop, pure white; fine bell, and extra long fine spike. Voltaire, blush white; very large bells, and good spike.

Tulips were in great force. In Scarlets nothing could be better grown or more splendid than the variety of Van Thol named Vermilion Brilliant, a splendid high-coloured kind which everybody ought to grow. It is excellent either for forcing in pots or for the border.

The *Narcissi* were not very numerous, but very well bloomed. Louis le Grand is a rather new kind, and is a pure white. The old Grand Monarque was in good feather, and keeps its place as a fine easily-forced variety.

The collections of *Cinerarias* were well-grown dwarf plants, and exceedingly well bloomed. The best came from Mr. Dymont. In this class of early flowers Mr. Dean submitted several new seedlings, and the Judges unanimously selected the following as being new and quite distinct from any now in cultivation:—

Crimson Gem, a self of a deep rich crimson colour, finely formed, the petals broad and firm, and the disk rather large, and of a dark colour.

Kate Appleby, a nearly white self, with a dark disk; the petals very broad, and the least imaginable tipped with pink; a delicate, desirable variety.

Mrs. Appleby, white ground, broadly margined with crimson; fine form, quite flat and circular; good habit.

Mrs. George Edwards, white ground, broadly margined with purplish-crimson; dark disk; form good, and habit dwarf and compact.

Lady Fairbairn, white ground, delicately margined with scarlet; the best of its class; form perfect; habit good.

From the fact that an early spring show in a provincial town for the first time being successful, it may be fairly assumed that the next at the same season will be still more appreciated; exhibitors will be better prepared. At this time of the year a good display of forced flowers is highly attractive, and in addition this is the right time to have a splendid exhibition of that noble flower the Camellia.

STRAWBERRY PLANTS FOR EARLY FORCING.—The general practice of preparing Strawberry plants for early forcing, is to secure the earliest runners of the current year, and transfer them to their fruiting-pots as soon as possible. I may safely say this practice requires a great deal of attention and good treatment to obtain strong well-matured plants before the winter of same year. The practice I have followed successfully for two years

is to peg down a sufficient quantity of runners any time in June. When sufficiently rooted lift them and transplant them in nursery-rows on a piece of ground in good condition, having a south aspect preferred (with me), there to remain all winter and next spring, until the end of May or beginning of June. Lift them with moderate balls, and plant them in six or eight-inch pots, according to strength of plants, in good rich soil; then plunge the pots up to the rim in coal ashes or sawdust in a sheltered situation exposed to the sun, paying attention to

watering the plants. They may safely remain until the approach of winter, when they should have the protection of a glass frame or other convenience, from whence they may be taken to the forcing quarters as occasion requires. The plants will be greatly benefited by giving them a surface dressing of rich loam early in November. By this treatment the plants will give satisfaction. Not having seen or heard of this method being practised, I thought it might be worth the notice of some of your numerous readers.—(X., in *Scottish Gardener*.)

REDLEAF AND ITS GARDENING.—No. 2.

Fig. 3.—REDLEAF—View of the Rock Garden from the bottom of the Lawn.

THE two engravings given at pages 4 and 5 being the English garden and the view to the westward of the mansion, we now come to another portion of the grounds, and one, perhaps, the most lovely of any,—the Waterfall Rock Garden, which comprises an extensive space; its northern side formed by an irregular face of natural rock, while masses of rock are scattered about in various directions—not little pigmy imitations of rock-work composed of small stones forming artificial-shaped mounds, but large blocks which, individually, might almost be measured by the cubic yard. Groups of these masses present themselves at various points, generally one side of them being concealed by some choice tree or shrub, but enough of the stone is seen to give it the character it is known by, and it would be difficult to conceive a more happy effect than this garden has when seen in bright sunshine. I believe the whole of the stonework is artificial, and yet it shows all the features of having been there from time immemorial. Large stones, partly jutting out of the soil in some places, in others rising to considerable heights, with Heaths, dwarf Rhododendrons, *Pinus Clanbrasilensis*, and other shrubs amongst them; and a mass of *Juniperus repens* I noticed as being upwards of 25 feet in diameter, and might have been 50 feet, but was obliged to be cut. The beautiful

carpety appearance this has, with its soft elastic shoots overlying each other, offering a good example to our manufacturers in the making of plush and similar draperies; and two *Pinus Clanbrasilensis* appeared to be 7 feet through and 5 feet high. *Thuja Doniana* promises to become a pretty and useful Conifer, and is quite hardy. Several Heaths appear to bear cutting as well as Box does in a general way.

A flight of rustic stone steps ascended an eminence in this garden, and a walk of the same material perhaps showed more the assistance it had received from art than anything else, and was the only thing I could find fault with, and, perhaps, in this I might be wrong. Some noble specimens of Coniferæ skirted this garden, and linked it with the more ordinary grounds to the south. I had only an opportunity of ascertaining the dimensions of a few of these trees, but I hope Mr. Cox, the intelligent gardener there, will give us more particulars about them.

Amongst other trees I noticed *Abies morinda*, 37 feet high; *Pinus ponderosa*, 50 feet, a fine tapering tree, more inclined to go upwards than it generally does; *Abies Menzeisi*, 32 feet, very fine; *Pinus radiata*, in the way of *P. insignis*, but of a still more deep green, 12 feet, and very promising; *Pinus*

muricata; Libocedrus chilensis, 7 feet; both the Cephalotaxus Fortunei, male and female, which in foliage and general appearance are much more distinct than many varieties to which distinct specific names are given; some fine Irish Yews and

other trees; and what give a greater contrast to the whole than any other Pinus were two beautiful specimens of a deciduous Cypress called *Clyptostrobus sinensis*. Outside of all these were some good Oaks on the sloping part of the bank facing the west.

Fig. 4.—REDLEAF—View up the Lawn.

Engraving No. 4 presents a view of that portion of the lawn nearest the mansion, and pointing to it. A corner of the house is seen. The grounds here are more open, but not more so than is prudent, considering the good things by which the house is surrounded. Close, well-kept turf, not cut up into tiny flower-beds, nor yet too much intersected with walks, forms the

principal feature. The inclination of the ground to the west and south is allowed to take that form in the more easy and natural way. Some fine shrubs and trees breaking the outline in the westerly direction, while the high trees behind the English garden form a good background to the right, the whole being in excellent keeping.—J. ROBSON.

(To be continued.)

BRITISH FRUITS & POMOLOGICAL GLEANINGS.

ASHMEAD'S KERNEL APPLE.

SYNONYME—*Dr. Ashmead's Kernel.*

WE have received from Messrs. J. C. Wheeler & Son, of Gloucester, a basket of the fruit of this most excellent dessert Apple. It is a sort not generally known, as its cultivation is confined more particularly to the west of England, where it was raised; and it is with the view of giving it the greatest publicity, that we extract from Dr. Hogg's "British Pomology" the figure and description of this truly valuable variety, which is now just coming into use, and will continue at its best up till May and June, if properly preserved.

"Fruit below medium size; round and flattened, but sometimes considerably elongated; the general character, however, is shown in the accompanying figure.

"Skin light greenish-yellow, covered with yellowish-brown russet, and a tinge of brown next the sun.

"Eye small and partially open, placed in a moderately deep basin.

"Stalk short, inserted in a round and deep cavity.

"Flesh yellowish, firm, crisp, juicy, sugary, rich, and highly aromatic.

"A dessert Apple of the very first quality, possessing all the richness of the Nonpareil, but with a more sugary juice. It comes into use in November, but is in greatest perfection from Christmas till May.

"The tree is very hardy, an excellent bearer, and will succeed in situations unfavourable to the Nonpareil, to which its leaves and shoots bear such a similarity, as to justify Mr. Lindley in believing it to be a seedling variety.

"This delightful Apple was raised at Gloucester, about the beginning of the last century, by Dr. Ashmead, an eminent physician of that city. The original tree existed within the last few years in what had originally been Dr. Ashmead's garden, but was destroyed in consequence of the ground being required for building. It stood on the spot now occupied by Clarence Street. It is difficult to ascertain the exact period when it was raised; but the late Mr. Hignell, an eminent orchardist at Tewkesbury, in Gloucestershire, informed me, that the first time he ever saw the fruit of Ashmead's Kernel, was from a tree in the nursery of Mr. Wheeler, of Gloucester, in the year 1796, and that the tree in question had been worked from the original, and was at that time upwards of thirty years old. From this it may be inferred that the original tree had attained some celebrity by the middle of last century. The Ashmead's Kernel has long been a favourite Apple in the gardens of West Gloucestershire, but it does not seem to have been known in other parts of the country. Like the Ribston Pippin, it seems

to have remained long in obscurity, before its value was generally appreciated; it is not even enumerated in the catalogue of the extensive collection which was cultivated by Miller and Sweet, of Bristol, in 1790. I find it was cultivated in the Brompton Park Nursery in 1780, at which time it was received from Mr. Wheeler, nurseryman, of Gloucester, who was author of "The Botanist's and Gardener's Dictionary," published in 1763, and grandfather of Mr. J. Cheslin Wheeler, the present proprietor of the nursery, to whom I am indebted for specimens of the fruit, and much valuable information connected with the varieties cultivated in that district."—H.

ENGLISH RAISINS.—In corroboration of what was said by "R." in last week's JOURNAL OF HORTICULTURE I have read in an American gardening journal an account of a long discussion about preserving Grapes. They seem to do so largely in America, and from what they say, by gathering them late in October, I suppose they use their thick-skinned sorts, Isabella and Catawba, &c., and place the bunches in single layers in paper boxes, holding about 5 lbs. Some people keep them in a dry room, and then place them in a dry airy cellar for the winter. One person said that he kept his Grapes till April, and others said till February and March—no bran with them, as recommended by "R." In their dry climate the cellar would do, but not here, I think. A dry, warm room must be our place. At any rate, reading the above has convinced me that by the simple plan suggested by "R." any family in a Grape-season may have them on their table all winter, and those with vineries need not have the trouble and expense of keeping them on the Vines.—T.

FRUIT FORCING IN THE OLDEN TIME.—Bradley says, writing in 1722, "Mr. John Millet (of North End, Fulham), whom I have so often mentioned on account of ripe Cherries in February, was the chief if not the only gardener in England for bringing his fruit out of season to good ripeness and perfection. I have eaten in February Duke Cherries so ripe that they were almost black, and, in my opinion, were as well tasted as any of the summer growth, which depended on his just management of them, in applying a due heat at proper times."

BOWOOD MUSCAT GRAPE.—This Grape was raised from seed by Mr. John Spencer, of Bowood, and is distinguished from Muscat of Alexandria, of which it is a seminal form, by the plant being very much later in starting into growth, and in setting its fruit more freely than that variety. This peculiarity in vegetating late is not, however, maintained during the whole period of growth, for the fruit is ripe equally as early as that of the Muscat of Alexandria, from which it is generally acknowledged to be distinct. All that has been said about this variety being identical with another sort called "Passe Muscat" must to some extent be imaginary, Passe Muscat being merely a synonyme of Muscat of Alexandria, and regarded as such by all pomologists both in this country and on the continent for the last hundred and fifty years. There can be no doubt but that Bowood Muscat has its own individuality, however similar it may be to any other variety.

ACTION OF FROST ON THE QUALITY OF FRUITS.—A Connecticut friend states that Pears, which usually have an astringent property, are rendered of the highest excellence by a slight exposure to white frost. The Vicar of Winkfield he particularly refers to as being rendered a first-class fruit by this process. We have a neighbour who has a very large Vicar; and it has been a curious subject for speculation with us for some years past, why the fruit on some portions of the tree should be very superior, and on others so absolutely worthless; and we think it quite probable that the hint above noted affords the real reason. The after-treatment of fruit is of quite as much importance as obtaining good kinds, and the note of our friend is worthy of more extended observation. It is well known how frost acts in removing the astringency of the Persimmon; and it is just as likely to have the same effect on the Pear. Many of our second-rate Pears would be really delicious but for a slight puckering flavour. If frost will aid in removing this objection, what a valuable fruit Louise Bonne of Jersey, for instance, would be! Of course, caution will be needed, as too much frost would induce decay.—(Gardener's Monthly).

[This being an extract from an American journal, the remark upon Louise Bonne of Jersey is not applicable to that fruit grown in this country.—Eds. J. of H.]

ENTOMOLOGICAL SOCIETY'S MEETING.

THE Meeting of this Society, held on the 4th March, under the presidency of J. W. Douglas, Esq., was fully attended. The display of new and interesting insects taken during the preceding year, notwithstanding its inclement nature, and the near approach of the ensuing collecting season, was remarkable, proving as it does the unabated ardour with which the science, or rather, perhaps, the collecting of specimens is pursued.

Dr. Knaggs stated, that having forwarded specimens of the Moth (to which he had applied the name of *Nonagria Bondii*), to M. Guenee, the great authority for the nomenclature of European Moths, it had been pronounced a distinct and undescribed species.

Mr. Stainton exhibited a new British Moth belonging to the same family, Noctuidæ—viz., the *Xylina conformis*, of Treitschke, which had been taken on Ivy blossoms, near Cardiff, in October last.

Dr. Wallace exhibited specimens of a Moth belonging to the genus *Lasiocampa*, reared from the caterpillar taken in the Isle of Wight, which closely resembled the supposed species from the north of England, named *L. callunæ*, by Dr. Palmer; also, some fine dark varieties of *Hemerophila abruptaria* and its pupa case found near London.

Mr. Mitford exhibited a curious hybrid Moth reared between *Biston pilosaria* and *hispidaria*; also a fine variety of *B. prodromaria*, and a series of six species of Moths belonging to the curious genus *Fumea* (commonly called chimney sweepers from their small size and black colour), which he had reared from the caterpillars, which inhabit moveable cases, taken at Hampstead, one of which appeared to be undescribed.

Mr. G. R. Waterhouse continued his critical observations on the species of minute British Coleoptera, on which he has been for many years engaged. He exhibited a fine specimen of *Anobium denticolle*, taken in the neighbourhood of London, and read descriptions of new and rare species of the genera *Scymnus*, *Clambus*, and *Bryaxis*.

A paper was read by Mr. Kirby on the geographical distribution of the beautiful Moths forming the family *Zygenidæ*. The majority of these insects are natives of the warmer regions of the earth.

A monograph on the genus *Pronophila*, belonging to the family of Butterflies, *Hipparchiidae*, by Mr. Hewitson, was read. The species are natives of equatorial America, and bear a close resemblance to our meadow-brown Butterflies.

A paper containing descriptions of new species of *Aculeate Hymenoptera*, taken at Panama, by Mr. Stretch, was also read by Mr. F. Smith.

ROSES AND THE SEVERE WINTER.—The sensible suggestion in a recent number of THE COTTAGE GARDENER that the sad destruction of Roses through the late frost should lead to their cultivation upon their own roots is singularly confirmed in my own case. Whilst Lamarque, Safrano, *et hoc genus omne* have been swept away, a delicate Tea-scented Rose, which I usually remove for the winter to the greenhouse, has stood the severe frost out of doors, and though it has died back within a few inches of the ground it is making good shoots; it grows from its own roots.—BRUTONIENSIS.

REPORT ON THE GARDEN PEAS.

GROWN AT CHISWICK DURING 1860.

By ROBERT HOGG, LL.D., F.R.H.S., Secretary to the Fruit Committee.

22. November Prolific.....NUTTING & SONS.

The plant is 2 feet high, with dark green foliage. The stem is rather robust, generally simple, but occasionally branched, and bears from twelve to sixteen pods. The pods are generally in pairs, rather short, and contain from four to six Peas in each. Ripe seed white, medium-sized, smooth, and compressed.

Sown February 19th; bloomed June 16th; slatted June 28th; and the pods ready to be gathered July 11th.

This somewhat resembles in growth the *Royal Dwarf*, but is very inferior to that variety; and, in fact, is not worth growing for any purpose.

23. Egg.....NOBLE, COOPER, & BOLTON.

This is a very old variety, and long known by the name of

Black-eyed Susan from the seed having a black hilum or eye. The plant is of a strong and robust branching habit of growth, and from 7 to 8 feet high. It produces about eighteen pods, which are almost always in pairs, and these contain about seven good-sized Peas, which are large and oval like a horse Bean. Ripe seed white, large, egg-shaped, and with a black hilum.

Sown February 19th; bloomed June 20th; slatted July 18th; and the pods were ready to be gathered July 12th.

This, though an abundant bearer, is quite a worthless variety, and it would be difficult to say for what object it is cultivated. The Peas have a very thick skin, and a coarse bean-like flavour, and when cooked are generally of a dusky brown colour.

24. Victoria Marrow.....NOBLE, COOPER, & BOLTON.

SYN. *Gibbs' Defiance*GIBBS & CO.

This is also known by the names of *Waterloo Marrow*, *Giant Marrow*, *Wellington*, *Royal Victoria*, and *Tall Marrow*.

The plant is of a strong and vigorous habit of growth, having a simple stem from 6 to 7 feet high. The pods are produced near the top of the stem, sometimes single, sometimes in pairs in about equal proportion, and contain from five to seven very large Peas. Ripe seed white, large, uneven, and roundish.

Sown February 19th; bloomed June 18th; slatted June 26th; and fit for use July 13th.

25. Princess Royal.....TURNER.

The plant is 3 feet high, a strong and vigorous grower, with dark green foliage. The stem is generally simple, but occasionally branched, bearing from ten to twelve pods, which are usually in pairs. The pods are large, and have an attractive appearance, but they fill slowly and indifferently: so much so that when opened they average only from three to six large Peas in each. Ripe seed large, round, uneven, and white.

Sown February 19th; bloomed June 12th; slatted June 26th; ready for use July 20th.

This variety seemed to have suffered from the cold summer, the pods having a chilled and starved appearance; and it is, therefore, not improbable but that in a warm season it may prove a useful and prolific late Marrow.

III. GREEN MARROW PEAS.

Ripe seed of a mixed white and olive colour, either small, round, and pitted, or large, irregular, and uneven. Foliage dark green and blotched. Pods dark bluish-green, very glaucous.

26. Prizetaker.....NOBLE, COOPER, & BOLTON.

SYN. *Prizetaker Green Marrow* SUTTON & SONS.

Rising Sun.....TURNER.

Leicester DefianceBECK & CO.

The plant is 4½ feet to 5 feet high, of a vigorous habit of growth. The stem is sometimes simple and sometimes branched, and produces from twelve to eighteen pods. The pods are in pairs, very rarely single, and of a deep bluish-green colour, covered with a thick and distinct bloom; they contain six to seven large Peas in each, which are of a dark bluish-green. The ripe seed is small, round, and of a mixed white and green colour.

Sown February 19th; bloomed June 5th; slatted June 20th; ready for use July 6th.

This is a very excellent Pea, and an abundant bearer; but I cannot perceive any great difference between it and Bellamy's Early Green Marrow, which I grew in a collection for the purpose of comparison in 1853, and a very excellent form of which was grown by Messrs. Noble, Cooper, & Bolton, under the name of Noble's Early Green Marrow. In that year the latter was sown as late as the 5th of April; bloomed on the 15th of June; slatted on the 21st; and on the 8th of July the crop was ready for use.

27. Early Green Marrow NOBLE, COOPER, & BOLTON.

SYN. *Dwarf Green Marrow*...HURST & M'MULLEN.

This bears considerable resemblance to the preceding, with the exception of having a smaller pod, and being about five days later in coming into use. It also grows about 7 feet high, and is in every respect an inferior variety to it.

(To be continued.)

TRADE CATALOGUES RECEIVED.

Catalogue No. IX.—Stove and Greenhouse Plants, by Peter Lawson & Son, Edinburgh, London, and Hull.—This is in Messrs. Lawsons' usual 4to form, closely printed, and extending

over thirty-eight pages. It is arranged into—1, Greenhouse Plants; 2, Ferns; and 3, Stove Plants, or plants cultivated under glass with heat. The first is divided into—1, Plants cultivated under glass in winter, and out-doors in summer; 2, Selection of greenhouse climbing plants; 3, Epacris; 4, Cape Heaths; 5, Indian and Chinese Azaleas; 6, Camellia japonica. The second division is arranged in—1, Greenhouse and Stove Ferns; 2, Hardy Exotic Ferns; and 3, Hardy British Ferns. The Stove Plants are divided into—1, Selection of Stove Plants; and 2, Stove Climbing Plants. We need hardly say this catalogue is an excellent one.

List of Plants of the Fir suitable for the climate of Great Britain, cultivated at St. John's, by Richard Smith, Nurseryman and Seed Merchant, Worcester.—In this catalogue we have before us a book prepared with great skill and pains, which serves the purpose not only of a priced catalogue, but a reference for useful information on every subject which it contains. It extends over seventy-six pages, and is in the 4to form. The collection of Conifers it records is an extensive and a valuable one.

A Descriptive Catalogue of Chrysanthemums, Dahlias, &c., grown for sale by William Holmes, Well Street, Hackney, N.E., contains the names of everything worth having, and good descriptions of them. We have also before us Mr. Holmes' *Catalogue of Garden, Agricultural, and Flower Seeds*, of which the same may be said.

Catalogue of Agricultural, Kitchen-garden and Flower Seeds, sold by Edward Taylor, Malton, is a copious catalogue and well got up.

Descriptive Catalogue of Seeds for the Farm, the Kitchen Garden, and the Flower Garden, by John A. Bruce, Hamilton, Canada West.—This is a meritorious production, a worthy scion of a noble family, which might raise a blush on the cheek of its elder brethren. Some of our provincial and metropolitan houses, too, might take a lesson from their Canadian cousin.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the season for applying manure in a liquid state to kitchen-garden crops is approaching, it is advisable to provide a tank, a barrel, or any other sort of receptacle in the dungyard, or frame-ground, for receiving all the drainings of hotbeds, heaps of fermenting dung, &c. Such liquid manure produces a most beneficial effect on all crops when applied during their growing season. After the late rains it will be advisable to pass a heavy roller over the gravel walks to set and bind them well for the season. Trench up all spare ground, placing all green refuse at the bottom of the trench. Take every opportunity to destroy slugs which the recent rains have brought out from their winter quarters in abundance, an application (to be repeated), of quick lime on a warm evening after a showery day, is a well-known remedy. *Basil*, sow in pans or on a slight hotbed, and afterwards plant it out. *Beans*, earth up the early crops, but before doing so lay a little soot close to the stems; timely earthing will also prevent the wind damaging them. *Broccoli*, make a sowing of most of the varieties. By sowing early there is time for a second sowing in case of failure. *Carrots*, thin out those sown in frames, and give them a liberal supply of water when dry. *Kidney Beans*, a sowing may be made on a warm, sheltered border where the soil is favourable to early crops, and a sowing may be made in pots for planting out as soon as all danger from frost is over. *Lettuce*, loosen the soil about those planted in the open ground and save them from slugs. *Onions*, sow the Silver-skinned on a poor, dry piece of ground to produce picklers. *Sea-kale*, remove the covering immediately it is done with. If there is any yet remaining to be covered, let it be done before it grows much. *Turnips*, thin out those in frames, and give them water when necessary. Take every opportunity for eradicating weeds; hand-weed where practicable as it more effectually answers the purpose than hoeing and raking where the soil is moist.

FLOWER GARDEN.

Now is the time to come to some final arrangement as to the colours for the beds and borders, that a calculation as nearly as possible may be made of the number of plants that will be required for each bed and border. The *Mimulus* family may soon be transplanted in fresh patches in moist soil and situation, not forgetting that popular favourite the Musk, which should be planted in large patches. See that *Narcissi* and *Fritillarias* are

staked and tied in good time. Proceed with the planting of hardy climbers against walls, trellises, and verandahs, selecting some of the most showy species of *Caprifolium*, *Clematis*, *Wistaria*, *Bignonia*, with some of the strong-growing *Noisette*, evergreen, and Hybrid climbing *Roses*. Sow, if not already done, patches of some of the most showy of the hardy annuals in vacant places that are usually to be found in the herbaceous beds, and in the edges of clumps and borders in the shrubbery. The following are suitable for the purpose—Double Poppies of various colours, African and French Marigolds, the new Sunflower, white and purple Candytufts, *Clarkia*, *Collinsia*, *Nemophila*, not forgetting the old and general favourite, *Mignonette*. If Carnations are at hand, by planting these in a group they produce a bold and striking effect.

FRUIT GARDEN.

The bloom of the choice kinds of Pears against walls to have some protection when frost occurs. Top-dress Raspberries, and let them be well staked.

STOVE.

A succession of *Achimenes* intended to flower late in the autumn to be placed in heat. Pans or broad shallow pots are best for their general cultivation, and as they require an abundant supply of water when in bloom, the drainage should be very perfect to admit of it without stagnating the soil. Orchids will require an increased humidity as the increasing power of the sun will induce a more rapid evaporation; an efficient shading material to be in readiness for use when wanted. Proceed with the potting when necessary, and the general regulation of the plants. Shut up a solar heat, if possible, of 80° towards three or four o'clock.

GREENHOUSE AND CONSERVATORY.

Proceed with the staking and tying-out of plants requiring such assistance. Turn each plant frequently round that it may not become one-sided. Where hardy shrubs are annually forced select the most suitable when removed from the conservatory, and give them some kind of shelter to harden gradually their foliage. From having been previously forced these will bloom earlier than new stock of which a portion should each year be potted to replace such as become useless for further work. Heaths, Epacris, and other hard-wooded plants to be potted as they require it. The most suitable time is after they have done blooming and have commenced a new growth, care to be taken before potting that the whole ball is thoroughly moist, for if potted in a dry state it will be impossible afterwards to moisten it properly without saturating and souring the new soil. Look well after the Azaleas for next year's blooming. Use heat liberally to get their growth forward, and if any shoots become too luxuriant pinch the tops off. Select from the winter stock some strong well-shaped plants of Scarlet Geraniums, Fuchsias, Petunias, &c., to form large specimens for vases, and for planting out singly on the lawn or in other conspicuous situations. Give them their final shift and stake the shoots well out.

PITS AND FRAMES.

These will require daily attention: propagating, pricking off, hardening off, &c., to be continued for three weeks or a month longer, by which time a liberal supply of stock should be provided for all necessary purposes. Attend to covering at night when there is an appearance of frost; to giving abundant supplies of air during the day, and to watering in the morning. The Chrysanthemums when well rooted to be potted off singly into small pots; when they have made fresh growth to be stopped back to three eyes, which should be continued as they progress in growth until the beginning of July, to produce fine, dwarf, sturdy plants. Remove Scarlet Geraniums, Calceolarias, Verbenas, Petunias, &c., to a cold frame that a hardy habit may be induced preparatory to being planted out. The Lilliums now in pits to receive a liberal supply of water, and to be neatly staked. Give them a top dressing of turfy peat, sand, and well-decomposed cowdung.

W. KEANE.

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

INITIAL LETTERS (*Rosa*).—Thank you for your suggestion. It is our intention to commence each Number with a pictorial initial letter, and we shall be glad to accept of and publish any pretty designs you or any other of our readers may send us. Of course we shall not engrave them unless they are approved.

HARDY ANNUALS FOR EXHIBITION (*Mene incepto, &c.*).—There are not so many as twelve first-class annuals for competition. *Nemophila*, *insignis* and *maculata*, six plants of each to choose from. *Linum grandiflorum*, commonly called *rubrum*, six plants to pick the best for the show. *Lobelia erinus speciosa*, the best pot plant of all the annuals, although not strictly classed with annuals. *Lobelia bicolor, rosea*, or *Lindleyana*, a true annual, and, like the last, one of the best pot plants among them. *Tropæolum majus*, *Scarlet Gem*, a little improvement on the common colour of *Tom Thumb Tropæolum*. *Viscaria oculata nana*; if you can get it warranted true from a next-door dealer, send not a distance for it: it is a beautiful pot plant, with more and better purple than the original. *Dianthus Heldewigii* and *lacinia*, several plants of each in order to choose from, there being great diversity of tints. *Hummelmannia fumarifolia*: some people recommend this for pots, and we mention it to say it is the very worst of all the annuals; it went out of cultivation in 1823, when *Eschscholtzia* came in its place, and it should never have been revived again. *Eucharidium grandiflorum* and *roseum* make pretty gay pot plants. *Collinsia bicolor*, much in the same style as the last. *Gilia tricolor*, the same looks and value as the two last. These are all that we can think at all fit for pots; but no hardy annual is fit for pots, save to keep over the winter and help to keep a greenhouse gay in the spring, and for doing that none of this selection is good save the last two.—D. B.

ANTS IN A HOTHOUSE (*E. D.*).—Sprinkling guano about their haunts, and watering with ammoniacal liquor from the gas works, will drive them away. Repeat the application if the first is not effectual.

SOWING HALF-HARDY ANNUALS IN A WALTONIAN-CASE (*A Subscriber*).—They should be sown in pots, and all other seeds the same way for that way of raising them. The length of time the seedlings should remain in the case no one can tell, as no two kinds are alike exactly on that point, and every week from the 1st of March to the 10th of May makes another difference as to the length of time the seedlings should remain in the case. All the management required for a Waltonian-case is exactly the same as would be needed in a Cucumber-bed, or a bed made for cuttings and seeds in the spring, and nothing more or less, the only difference being in the mode of getting bottom heat. Now when seedlings are in too hot a place, or are too much confined, they "draw" or get spindly; to prevent which, move them to a cooler place. As the heat for warming the air of all Waltonian-cases must come from the bottom of the case, the bottom part must never be covered with mould to plant in.

CINERARIA (*Bowman*).—Yorl Cineraria has not sufficient character about it. The flower is not large enough, and there is nothing new in the colour.

SPORT FROM FLOWER OF THE DAY (*D. C.*).—Keep the one plant two or three years to see if it will sport farther; at present it is not worth increasing.

ROSES FOR A SOUTH WALL (*Idem*).—We have very great objections to having Roses on the south or south-west sides of dwelling-houses. Such places are by far too dry and too hot for Roses, and the consequence soon is, all kinds of insects and all sorts of nasty remedies to get rid of them. The summer of 1860 was the best summer for Roses in the memory of man—very cool and very moist it was, and that the best Roses like. But how is a Rose against a south wall in a midland county to get a very cool and a very moist climate? or how is it to be kept free from insects and from liquid manure? By drawing drills, as for peas, along a border for Roses in front of the parlour window, and by filling these drills the instant, though the strongest liquid is applied, there is no fear from the fumes. If Roses against the south wall of a house had a dose like that once in ten days, from the middle of May to the end of August, and no more the year round, there would be little to do against insects than what the garden engine filled from the pond could accomplish, and with such strong-growing Roses as the following there would be the least risk and trouble:—*Jules Margottin*, *Lord Raglan*, *Auguste Mie*, *Baronne Prevost*, *Alexandrine Bachmetoff*, *Général Jacqueminot*, which are among the very best of the very free-growing Roses; and if they were on their own roots, or if worked very low on the Dog Rose, or on properly prepared stocks of *Manetti*, they would do second best on very strong land on the Dog Rose, or on very poor land if it suited *Manetti*—not otherwise. But after all is said, all strong Hybrid Perpetuals are never so free from insects as when they are once well established on their own free-willing roots, and we would not plant worked Roses against a house for any consideration.

MUSE MINULUS (*J. F.*).—The Musk Minulus comes from seeds exactly like the little blue *Lobelia*s, and they, the seedlings, do best by the same treatment as is given to these blue *Lobelia*s till they are planted out in May. Musk Minulus will also sow itself in the open ground and come up thick as grass; it will also do to be sown thin as *Mignonette* where it is to grow. It is not the first that always kills it. We know a large bed of it which stood the frost of 1838, and 1841, and every frost since to this day without a particle of shelter, but we ourselves lost it repeatedly out of doors when they were little frost. Some people are not aware that Musk Minulus grows four times faster and stronger in peat than in any kind of loam. We once thought we lost a bed of large half-guinea plants of the Ghent Azalea by this very Minulus. Both came into fashion between 1828 and 1832, and it was in the latter season that we had to send mowers to clear off the Musk in large green hay-like bundles.

GLADIOLI FOR A SMALL GARDEN, AND FOR POTS (*An Old Friend*).—Any will grow in the open garden, and therefore regulate your choice by their colour and price. No one kind is better than another for pots, and the "roots" which are now worth 7s. 6d. a-piece, are not one whit more gay at two yards' distance than *Brenchleyensis*, which should be among the cheapest: therefore Gladioli in pots, or Gladioli in beds, is only a question of the purse. Every one of them is just as well suited for pots as any one you could choose, and every one of them is just as well suited for a bed as any other. Kinds and newness make all the difference in price.

PEARS NOT KEEPING (*Idem*).—All the varieties you mention and many others have decayed prematurely in the past winter and spring now passing. There is scarcely a Pear to be had in Covent Garden Market.

VINES INTERFERING WITH SASHES. (—) Nothing would induce us to rub off the bands from the Vine-rods merely to enable the sashes to open. It would be sacrificing too much of the crop. We should adopt means to put the stems out of the way of the sashes, or have these to open in some way not to interfere with the Vines. We cannot make any more particular suggestion, as we do not know how the sashes open.

RESTORING POTASH TO SOIL. (L. D. W.).—There can be no great difficulty in restoring cheaply to a soil the potash taken from it by a crop of Potatoes. Burn the haulm, and sow its ashes over the ground. That will return the potash it derived from the soil. The tubers do not contain more than half a pound per cent. of potash; so that if you have 25 tons of them from an acre, you need only sow over that acre 2½ cwt. of potash, which would be no great expense. No apology needed to Mr. Jones. We are glad that you think his information is useful.

LAURELS AND HOLLY KILLED BY THE WINTER. (B. W.).—Cut them close to the ground now. Prune your weakly Hollies as soon as you see their first young leaves this month or early in May. The pyramidal Hollies which have shed their leaves are probably killed, but leave them, and plant some climber, as *Felicité Perpetuelle* Rose, to cover their branches.

DWARF CARNATION. (L. T. P.).—We have seen seedling Carnations of various heights, but never any so dwarf as you mention (3 inches). As you do not say whether the habit is healthy, though dwarf, (for it may be the result of disease), or what the character of the flower is, it is impossible to say whether it would be of any value or not, even as an ornamental flower.

GLASS FOR CUCUMBER-HOUSE. (J. Errington).—We should use rough plate glass for the roof, and clear glass for the side and ends. That at 23s. per 100 feet would do very well.

BEDDING. (Gemmato).—If you buy our No. 20, you will find at page 225 full directions and illustrative drawings.

CHARCOAL STOVE IN GREENHOUSE. (A Constant Reader).—Unless the stove has a chimney to carry off the fumes (carbonic acid gas) arising from the burning charcoal, it will be under any circumstances liable to injure the plants; and if you shut up the greenhouse with a chimneyless stove, burning charcoal in it, the plants will be for the most part destroyed.

NUMBER OF PLANTS FOR A VERBENA-BED. (Jack of all Trades).—A Verbena-bed 24 feet long and 5 feet wide, will need about twelve dozen of the very best plants you can buy, or, say five rows and thirty plants in a row, or about 9 inches apart every way. Look over the Verbena-beds and the kinds we reported and criticised for the last two or three years, choose the kinds of Verbenas, and send us a plan of the way you have proposed to plant them. Send the plan to us and we shall have pleasure in pointing out to you if there are any faults in it, and how best to mend them; also, perhaps, suggest an entire alteration which would improve your own idea altogether—not our own idea, for we never give it that way.

NAMES OF PLANTS. (M. F.).—You are quite unreasonable in sending twenty plants for names at one time, and we must make it a rule to decline to receive more than five or six from any one correspondent at a time in future. Nos. 1 to 7, and No. 14, are garden varieties of *Euphrasia*, which we cannot attempt to name; 8, *Leschenaultia formosa*; 9, *Gnida pinifolia*; 10, *Eriostemon myoporoides*; 13, *Euphrasia grandiflora*; 18, *Pittosporum Tobira*; 20, *Acacia cynarum*. (A Constant Reader).—It is *Phlomis fruticosa*, or Jerusalem Sage.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

MAY 21st, 22nd, and 23rd. CHESTERFIELD AND SCARSDALE. Hon. Sec., Mr. Thos. P. Wood, jun., Boythorpe House, near Chesterfield. Entries close May 1st.

MAY 22nd and 23rd. BEVERLEY. Hon. Sec., H. Adams. Entries close May 4th.

JUNE 4th, 5th, 6th, and 7th. BATH AND WEST OF ENGLAND. Steward, S. Pitman, Esq. Entries close May 1st.

JUNE 19th, 20th, and 21st. COALBROOKDALE. Secs., J. B. Chune, and Henry Boycroft, Coalbrookdale.

JUNE 28th. DUFFIELD. Sec., Mr. R. Davison. Entries close June 22nd.

JUNE 28th and 29th. TAUNTON. Sec., Mr. Charles Ballance. Entries close June 14th.

JULY 2nd and 3rd. BLACKPOOL. Sec., Mr. E. Fowler, jun.

SEPTEMBER 3rd. POCKINGTON (Yorkshire). Sec., Mr. Thomas Grant. Entries close August 26th.

DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. Sec., M. J. B. Lythall, 14, Temple Street. Entries close November 1st.

N.B.—Secretaries will oblige us by sending early copies of their lists.

CURRENT EVENTS.

OUR Silver Pheasants laid the first egg Tuesday, March 26th. One has laid every other day, always between half-past five and six in the evening. We have been anxious to give all the information we can to the correspondents who have asked for it, and believing they will have put their birds in some such places as we have described, we will advise them to look well after the eggs. The hens will not always lay in the same place, but for an hour or two before laying they will be seen to hollow out places in the gravel, removing all the large stones. They should be watched then, as the cocks especially are guilty of chipping and eating the eggs. They sometimes leave off laying for a few days and begin again, and if the eggs are taken away they lay two sittings in the season, the second after a short interval. As in all other cases, the fresher the eggs are when put under the hen the better it is, for we have strong belief that has an influence

on the produce; but if a trusty hen cannot be found at the time, the eggs are not spoiled by being kept a fortnight or three weeks. The proof of this is, that a Partridge will lay nineteen, or a Pheasant seventeen. This will occupy three weeks or more, and, of course, some of the eggs must have been laid the full time, they, nevertheless, hatch all. There are rare instances of a Golden or Silver hen hatching and rearing poults, but it is seldom the case. A middle-sized hen, a half-bred Game, is the best for the Silver eggs, she will cover fifteen; but for Golden, a Bantam is better, as they are smaller and their shells are not so hard.

Californian Quails are laying. These are very beautiful birds, bold, cheerful, and familiar. They are free layers. The eggs should be put under a Bantam, and there is no better place wherein to rear the young than an empty cucumber-frame, the young do well in it. It is essential to supply these birds freely with green food at this time of the year, they cannot do without it, and the hens often die for lack of it.

Common tame Pheasants will soon be laying; some few eggs may be laid already, but that is not what we mean by laying, as they will not make a nest. We remind all to make a partial covering over a slight hollow which must be filled with sand or dust. They will drop their eggs in it, and there will be no danger of their being starved or spoiled. The bough of a fir tree, or a havin, will supply all the shelter that is necessary.

During a rapid poultry tour of three or four days at Easter, we have seen some of our best breeding-places, and some of our best birds. We find everywhere there is a dearth of broody hens, and, consequently, we saw but few very young chickens. We saw many that were hatched in the early part of January; but we think we never saw so few February chickens in our lives. The birds had not laid during the hard frost of the early part of the year, and they suffered so much from the severity of the winter, that it took the first fortnight of the milder weather to recover themselves. Many yards that will swarm in a week have nothing to show at present save a few very early birds.

We fancy our summer shows will bring some very good and early chickens, but they will be few in numbers compared with later-hatched ones. Wherever we went we heard the same, that "the oldest inhabitant" never recollected a winter during which birds suffered so much. We have seen a great many Spanish and Cochins which we should fear would be disqualified from the extraordinary appearance of their combs. Some have lost the front, some the back, and some have lost the middle, while in places all have lost their toes. Thank goodness, we can speak of it as past, and if the present mild weather lasts we may look for rapid growth in the chickens, that will now come out daily by hundreds. We must, however, warn our readers not to be tempted to let their hens with chickens run at liberty because there is a little sunshine. Still choose sheltered spots; let the hen be under her rip day and night, and feed generously. If the wind shift to the east, see that your broods are not exposed to it, and under any circumstances do not spare the bread and ale. The chickens should have it three or four times per day.

BANTAMS WITH INFLAMED OVARY AND EGG-PASSAGE.

I HAVE some white Game Bantams, three of which seem perfectly healthy, except on the day they lay, and then they have a very sickly look about the head and scarcely can move. They then refuse food, but drink as much water as they can get; and if I put my hand under the crop and incline the head a little downwards, about half a gill of water will run out of their mouths: they continue so till they lay. The eggs have thick skins on and no shells; after laying them they generally pass a good deal of lime mixed with blood, and seem in great pain. They have the range of large fields, and have a warm, clean, and good roost. I have got seven white hens and two cocks; three of the hens lay these eggs, three have not began to lay at all yet, and one lays good eggs. I have some Brown Red Bantams as well, but they have not begun to lay yet. I have a good lot of Game fowls and Cinnamon Cochins that lay very well indeed; their chief food is Indian corn, and occasionally, a little barley.—THOMAS RADCLIFFE.

[Your Bantams are suffering from inflammation of their ovaries and egg-passages, occasioned probably by over-feeding. Indian corn is very fattening, and excess of fat is the source of a

majority of the disorders which afflict hens. Give the Bantam hens a dessert-spoonful of castor oil, and repeat it each third day until they cease laying shellless eggs, and voiding bloody excrements. Do not feed them with any Indian corn; substitute oats for the barley, give very little even of them; but feed chiefly on soft food, and but little of that. Your other Bantams may be treated in the same way; they do not lay, probably, because over-fat.]

BLACK ROT IN SPANISH FOWLS.

I HAVE been obliged to kill many of my Spanish fowls on account of a disease which comes in the comb, making it turn purple; their feet also swell, they become very lame, and their toes rot off. What is this disease, the cause, and the cure? — A CONSTANT READER.

[Spanish fowls are different from others with respect to their diseases. They are not subject to roup, nor do they catch it from contact with the most virulent cases. By way of compensation they have what is called the "black rot" among old breeders. This affects them in many ways, but always with general wasting, black combs, and swollen legs and feet. The treatment is free—almost constant purging with castor oil, and equally liberal use of stimulants, such as old strong ale, wine, and even diluted spirits. Taken in the early stage this seldom fails to cure, but it is a long process and only worth following with a valuable bird.]

SUNDERLAND POULTRY SHOW.

(From a Correspondent.)

THE county of Durham has just added another show to the list of exhibitions. That at Darlington has, by progressive improvement, attained the position of a first-class exhibition, and the one just held at Sunderland has made a good commencement. Monday and Tuesday, the 1st and 2nd inst., were the days selected for the Show—an arrangement which perhaps injuriously affected the number of entries, from the necessity of sending off the birds of distant exhibitors on the previous Saturday, and thus occasioning a longer absence than many exhibitors would like at this season of the year. Notwithstanding, in nearly all the classes the different varieties of fowls were well represented, and in the prize list appended to this report will be found names which are generally associated with first-class birds. It may be a satisfaction to exhibitors to be informed that their birds were liberally fed, and carefully attended to during the time of the Exhibition.

The Judges were—for Poultry, Mr. J. H. Smith, Skelton Grange, near York; and for Pigeons and Rabbits, Mr. Kinton, Sunderland. The following is a list of the awards:—

SPANISH.—First, E. Brown, Sheffield. Second, J. S. Nicholson, Sunderland. Highly Commended, F. Simpson, West Boldon.

GAME (Black-breasted and other Reds).—First, H. M. Julian, Beverley. Second, R. Tate, Driffield.

GAME (Any other variety).—First, G. W. Langdale, Leekonfield Park. Second, R. Tate. Commended, A. J. Dodds, Halifax; T. Cleminson, Darlington.

DORKINGS (Coloured).—First, S. Burn, Whitby. Second, F. Key, Beverley. Highly Commended, T. W. Hill, Heywood, near Manchester; J. Graham, Newcastle; S. Burn.

DORKINGS (White).—First, S. Burn. Second, T. Younger, Monkwearmouth.

COCHIN CHINA (Buff and Cinnamon).—First, H. Bates, Edgbaston, near Birmingham. Second, W. Dawson, Mirfield. Highly Commended, Mrs. Aglionby, Wigton Hall.

COCHIN-CHINA (Any other variety).—First, T. Stretch, Bootle, near Liverpool. Second, Mrs. Aglionby. Highly Commended, W. Copple, Ecclestone, near Prescot; W. Dawson.

HAMBURGERS (Golden-pencilled).—First, S. Smith, Halifax. Second, R. Tulip, Monkwearmouth. Highly Commended, H. Beldon, Bradford. Commended, J. Shorthose, Newcastle.

HAMBURGERS (Silver-pencilled).—First, J. Dixon, Bradford. Second, H. Beldon.

HAMBURGERS (Golden-spangled).—First, T. Thompson, Wideopen, Northumberland. Second, R. Tate. Highly Commended, J. Dixon; W. Charlton, Newcastle.

HAMBURGERS (Silver-spangled).—First, J. Dixon. Second, H. Beldon. **POLISH (Black).**—First, J. Dixon. Second, T. Leonard, Fulwell. Commended, Messrs. Johnson and Brown.

POLISH (Golden).—First, F. Hardy, Bradford. Second, J. Dixon. Commended, C. Vaux, Sunderland.

POLISH (Silver).—First, F. Hardy. Second, T. Dixon.

ANY OTHER DISTINCT BREEN.—First, J. Dixon. Second, S. Spraggon, Monkwearmouth. Commended, J. Crosland; R. Tate; W. Dawson.

BANTAMS (Game).—First, J. Shorthose. Second, J. Crosland, Wakefield. Commended, H. Ellis.

BANTAMS (Gold and Silver-laced).—First and Second, T. W. Hill, Manchester. Commended H. Marshall, Durham.

BANTAMS (Any other variety).—First, J. Crosland. Second, J. Bayles, Northallerton. Commended, E. Hudson.

SWEETSTAKES FOR GAME COCKS.—First, H. M. Julian. Second, I. G. Park, Whitehaven. Third, H. F. Dodds. Commended, R. Tate.

SWEETSTAKES FOR GAME BANTAM COCKS.—First and Second, R. Moon, Wavertree. Third, G. Allen, Sunderland. (The class commended.)

DUCKS (Aylesbury).—First, T. W. Hill. Second, S. Burn. Highly Commended, R. Tate; R. Abbs; J. W. Sommer.

DUCKS (Rouen).—Prize, R. Tate. (No second.)

PIGEONS.—Almond Tumblers.—First, C. Vaux, Sunderland. Second, E. A. Hargrove, Handsworth, Birmingham. Other variety of Tumblers.—

First, C. Vaux. Second, J. Crawford, Sunderland. **Carriers.**—First and Second, J. Shorthose, Newcastle. **Barbs.**—First, J. Vaux, Durham.

Second, H. Beldon, Bradford. **Pouters or Croppers.**—First, T. Coundon, Sunderland. Second, J. Morrell, Sunderland. **Trumpeters.**—First, T. Coundon.

Second, J. Vaux. **Fantails.**—First, T. Ellington, Woodmansey, near Beverley. Second, F. Key, Beverley. **Jacobins.**—First, T. Ellington.

Second, G. Proctor, jun., Durham. **Nuns.**—First and Second, J. W. Edge, Ashton New Town, Birmingham. **Turbits.**—First, J. W. Lawson, Beverley. Second, E. A. Hargrove. **Owls.**—First, J. Bell, Newcastle.

Second, J. Vaux. Any other distinct breed.—First, C. Vaux. Second, J. W. Edge.

RABBITS.—Lop ears.—First, E. Brooke, jun., Huddersfield. Second, J. Stokoe, Houghton-le-Spring. Any variety.—First, D. Hume, West Hartlepool (Himalaya). Second, Mr. G. Walker, St. Helen's, Auckland.

DORKINGS TOO LARGE TO EXHIBIT.

IN my own opinion Dorkings cannot be too large for exhibition, provided they are well matched for colour, size, shape and form. Now, for rearing fowls for table you do not require large, boney-framed fowls. The young fowls when twelve or fourteen weeks old, if from the produce of these giants, at that age in the summer ought to be fit for the table, but instead of being fit for table there is nothing but frame and bone; but if bred from fair average-sized fowls there would be something far better than a mere frame. Chickens will not carry flesh when young if bred from this large-framed sort. There is a sort commonly known by the name of the Dunghill, in Sussex, which is more prolific for breeding and rearing for table. These fowls I believe to be a cross between the Dorking and the Dunghill, the latter being used in common as a name.

I believe a remark was made in THE COTTAGE GARDENER some few weeks back, that Dorkings could not be too large for table. This I most decidedly believe to be wrong. As I have been a breeder of these giants for exhibition (occasionally), for years, and also fowls for table, I can speak from my own experience. No Dorkings, I am sure, will ever get too fat by running in a farm-yard and moderately fed; but when they are kept and fattened for the occasion, as prize pigs are for the Christmas Shows, I am not surprised to hear the remark, that Mr. Douglas gets his Dorkings too fat, which causes them to have a very sleepy appearance. Poultry may be kept up in good condition without excessive feeding. It is very rare you see now-a-days a pen of prize Dorking chickens purchased at large Shows—viz., at Birmingham and the Crystal Palace, where there are great contests for the championship, which, when they arrive at adult age turn out anything like what the purchaser anticipated at the time of purchase. They are forced so when young, that when they arrive at the age of maturity they are quite worn out, and become useless to any one wishing to breed good stock.

However, Can Dorkings be too large to exhibit? is the question, and I quite agree with the Editors, that Dorkings cannot be too large; but I do not agree in opinion that the giants of Dorkings are so well for the table when young as the above-mentioned sort. I believe mere weight is a very bad thing to try to obtain in Dorkings, and a good, healthy, fair-conditioned bird is by far more valuable for breeding from than an excessively fat one, the chickens from which are generally of a weakly nature.—ONE WHO HAS NOT LOST SIGHT OF A DORKING FOWL.

TUMOUR ON A FOWL'S BREAST.

WHAT is to be done for a Dorking cock which has a kind of tumour just on the point of the breast-bone in front? He is a fine bird of last year. The tumour is about the size of a florin, flat, and much inflamed. There is a crust upon it, which, when picked off in pieces, leaves a raw place under it. He is much reduced in weight, and appears inclined to go rousy from weakness.—E. C.

[The origin of the tumour, probably, has been that the bird has flown down from a height, and, falling on the point of the breast, the skin has been broken, and the introduction of dirt and gravel at the time or afterwards has caused the irritation.

An incision should be made in the skin with a very sharp

knife, the tumour entirely removed, especially any little parts adhering to the bone. The wound should be well washed with cold water, and then sewed up. In sewing, the edges of the skin only must be brought together. If it is attempted to sew it up tight, it causes such discomfort that the bird will not allow it to heal.]

HENS EATING EGGS—SWANS HATCHING.

My poultry-woman informed me just now that some beautiful Grey Dorkings have been detected, when other hens have left their nests, deliberately walking up to them and eating the eggs. Is there any remedy short of death for such disgraceful conduct? I hope there is, as the hens cost me a "mint" of money.

In reply to "J. T.," I beg to inform him that four years ago a pair of cygnets were given to me. Last spring the female produced seven eggs, and hatched them all. One cygnet was devoured, its head only being found, one perished from too early an immersion in the water, and five grew to be strong, fine birds. No extra precautions were taken beyond a quantity of straw laid by the water which the two Swans made into a nest, if such it might be called. When hatched the young birds were fed on barley meal; but soon learned to eat like their parents—namely, barley soaked in water. It was amusing to see the mother with her progeny on her back. Up to a very recent period, when the young ones were taken away, the old male Swan was extremely pugnacious, and I, for one, should not have liked to have thwarted him.—E. B.

[We have found the best way of saving eggs from the unnatural propensities of hens is to place composition ones in the nest and about their haunts. They pick at these till their beaks are sore, and they give it up at last in despair. It is also worth while to watch the hens to nest, and, as soon as they have laid, to frighten them from their nest, and to take the egg. If this is done two or three times they will give up the practice. The sham eggs are not expensive, and are very durable. They can be had at Mr. Baily's.]

HEN WITH STRADDLING GAIT.

Will you explain the cause of a Cochin hen not a year old commencing to walk with a straddling gait; her toes turned in as if cramped; her tail rather on one side; and the yolk of her eggs with white opaque marks or spots in it?—A BEGINNER.

[The straddling gait is caused by difficulty in laying. She must be watched, and when she begins her eccentric walk, a tail or wing-feather must be taken, and, being dipped to saturation in castor oil, it must be introduced in the egg-passage until it meets the egg, which will then be laid without difficulty. It will only be necessary to do this twice, and a dose of a table-spoonful of castor oil will put all to rights. We suspect you feed too liberally, and that the hen is too fat.]

BEE-KEEPING IN DEVON.—No. XVII.

AN EXCEPTION TO AN OLD RULE—A THOROUGH OVERHAUL—INTERVIEWS WITH ROYALTY—A DRONE-BREEDING QUEEN—RETARDED IMPREGNATION, OR TRUE PARTHENOGENESIS (?)—ROBBERS BEES—A COMMUNITY OF TRAITORS AND THEIR DISTRESSED SOVEREIGN—AN EXCHANGE OF QUEENS—TRANSFERRING A STOCK—ADVICE TO APIARIANS.

"EARLY drones, early swarms," is an old and generally a true adage; but as all rules have their exceptions, I have recently proved that this one is not exempt from the common lot. On the 7th inst. (March), I was surprised at seeing drones issuing from one of my stocks; and having caught a couple by way of assuring myself that there was "no mistake" in the matter, reluctantly came to the conclusion that this colony must have a queen capable of breeding drones only. This is the first instance of the kind which has come under my own observation, as confirming what Huber and others have stated with regard to the effects of retarded impregnation, or possibly illustrating Siebold's doctrine of true parthenogenesis in the honey bee.

This discovery having aroused suspicions as to the state of my other stocks, I devoted the remainder of that day and a part of the next to a general examination of my eleven hives. With the exception of one box in which some of the combs were worked irregularly (but in which I could see brood), every

comb was taken out and carefully examined, mouldy ones were exchanged; and, in one instance, in which comb-building had taken place during the winter, a couple of full combs were substituted for empty ones. All the floor-boards were cleaned and dried; whilst in many cases, where internal moisture was present, the bees were transferred from damp to dry boxes. During this thorough overhaul, personal interviews were sought and obtained with all the sovereigns of the different communities, and I had the satisfaction of finding all apparently in good health and capable of fulfilling their royal functions. In one hive only was there no brood—No II.—a weak stock in which many bees had died during the winter; but even this one had a fine Ligurian queen, whose distended abdomen very plainly indicated that with more genial weather there would be no lack of eggs.

The examination of No. XI, from which drones had issued, proved my suspicions to be correct. There was a good deal of brood, all in workers' cells, but showing by their extreme length and convex coverings that none but drones would be forthcoming. The queen herself was a very dark Ligurian, and the only peculiarity in her shape was about the abdomen, which was long, and although not quite so slender as that of a virgin, by no means so much distended as in the perfect mother bee. Her appearance was, however, perfectly symmetrical, and without the least sign of that distortion of the abdomen described by Huber, who says that in retarded impregnation "the extremity remains slender, while the first two rings next the thorax are uncommonly enlarged." Whether hers was a case of retarded impregnation or of true parthenogenesis I am unable to decide. She was bred very late in the season when but few drones were left, and I gave her sufficient driven bees to make up a stock, on the chance of her turning out all right.

A week afterwards—namely, on the 14th March, I found that my weak stock No. II. had suddenly become extraordinarily active, a constant stream of bees pouring in and out of its narrow entrance. Although to a casual observer it might have appeared the strongest stock in the apiary, the real state of the case was at once apparent to an experienced eye—the hive was being plundered in the most systematic manner by a band of robbers! Never before had I seen a colony of bees, however weak, turn traitors to their queen, but in this instance the fact was undoubted; and although the entrance to the hive was so contracted as to be easily defended, no disposition was evinced to protect their home, but all appeared to have basely deserted without fighting, and were probably aiding the pirates in the transport of their booty.

On opening the hive I found all except the unfortunate queen busily engaged in rifling its treasures. She indeed, with hurried steps and shrunken abdomen, traversed the mangled combs in the direst extremity of distress, being entirely disregarded by the marauding workers which appeared intent only upon pillage.* No time was now to be lost, and the hive was at once shut up and conveyed to a dark cellar until the next day. By this time the imprisoned marauders appeared to have made their peace with the outraged sovereign and seemed quietly waiting for "something to turn up."

But what was to be done? The imprisoned bees were much too few to form even a moderate stock; and if the hive were restored to its place in the apiary a renewal of the attack was certain. Up to this time I had entertained the notion of preserving the drone-breeding queen in No. XI. with the view of securing myself against a repetition of the catastrophe of last summer, when a premature massacre deprived me of nearly all my Italian drones in the month of June. Finding, however, that her progeny were, like herself, so very dark as scarcely to be distinguished from the common species, I determined upon her deposition, and the substitution of the forlorn monarch of No. II.

The capture and destruction of the quasi-sovereign having been effected, a piece of perforated zinc was substituted for the crown-board of the hive, upon which was placed the box containing the remaining bees, combs, and queen of the plundered stock. After being in this position twenty-four hours the

* The consummation of a catastrophe of this kind has been thus graphically described by a writer in one of our quarterly reviews:—"Bees, like men, have their different dispositions, so that even their loyalty will sometimes fail them. An instance not long ago came to our knowledge, which probably few bee-keepers will credit. It is that of a hive which, having early exhausted its store, was found on being examined one morning to be utterly deserted. The comb was empty, and the only symptom of life was the poor queen herself 'unfriendly, melancholy, slow,' crawling over the honeyless cells, a sad spectacle of the fall of hee-greatness. Marius among the ruins of Carthage, Napoleon at Fontainebleau, was nothing to this!"

perforated divider was withdrawn, and a complete union effected. Some sharp fighting then took place, and from two hundred to three hundred were soon killed. After the commotion had subsided I carefully examined the dead, and finding no queen amongst them came to the conclusion that she had escaped. Ungenial weather prevented my verifying this conjecture until the expiration of a week, when I had the satisfaction of finding that she was not only fully installed and receiving all the honours due to her state and dignity, but that she had proved herself capable of fulfilling the duties of her exalted position by laying some hundreds of eggs.

As No. II. was a seven-bar box, I readily consoled myself for my misfortune, and was by no means sorry to have it emptied. As all my colonies, with one exception (No. IV.), were now in shallow eight-bar hives, I determined to make an effort to rid myself of the annoyance of having different-sized hives in the apiary. Accordingly I set to work, cut all the combs off the bars of No. IV., and succeeding by paring down and a little contrivance in fitting them into a similar box to those in which my other stocks are located.

Whilst on this subject I may venture upon a piece of advice to my brother apiarists. It is, never to have but one size for stock-boxes, and to take especial care that every bar fits every hive in the apiary.—A DEVONSHIRE BEE-KEEPER.

BEE-HIVES AND THEIR APPURTENANCES.

(Continued from page 18.)

In your last Number I placed in contrast two as a sample of the many conflicting opinions put forth by authors as to bee-hives and their management; to bring under review all the opposing theories would require folio volumes instead of a corner of your Journal. I will, therefore, in the present paper confine myself to throwing out a few practical hints, drawn from my own experience, as to the most suitable "Bee-hives and their Appurtenances" for the due preservation of our interesting favourites, and affording them a fair opportunity of augmenting their sweets.

The more humane system of bee-management being now generally adopted, with the exception of some of the stiff-necked cottager race—a well-regulated apiary, consisting of a combination of both the depriving and swarming systems, the latter acting as handmaid to the former.

The finest description of honeycomb, realising generally double the price of the run contents of common straw hives under the old brimstone plan, therefore the principal aim of the apiculturist becomes the accumulation of the greatest possible quantity of this article free from pollen and brood in separate compartments of the hive, leaving as nearly as possible what will sustain the inmates of the stock, till the return of another season. To accomplish this various expedients have been resorted to.

Amongst the foremost come *doubled first swarms*. The honey-season in our variable climate being usually so exceedingly short-lived, superior completed boxes and glasses are only attainable by this means, unless the locality be so favoured as to produce very early swarms. *The more powerful the colony, while the staple supply of the district lasts, the greater will be the success; and the more expeditiously the work is got up, the purer and more valuable it becomes.*

Another expedient is substituting *end communications* to supers, in lieu of central communications, in every description of hive employed. To this I previously alluded in some remarks on Stewarton-hives, inserted in No. 610 of your first series; and its importance may justify a repetition of some of the arguments in its favour here. The seat of breeding is the centre, where the heat is chiefly concentrated; consequently, on opening a central aperture the temperature is reduced where it is of the first importance to be kept up; and the rank heated vapour is worse than wasted by being dissipated through the super, discolouring the purity of the comb. Besides, the queen usually perambulating the central combs, is much more likely to find her way up into the super through a central opening, where, depositing her eggs, the comb's destruction is completed. Also, by using side openings, the two classes of bees are more naturally kept together, the honey gatherers of the end combs having free access with their loads up into the super, without being obliged to push their way through the crowd of nurses and pollen collectors of the centre. Although the advantages of such an arrangement are so obvious,

and always are acted on in Ayrshire, yet I have never found it noticed in any work, not even in the admirable "Bee-keeper's Manual" of Mr. Taylor. Should that gentleman, before publishing his seventh edition, indulge in a tour through the above county, making the acquaintance of some of the leading members of the Ayrshire Apiarian Society, he would be astonished at the results effected by a good hive and skilful management in rather a late district, and would find an enthusiastic practical acquaintance with the honey bee that would afford him materials to place the seventh edition of his standard work as far in advance of the sixth as this is of the first.

I can corroborate what this author states at page 194 (fifth edition), quoting from Golding as to the desirableness of exchanging or procuring swarms from a distance occasionally, and as to the diligence of the new arrivals, but am not sure if the benefit ends here. I am led to think an infusion of a little fresh blood into the apiary may be of as much benefit as into the cattle or poultry-yards; having known instances of cottagers' stocks in first-rate localities, isolated for miles from others, gradually and unaccountably dwindling away, till they became totally extinct. A new stock procured, flourishes remarkably for a time, and again in a few years as mysteriously and gradually dies out.

Should your valued correspondent "A DEVONSHIRE BEE-KEEPER" be as successful in spreading the Ligurians next season, as your many apiarian readers heartily wish, we may by-and-by hear the result of a greater cross.

My practice is not to retain a depriving hive longer than the second season; a flagging of energy I have usually observed in the third—besides, the purity of the super is apt to get contaminated by the continuous traffic over the dark comb below. Still, an old hive may sometimes be re-invigorated to work wonders by a second swarm being added—the youthful monarch possibly in that case supplanting her aged rival; still, I prefer the surer mode, taking what honey the hives contain before it gets stale, and starting afresh.

This rule does not hold good with regard to swarming-hives; under favourable circumstances old stocks may throw swarms, and prosper for many years, though I by no means approve of the course. Observing recently in a small farmer's garden a straw hive of very venerable aspect, the lower band nearly gone, I had the curiosity to inquire its age of his better half, whose pin money the hives represented. After a little mental calculation she recollected she had quarrelled with the grocer at the village, the "Great Exhibition year," when it would appear she had purchased his *pro indiviso* half, the hive having been held amicably on joint account of both proprietors for some four years previously: here then, was a fourteen years' establishment. On asking why she had kept it so long, and if she had noticed anything odd about the bees, her reply was "she was sweet" to put it down, it had been *sae* lucky, casting twice every year;* but she thought the bees had "gotten *unco sma*."† She was not a little tickled at hearing the latter peculiarity explained. By judicious management, disposing always of her first swarms at good prices, thus getting quit of old queens and bringing round her second, and stocks with a little spring feeding, this shrewd old dame swelled up the aforesaid pin money, so as to incite the jealousy of her neighbours. One, in particular, determined to outstrip her by following exactly the opposite course, thereby thinking to have earlier swarms and greater success; but what with small returns for her light hives, old queens dying, her heavy hives attracting pilferers, and various causes, she never succeeded—confirmatory of what Mr. Fox so well said as to this, under "Bee-feeding" in No 636, which from my own observation I can heartily endorse.—A RENFREWSHIRE BEE-KEEPER

(To be continued.)

THE CANARY AND THE BRITISH FINCHES. THE GOLDFINCH.

The hybrid produce of the Goldfinch and Canary are said to be capable of breeding again. Buffon and Bechstein both mention it as an accomplished fact. M. Hervey states a case in point. "The young ones that come of these mixed birds, often breed others the next year contrary to the opinion of him that has writ the contrary; and this second mongrel race are so beautiful that they cannot be too high rated. Such are those I saw last year in this city (Paris), which were sold for 500 livres—that is, the mongrel cock and hen and three

* Reluctant.

† Very little.

of their young ones. Nature had never produced anything so beautiful in mongrel birds, I will not here describe the variety of colours they were adorned with. I think the mentioning of the price is sufficient for every one to guess at their beauty."

A gentleman on whose information I can rely, informed me that a barber where he used to go to be shaved, at Cromer, had a pair of Goldfinch Mules that bred again, and that he saw the old ones and their young several times.

I have myself endeavoured to breed from Mules, but without success. I had a cock Goldfinch paired with a hen Goldfinch Mule; they built in a room and laid, but a mouse got in and destroyed the nest and eggs. I had a Goldfinch Mule cock paired with a hen Canary, and though she sat, the eggs proved clear. At another time I had two hen Goldfinch Mules that paired and laid with a cock Canary, but their nests were also disturbed. I noticed what Bechstein observes—that the eggs laid by the Mules are at first small, no larger than peas, but increase in size afterwards. From all my experience I have no doubt but that Goldfinch Mules will occasionally breed, but I believe it is of a very rare occurrence.

If the Goldfinch is paired with a turned-crowned Canary, many of the Mules will be crested, which is regarded by some fanciers as an additional advantage.

At the Crystal Palace Show, 1858, Mr. Nicholson exhibited a

cinnamon-coloured Goldfinch Mule. In 1859, Mr. H. Wardle showed a clear Mealy and also a clear Jonque Goldfinch Mule.

Not only with the Canary does the Goldfinch breed freely, but also with other small birds. Within a very few years Hybrids between the cock Goldfinch and a nestling hen Bullfinch have been exhibited at the Crystal Palace and other bird shows. These are very peculiar, but handsome Mules, of a rich dark plumage, partaking of the character of both parents about equally mixed. To breed them it is necessary that the hen Bullfinch should be very tame, reared from the nest, and while young brought up with Goldfinches; but even then it is rarely that they will make a good nest, and still more seldom that they will hatch and rear their own young in a breeding-cage. When it is found that they have paired, and that the hen is about to lay, it is advisable to cover the bottom of the cage with sawdust, or some such material, to catch the eggs if she drops them, and then hatch and rear them under Canaries.

The Goldfinch has also bred with the Greenfinch. One such Hybrid was shown at the Crystal Palace in 1858, and two in 1859. They were more of a greenish shade of colour, taking more after the Greenfinch, but bearing unmistakeable marks of the Goldfinch.

A Hybrid between the Goldfinch and Grey Linnet has also been exhibited.—B. P. BRENT.

THE RABBIT (*LEPUS CUNICULUS*): ITS HISTORY, VARIETIES, AND MANAGEMENT.

SILVER GREY OR RICHE RABBIT.

THIS species, also known by the name of Chinchilla Silver Grey, is so called from the skin resembling that animal, and for which this Rabbit's skin is sold as a substitute. The name Chinchilla also serves to show the distinction between this variety and the Wild Silver Grey or Silver Sprig. It is in general more developed in form than either the wild or domestic Rabbit. Its fur is dark, and is in part of a silvery grey and part slate colour, approaching more or less to a blackish-brown. The hairs of the fur that are short and soft are of a mouse colour, or pale slate, or bluish; some, the long, firm hairs, are blackish, or a dark slate, and the other long hairs are white, so that the mixture of white, slate, and black varies on different parts of the body. The head and ears are nearly all black with a few white hairs. These white hairs are more numerous on the neck, shoulders, and back; but on all the lower parts, such as the chest or belly, the number of white hairs is greater than those of a blue or black colour.

This Rabbit is bred for its flesh, and still more for its fur, but unfortunately it degenerates in cold climates. There its fur becomes of an iron grey colour instead of remaining silvery, and its skin is reduced in value to only 5*d.* instead of from 1*s.* 8*d.* to 2*s.* 6*d.*

M. Gerard states that it is in Siam, a kingdom of Indo-China, that this race is found in all its purity. It is bred there chiefly

for its fur, which is much valued by the northern inhabitants. Its strong, robust constitution renders the breeding of it easy and it there prospers without degenerating. It is tended by the Siamese about the same as a tame Rabbit.

In climates where the temperature alters its qualities, it requires particular care, if you wish to profit by its skin. Warmth must be secured to it which the winter denies it. The uniform temperature of burrows that suit the wild Rabbit, is equally suitable to tame Rabbits. To procure for them this temperature one should make round their burrows a terrace of sandy earth of about a yard or a yard and a half high, retained from sliding down by a wall perforated with holes on a level with the ground. The Rabbits establish themselves in the bank through the holes, and remain there in all seasons. In winter they only come out to feed. The darker and warmer the burrows, the finer, more silky, longer, and more lustrous will be the fur.

Still, there will be sometimes among them a few females whose fur will be spotted with white. The fur of the males is generally of a finer quality. To obtain from this species a finer fur, castration of the males is in use, which operation should be performed when the animals are about three months old. It not only improves their fur, but increases their size, and renders a quarrelsome animal quite docile, so that these emasculated animals can be kept together in large quantities.

The darker shades are the most prized by the furriers at the present time, and with which they make muffs more particularly; but much depends upon fashion, with which the warrener must not be influenced, but must endeavour to have his stock of a medium colour, neither very light nor very dark.

In consequence of the increased demand for the skins of this species, several new warrens have been formed in the south of France, and these Rabbits are in great demand on the Continent at the present time.—R. S. S.

(To be continued.)

VARIETIES.

CLOTHES-MOTH, a name common to a number of species of small moths of the genus *Tinea*, the larvæ or caterpillars of which are extremely destructive to woollen clothes, furs, stuffed quadrupeds and birds, &c. *Tinea destructor* is one of the most annoying of these insect pests. It is of a satiny buff colour, the wings deflexed when at rest. The larvæ is about a quarter of an inch long, with only a few hairs, white, with a slate-coloured line down the back, an ochreous head, and sixteen legs. *T. tapezana* has the upper wings black at the base, the rest of the wing white. *T. sarcitella* is another very common species, of a silky grey colour; the head, thorax, and base of the superior wings white; the wings folded flat on the back when at rest. The larvæ is covered with scattered hairs. These moths are most abundant in the warmer seasons of the year, but their larvæ carry on their destructive operations even during winter. Guided by instinct, the female moth lays her eggs where the larvæ may find their appropriate food, consisting of substances indigestible to almost every other creature; and the larvæ being furnished with minute but strong and sharp jaws, not only begin to eat as soon as they are hatched, but to cut the fibres of the substances on which they feed into little bits, and to unite them by means of a glutinous silk of their own producing, so as to form for themselves cases, lined internally with silk; and in these they constantly abide, adding to them at the anterior end as their own increase of size requires, and also widening them, by slitting them down the middle, and mending them with additional materials. All this may be beautifully observed by transferring the same moth-larvæ to different pieces of flannel in succession, of different colours. The larvæ of *Tinea tapezana* works its way through woollen stuffs in an arched gallery, carrying its little case with it. *T. pellionella* makes similar tunnels in furs. *T. granella* is destructive to books as well as to grain. The best means of preventing the ravages of moths are perfect cleanliness, frequent inspection of articles, and their exposure to light and air. Spirit of turpentine is used for killing them; the vapour arising from a sponge dipped in this liquid is fatal to such as it sufficiently reaches; they are also killed by the heat of a brisk fire or of an oven.—(*Chambers' Encyclopædia*.)

INDIARUBBER WATERPROOF VARNISH.—I have used a solution of Indiarubber and turpentine for about twenty years as a waterproof varnish for my boots and shoes. I make the application before blacking is put on, or else remove the blacking by water. When the leather is moist, I take the solution of Indiarubber and apply it with a rag, taking care to rub it in; then I put the boot in a moderately warm place until the whole is absorbed. The process is repeated twice, or until the pores of the leather are filled, when the surplus is wiped off. In a few days afterwards blacking may be put on, and the leather will polish well. By this method of treating my boots, I make them not only watertight but also much more durable, and the leather is always kept soft and pliable. I treat every new pair of boots in the manner described, and effect a considerable annual saving thereby.

CURING HAMS.—At a late fair of the Maryland State Agricultural Society, the first premium was awarded to hams cured as follows:—"To 150 lbs. of ham, take 1½ lb. saltpetre, four quarts of fine salt, with molasses enough to make it a paste; rub well on the flesh side; let it lie four weeks; make a pickle strong enough to bear an egg, let the hams lie in it four weeks; then hang and smoke. Two days before removing from the smoke-house, paint with black pepper and strong cider vinegar, after which bag them.—(*Scientific American*.)

THE SUNBEAM'S GRAVE.—Nothing in this vast creation is ever

lost. Individuals may be losers through carelessness, but to the world at large no created substance can be lost. One combination of things is often changed into another, but no ingredient is ever utterly destroyed, for at this moment the created universe does not contain one particle of matter more, nor one particle less, than belonged to it that day it came fresh from the creating band of Him who made all things very good. Never did a sunbeam shine in vain, and therefore no sunbeam that ever streaked this world with light could be finally lost. Yet the sunbeam, lovely as it is, had its grave, and there sometimes for unnumbered ages it has slept in undisturbed repose. What is coal but latent sunbeams, which need only to be ignited to start out again into active life? The sun, when many thousand years younger than he is now, cast forth his radiant beams on the surface of the world, and noble trees of Ferns and other aerogens started at his bidding into vigorous life; they lived, died, and underwent changes which made them coal—yes, coal! and the old sun he did it all. These sunbeams have long been buried in the form of coal; and though by ignition their resurrection-life is but a dim shadow of their early brightness, they are yet sunbeams. We have nothing but sunlight in summer or in winter, think or talk as we may. The fire on our hearths, the gas in our tubes, the oil in our lamps, and the candles on our tables, are all the products of the sunbeam. We kindle them, and in the very act raise the sunbeam from its grave, and send it forth to run perchance a long cycle of changes ere again it rests in such a place as that we have dragged it from.

OUR LETTER BOX.

GAME BANTAM COCK NOT PAID FOR (*E. Fisher*).—See the purchaser in the County Court. You have no other remedy. We have repeatedly warned our readers not to deliver poultry without prepayment to stranger purchasers.

BANTAM PRIZES AT CHESTERFIELD (*R. Baines*).—The Managing Committee of a Poultry Show must regulate their prizes by the entries usually made in the classes. The greatest number of Bantam entries usually are in the Game Bantam class, and the exhibitors in that may fairly expect, that as that class enriches the Society's treasury more than the White and Black Bantam classes, so it ought to have higher awards. We suppose this consideration influenced the Chesterfield Committee, but we do not know.

CHARACTERISTICS OF AVESBOURY DUCKS (*C. S. J.*).—To be winners they must be heavy, but the weight must be the result of large size, and not of feeding. The head should be large, the bill very pale flesh colour or French white, long and broad; free from black spots or yellow or orange shade. The body long and broad between the shoulders. Entire colour pure white.

CALL DUCKS, LENGTH OF INCUBATION.—Having bred "Call Ducks" for some few years, I can assure Mr. B. P. Brent that their eggs are quite as long in incubation as those of other Ducks—a fact I have proved in setting their eggs with those of other varieties.—*T. HARVEY D. BAYLEY, Ickwell House, Biggleswade.*

WATER FOR PARROTS (*A Lady, A. Z.*).—We regret to hear that any one so totally without knowledge of the subject ventured to advise you to keep your Parrot entirely without water! Well might it "cease from talking," and well might it "beat itself against the cage when it saw water!" The bird must have suffered excessively. Always let it have a constant supply of water for drinking, and daily when let out place a soap-plate filled with water on the floor. The Parrot will differ from birds of the same kind we have known if it does not soon indulge in a bath. It is the best preventive of a Parrot eating its own feathers. It should have very little hempseed. The canary seed and bread sopped in water form a much better diet. Of fruits the Parrot usually prefers the cherry.

GOLDFISH MULES (*An Old Friend*).—If you put two hen Canaries to one Goldfish in the same cage, as you propose, the hens should first be put together to become acquainted, or they will quarrel. You will have seen my remarks on Mule breeding in THE COTTAGE GARDENER for March 26th, which will more fully answer your inquiries. The same will apply to Linnet Mule breeding.—*B. P. BRENT.*

TEACHING A BIRD TUNES (*Susanna*).—It is best to teach birds one tune at a time, but much depends on the capacity of the individual bird as to whether he will learn even one tune perfectly, or if he can master more than one. I am not aware that Chaffinches have been taught tunes, but they sometimes learn other birds' songs as well as varieties of their own.—*B. P. B.*

LONDON MARKETS.—APRIL 8.

POULTRY.

There is still a very small supply of poultry, and were it not the trade is unusually dull, prices would be higher than common.

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 53.2° and 36.4° respectively. The greatest heat, 77°, occurred on the 19th, in 1854; and the lowest cold, 20°, on the 16th in 1847. During the period 142 days were fine, and on 96 rain fell.

EFFECTS OF LAST WINTER UPON PLANTS
IN VARIOUS PARTS OF ENGLAND.

THE winter which has just passed over us, though an exceptional one, was such as returns at intervals, and he will do most wisely as a gardener who learns thoroughly the warnings and lessons which it imparts.

We have several communications upon the subject, and will commence publishing them by placing before our readers to-day the effects that have been observed at the Kew Botanic Garden. This claims priority, not merely by its official position, but because there are cultivated together a greater number of specimens and species in each genus than can be met with anywhere else in the British Islands.

PLANTS THAT HAVE BEEN INJURED BY THE WINTER OF 1860 AND 1861 AT KEW, BEGINNING WITH THOSE ON THE OPEN LAWNS AND SHRUBBERIES.

Pinus insignis, some much injured, and others killed.

Pinus muricata, much browned.

Pinus halepensis, all killed.

Pinus australis, much browned.

The rest of the Pinuses quite green, and in their usual forwardness.

Quercus ilex. All that the varieties of the evergreen Oak indicate is an earlier shedding of their leaves than usual.

Quercus suber, most of the young wood of last year killed.

Quercus glabra, killed, but is alive against a wall.

Cupressus torulosus, much browned, and some appear to be killed. This kind at Surbiton, with Mr. Ross, is hardly browned.

Cupressus Uxheana, suffered to the same extent as *torulosus*.

Cupressus sempervirens, the older plants much browned; but this Cypress is nowhere seen healthy or vigorous on the light lands in the valley of the Thames. The finest plants of it in the country are on the chalk. Dozens of the most healthy-looking at Shrubland Park are reported by Mr. Taylor as quite killed.

Juniperus repens, only one plant dead from some other cause.

Magnolia grandiflora, all its varieties have lost most of their leaves, and the young wood of last year appears to be killed.

Veronica lavendulacea, killed.

Laurus nobilis (the Sweet Bay), suffered much, many being killed to the ground. One of the largest specimens

on the lawn in front of the succulent-house, and much exposed, was killed to the ground in 1823, again in 1838, and a third time in a subsequent year, has only been browned this winter.

Phillyrea rhamnus (the common Phillyrea), many have lost all their leaves and the ends of the young wood; others have escaped with a little browning. Only browned in Surbiton.

Arbutus unedo, many in the low, wet parts of the garden seemed killed; in other parts they all look as green as usual. Some are browned at Surbiton.

Cistus ladaniferus (the Gum Cistus), all killed, and the same at Surbiton.

Buddleia globosa, killed to the ground. It is strange that in the very north of Scotland this plant is seldom hurt by frost.

Tasmannia aromatica, a smooth evergreen, killed.

Torreya taxifolia, one plant dead; but probably from recent removal.

Maytenus chilensis, a rhamnus-looking evergreen, killed; but safe against a wall.

Euonymus japonicus and *variegatus*, killed to the ground, and much hurt against a wall. Some cuttings of it struck last summer in pots, and left to their fate, are not the least hurt. Four fine plants of the green *japonicus*, cramped in small pots for two years in the Experimental Garden, and plunged under an east wall, have not had a leaf browned; but all over the place every other plant of both kinds is killed.

Cerasus laurocerasus (the common Laurel), green as usual, except where the wind nipped the young shoots round some corners, as it always does when charged with the smoke from the factory chimneys of Brentford, which in general is more injurious to evergreens at Kew than the frost.

Ligustrum lucidum, much hurt, but not so much so as at Surbiton. In the Experimental were several very large plants of it which are all killed to the ground.

Araucaria imbricata, all the strong plants—and they might be numbered by the score—are as dark green as those on the highlands of Chili, but a few of the young plants are touched at the end of the shoots—probably as much by the smoke from Brentford as by the frost.

Rhododendrons—all the kinds from Sikkim that have been planted out in the happy valley beyond Mount Pleasant in the pleasure-ground are quite safe; but they were *sub tegmine fagi*—or, in other words, under the shelter of the large Spanish Chestnuts, the fagi of the Mantuan bard. But the scarlet hybrids of the first and second generations from the great Nepal arboretum have suffered considerably, and some of them have lost parts of their branches. All other hybrid *Rhododendrons* are as safe as *ponticum*.

Kniphofia uvaria—the name at Kew for *Tritoma uvaria*, glaucescens of other folks—has suffered severely, and some must have been quite killed at Kew. Two-year-old suckers of it in the Messrs. Jacksons' Nursery at Kingston have not been quite killed to the ground in an open exposed part of the nursery. In the Experimental,

on the grass and slightly mulched, not the least hurt; and in my private garden they began sprouting early in March, and by the 1st of April made six-inch leaves.

Gynerium argenteum (the Pampas Grass), all killed to the ground, and most of the plants were supposed to be killed, root and branch; but some are beginning to sprout.

PLANTS AGAINST WALLS.

Euonymus Hamiltonianus, killed.

Cerasus ilicifolia, much hurt.

Benthamia fragifera, looks seriously hurt, if not killed.

Cistus formosus, killed.

Ceanothus azureus, very much hurt, but not killed to the ground.

Ceanothus papillosus, the same.

Eugenia Ugni, killed.

Eugenia apiculata, only much hurt.

Escallonia macrantha, killed; ditto, *E. montevidensis*.

Arctostaphylos tomentosa, slightly browned.

Cneorum tricoecum, much hurt.

Rosa bracteata (Macartney Rose), quite killed, and the only Rose killed at Kew.

Colletia cruciata, *alias* *Biotensis*, killed outright.

Fabiana imbricata, killed.

Jasminum nudiflorum, much browned. Against my house it has been in bloom from October to March, except during the frost, the flowers only being killed.

Naudina domestica, killed. I have known it killed in the north of Scotland by 15° of frost.

Solanum jasminoides, killed only to the ground.

Myrtus communis (the common broad-leaved Myrtle), many of the branches killed; the same in Kingston, under one fold of mat. At the Experimental a plant 15 feet high in a sheltered recess, and with one fold of frigi domo, is quite safe.

Plagianthus sidioides, killed to the ground.

D. BEATON.

SELF-VENTILATING ORCHARD-HOUSES.

EVERYBODY knows the construction of Davy's safety lamp for coal mines, the wick being surrounded by a wire gauze, of which the interstices, whilst freely admitting the oxygen needful for combustion, are so minute and cooling as to prevent the flame from communicating through them with any firedamp there may be in the atmosphere of the mine. What think you of a safety house on a similar principle for the protection of tender fruit-blossoms, and the ripening of such fruits as do not usually reach perfection in our climate?

Two summers ago we had a severe hail storm, breaking, more or less, about one-half of the panes in the lights of our Strawberry-frame. In the following spring the plants were covered as usual, but without repairing the damage to the lights, which were allowed to remain unmoved till the fruit was nearly ripe. Ventilation was left to look after itself, and as the rain fell it found its way through the broken panes to the plants beneath. The fruit ripened a full fortnight before that in the open ground.

It has occurred to us since, that a modification of the Davy lamp principle might be applied with advantage in the construction of orchard-houses. These erections, interesting and elegant in their results, will never give a profitable return to the labour bestowed until the everlasting attention to ventilation and syringing is superseded. What we want, but which we shall never altogether get, is an orchard-house in which, with only the same attention as is called for in out-door culture, we shall have nearly the result of a more southern climate. Now, suppose the glazing of the roof and sides of an orchard-house so arranged as that between every pane there should be a space large enough to admit free ventilation and the ingress of the rain as it falls, at the same time retaining the summer heat, and excluding the March and April frosts. It may be a matter of lengthened experiment whether these spaces should be an inch or one-eighth of an inch wide, and whether they should occur at intervals of 3 inches or 30 inches, but that they will accomplish a portion at least of what is needed we have little doubt. It may be a question also whether the spaces should be open, or overlapped

by the pane of glass next below them. Our Strawberry plants were quite free from the attack of any insect, and involved no more trouble than those in the open bed adjoining.—FRUIT-EATER.

FLORISTS' FLOWERS.

DEFINITIONS are avowedly difficult things. We have only to try our hand at one—let it be the very simplest—and we shall soon find that we shall probably be as far wide of the mark as he who in defining a man could only get beyond "a two-legged animal without feathers;" and though I have a tolerable idea of what florists' flowers are, yet I should find it amazingly difficult to give a general definition that would meet all and exclude other flowers which might claim the honour. In an authority to which, I suppose, all the readers of this Journal feel bound to bow—the *Cottage Gardeners' Dictionary*, they are defined as "those which, by their beauty and fragrance, power to produce permanent varieties, and facility of cultivation, are so largely in demand as to render them specially worthy of cultivation as an article of commerce." Very well. Now come to the test:—Is the Auricula so easy of cultivation as to be specially worthy of cultivation? There are not a dozen growers for sale in the kingdom. Would a florist allow the Anagallis or Tuberosa to be florists' flowers, even though enumerated in the list appended to the close of the same article? Is the Hydrangea a florist's flower? Would any one call the Rhododendron one? Yet these fulfil the above conditions, and are classed as such in the notice to which I allude. And on what principle is the Hollyhock excluded from the list? it surely has taken a high position as one. There are some, however, about which there is no doubt. Carnations, Chrysanthemums, Dahlias, Pansies, Pelargoniums, Tulips, Roses, Pinks are universally acknowledged as such, and I wish to say something in their behoof; for really the rage for bedding out seems to push them very much into the background.

Any one who has watched the progress of any one particular flower in its advancement towards perfection, must have been struck with the wonderful power that careful hybridising has in not only producing new varieties, but in completely altering the character of the flower. I have, *e.g.*, before me a plate published in the Horticultural Society's "Transactions" many years ago of Chrysanthemums then esteemed, and one published in this month's "Florist," and it would be impossible to suppose a greater difference between flowers even of totally distinct species; while, on the other hand, there seems to be a point which, when it is attained, improvement seems well nigh impossible. I know one ardent admirer of Pelargoniums who gave up in disgust ordering new varieties, because, he said, there was so little improvement or change from year to year.

Again, take Cinerarias. In a particular line of colour it seems impossible to exceed the beauty of some of the varieties grown. A sort named Perfection, let out by Mr. Turner, of Slough, two years ago, seems to me still worthy of its name; in shape, colour, size, and growth one could desire nothing better. On the other hand, Auriculas and Tulips seem capable of great improvement even now. In the former, it is remarkable how few really perfect flowers to an educated eye there are; while in the latter, the manner in which English raised varieties are beating out of the field the old Dutch ones is very remarkable; and one eminent amateur, Mr. Richard Headley, of Stapleford, has challenged all the Tulip growers in the kingdom to show his Adonis, a new flower, against any other Tulip.

When, however, a flower has by hybridising reached the desired point, I by no means say that it will not reward the raiser to continue it; for so sportive are these flowers, that he can never tell what new strain he may hit upon. Thus a few years ago my friend and neighbour, Mr. Banks, of Shalden, the most successful raiser of Fuchsias in the kingdom, raised a flower, of which he said, "I know it will be very hard to beat;" and perhaps in its particular style it is still untouched. But he went on; and any one who saw the immense crinoline corollas in those that received certificates at the Floral Committee last year, will surely be unwilling to say that he has gained nothing by his perseverance. A new strain has been entered on, which may yet produce something more wonderful than any that have gone before. Look again at Pelargoniums. Some years ago there was but one class; then Fancies came on the stage, and, though very badly shaped at first, yet the care of the hybridiser has made them now perfectly beautiful in form

and delicate in colouring. A sport in what was called the florists' class came with a spot in the lower petals. It was immediately caught at, and now we have a distinct class of spotted *Pelargoniums*.

Our lively neighbours over the water, fond of and originators of everything bizarre, have latterly been introducing some novel colours into their flowers. At present the shapes are bad; but French varieties form a distinct class, and before long we may hope for as good form in them as in the other classes. This is an instance within our own memory of what has been done and what yet may be done in any department of florists' flowers.

There is one point at which, I think, all raisers of seedlings ought to aim, and in which much may yet be done—and that is, getting plants of good habit, for the delicacy of many kinds has prevented amateurs from venturing on them. What a glorious thing to get such an *Auricula* as Booth's Freedom with the habit of John Bright—and surely this is to be done. In Carnations the same advance may be made. Every grower of them knows that in Rose Flakes there is nothing to beat Flora's Garland; but she is coy, hard to please, and hence has kept up her price beyond many not one quarter as old as she is. Mr. Headley, of Stapleford, has recently raised a seedling, which obtained a first-class certificate from the Floral Committee last season, and which is figured in Mr. Moore's "Floral Magazine" this month, called *Rosa of Castille*—apparently as good a flower as Garland, and said to be of vigorous habit. If so, though Mr. Headley has been a seedling raiser for so many years, he will even now have added something new.

Again, in Pinks. The raiser against whom none can venture to appear is Dr. Maclean, of Colchester. He might have thought two or three years ago, "I can never beat those I have raised." Well, independently of those which appear for the first time this year, I saw in his garden what will be, I am sure, a favourite—a yellow Pink—at least, a very decided primrose colour when first opened, and in the bud quite yellow. Who can tell whether this may not lead off into a fresh strain altogether of this sweet florists' flower?

These are encouragements which, in the present state of gardening, florists need. What can be to those who have time a more pleasant occupation than raising seedlings? One must fall in with the fashion; but what more wearying than this eternal round of reds and yellows? The same beds, the same flowers year after year, and then only looking at a plant as it may do for bedding—as I heard a lady cry out at *Bougainvillea splendens*, "What a charming contrast it will make for a bed!" I know it is urged against them that their bloom is so short—that you can never rely on more than three weeks or a month. Well, as Lord Palmerston said to Mr. Rowcliffe about the hundred honest men, I think that is a very good length of time. You may begin your year with Pansies and Auriculas, have them in perfection from the middle of April to the middle of May; then Tulips take their place for three weeks or a month; then your Pink-bed comes into full bloom; it is hardly past its best when Carnations and Picotees come in all their grand beauty, to be immediately succeeded by Dahlias and Hollyhocks, and these again by Chrysanthemums, lasting until the dark and dreary month of November; and thus the florist is never without his collection to look over and take care of, and be delighted with. This he may still do, and yet have his garden somewhat in the fashion.

There is an objection sometimes made that they are all so much alike, but I take small account of that. Of course, to those who have no eye for them, they are. A hundred Etruscan vases would just be the same; yet the connoisseur will point out to you variations in each well deserving of minute attention. Let me, then, put in a plea against the prevailing tendency to run them down. Let me urge real lovers of gardening to be no way deterred from trying to add fresh beauties to our lists; and let me assure them, as one who has long known them, that every year adds fresh novelties, and gives hopes of still further progress.—D.

VARIEGATED ARABIS.—As a correspondent inquires about this plant, I may say, in addition to what I recorded in a former article in its favour, that it is as hardy as a wild daisy, the past winter not having tinged a leaf of it. The plant is now (April 5th), in full flower, or nearly so; and though some people object to its blooming, I always allow it to fairly expand all its florets before cutting them off—as, by cutting them early, the plant

makes an effort to send up more flower-stems, and thereby weakens itself. Cuttings or slips strike freely all through the summer months; but the easiest way is to put in a quantity at the same time that *Calceolaria* cuttings are put in, which is from the middle to the end of October. I have several hundreds that were so put in last autumn in rows in a cold pit, with some wooden shutters to cover them during the severe weather, and almost every cutting is now a plant. It is certainly the most compact plant we have for low work; and as an edging for beds on grass has the advantage of looking well all the winter by being left there, which is not the case with *Cerastium tomentosum*, Variegated Balm (or Mint), or *Cineraria maritima*. But it is also useful to improve the appearance of naked beds in winter, when grown anywhere in reserve to plant out in patches in the autumn when the other plants are removed, as it can be planted with a good ball at any time. Even when in full flower it receives little or no injury.—J. ROBSON.

NEW BOOKS.

ARTHUR YOUNG'S FARMER'S CALENDAR.*—Of this work of Mr. Morton we need hardly say it is done carefully and well, and that we cordially commend it to our agricultural readers as a well-executed book for practical reference. But why call it *Arthur Young's Calendar*? Young has been in his grave more than forty years, and he published this work half a century previously. It is true that Young is well entitled to the grateful remembrance of every English farmer, for he was one of the great benefactors of the science, when Coke, and Francis Duke of Bedford, and Davy, and a few other enlightened patriots were laying that foundation on which science and practice have since raised so noble a superstructure; but the progress of knowledge has rendered the larger portion of their labours obsolete; and the works of Arthur Young are certainly not an exception to that conclusion, and no one knows the fact better than Mr. Morton, who has so well re-written the work. Like his editor, Young was not only a popular author, but a practical farmer. Born in the year when *Jethro Tull* died, he seemed to inherit all the genius and indomitable perseverance of the author of the horsehoe husbandry. His characteristics were great zeal, enterprise, and energy, with a copious flow of plain and intelligible language, which the meanest capacity could readily comprehend; and although he possessed few claims to be ranked as a scientific farmer, yet he succeeded by his labours in exciting a general love of agriculture in the upper classes of his countrymen, which has, since his day, never materially subsided.

A memoir of this extraordinary man was published soon after his death by Dr. Paris, his friend and medical attendant, who well described him as having filled a large space in the public eye for a long series of years, but whose name and talents commanded still greater notice and respect in foreign countries than in his own. That he reflected lustre on the age and the country in which he lived can be hardly denied. Of what other philosopher can it be said that at one time he entertained under his humble roof pupils of seven different nations, each of whom had been sent to him for instructions in agriculture by his respective government? "I was lately informed by his daughter," added Dr. Paris, "that the late Duke of Bedford breakfasted at Arthur Young's farm, at Bradfield, on one of the mornings of a New-market race meeting, and was met by pupils from Russia, France, America, Naples, Poland, Sicily, and Portugal." His numerous works are distinguished by vivacity of thought, quickness of imagination, bias to calculation, and fondness for political speculation; and had they been less successful, posterity might, perhaps, have regarded these traits of genius as fatal defects, and as pregnant sources of fallacy and disappointment.

GLASS OF ORCHARD-HOUSE BROKEN BY FROST.

I HAVE the charge of an orchard-house, in the glazing of which there is some serious mistake, for during the winter seven dozen panes of glass were broken in it. The length of the house is 80 feet; breadth, 18 feet 6 inches, glazed with 24-oz. glass, 20 inches wide by 12 inches in depth, the rafters 6 inches deep,

* *Arthur Young's Farmer's Calendar*. Twenty-first edition, re-written and extended, by J. C. Morton. London: Routledge, Warne, & Routledge. 1861.

by 2 inches in width. They are not grooved, but a small slip of wood is nailed down the centre of each rafter, 1 inch wide by three-eighths of an inch deep: consequently, when the glass is properly bedded, it is nearly level with the top of the slip, on which is fixed with screws a water-board, on removing which I always find the slip very wet. The laps of the glass are from 1 inch to 1½ inch. On each side of the house is fixed a small metal stove on the side border, 9 inches by 10 inches; the chimney-pipe goes directly outside, being only 18 inches long. I should be obliged by your kindness in pointing out the defects of the house, and whether these two stoves would have prevented the breakage of glass if properly kept going. I may remark, that last year, when properly attended to, I noticed 12° in the centre of the house.—ALPHA.

[All the data you have given to us do not thoroughly account for the breakage of the glass. The rafters are strong and substantial enough. The depth of the slip we would prefer for such heavy glass to be from one-half of an inch to three-quarters of an inch, or even seven-eighths as you propose; but the shallowness would not cause the breakage. We do not understand about the water-board fixed above the slip. We have just done a house with half-inch slips on the centre of the rafter, and used 16-oz glass. The half-inch slip is quite deep enough for that; but as said above, for your weight of glass we would prefer one-eighth or one-fourth more. No water-board would then be wanted. We presume that the breakage is owing chiefly to two causes: first, glazing too tight, so as not to leave room for expansion and contraction; and secondly, if the laps are from 1 inch to 1½ inch wide, they would hold so much moisture between them, that a severe frost would be apt to make them fly by the ice expanding. A lap of from one-quarter of an inch to three-eighths of an inch would be an improvement. We do not think stoves have much influence one way or the other. We can form no idea of where they are by your description. Do you mean that the stove altogether is only 9 inches by 10 inches, or that that is the size of the firebox merely? It is bad economy taking the pipe directly out of the house. Two iron stoves in such a house, properly managed, ought to prevent a severe frost penetrating. See what Mr. Fish has done with a fair-sized stove, and what he has said about them, and Mr. Rivers' brick stoves in recent Numbers. For such a house the stoves should be placed within 10 feet or 15 feet of each end, and not on the sides opposite each other. The more pipe in the house, the more heat would be given off, but the pipe must not go above 2 yards or 3 yards in a horizontal position. We would prefer an upright shaft, then going through the roof.]

NEW AND RARE PLANTS.

GUSTAVIA PTEROCARPA (*Winged-fruited Gustavia*).

Nat. Ord., Myrtaceæ—Barringtoniæ. *Linn.*, Monadelphia Polyandria. An evergreen stove tree, native of the banks of the river Mana in French Guiana. Flowers white and fragrant.—(*Bol. Mag.*, t. 5239.)

DROSEREA SPATHULATA (*Spathulate Sundew*).

Nat. Ord., Droseraceæ. *Linn.*, Pentandria Tri-(Penta)-gynia. "A lovely species," imported accidentally in the soil of a Wardian case from south-eastern Australia. Requires a warm greenhouse. Leaves rosulate, and flowers purple.—(*Ibid.*, t. 5240.)

CISTUS VAGINATUS (*Sheathed-leaved Cistus*).

Nat. Ord., Cistaceæ. *Linn.*, Polyandria Monogynia. It has been called also *C. candidissimus* and *ochreatus*. Native of Teneriffe. Cultivated in 1779, but until recently lost to cultivators. This is far more beautiful than many newer plants. Blooms in June. Flowers large and rose-coloured.—(*Ibid.*, t. 5241.)

ZAMIA SKINNERI (*Mr. Skinner's Zamia*).

Nat. Ord., Cycadaceæ. *Linn.*, Diccia. Native of Isthmus of Panama. A stove Cycad about 5 feet high.—(*Ibid.*, t. 5242.)

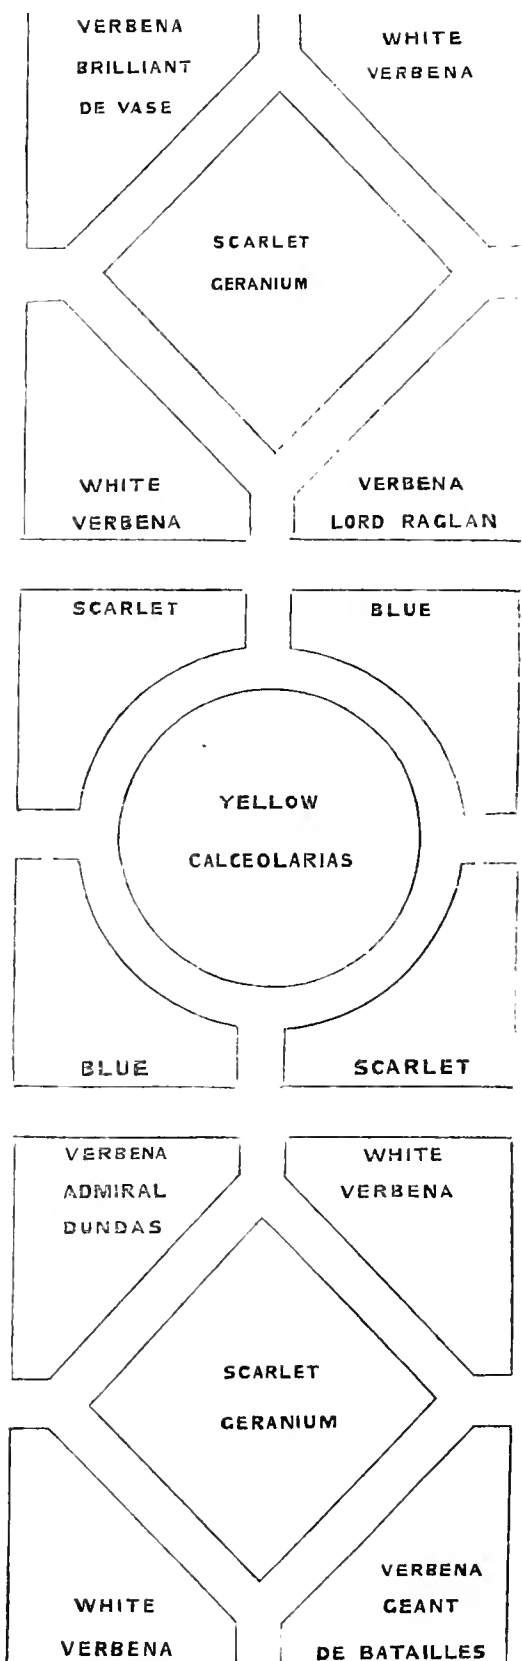

CONVOLVULUS MAURITANICUS (*Mauritanian Bindweed*).

Nat. Ord., Convolvulaceæ. *Linn.*, Pentandria Monogynia. Native of North Africa, near Constantine. Flowers blue; bloomed last October in the open air, in Mr. W. Thompson's garden at Ipswich.—(*Ibid.*, t. 5243.)

GEOMETRIC FLOWER GARDEN.

Will you be kind enough to inform me if the enclosed arrangement of colour in half my garden is suitable? I am

FIG. 1.

quite at a loss how to arrange the diamond-beds, or whether the border should be all one colour—say Flower of the Day.—
A YOUNG BEGINNER.

[Here is the one-half of a geometric flower garden laid out in groups, with cross walks between them. Each group is complete in itself, and planted cross-cornerways, in such a manner as no critic can find fault with. It is an excellent plan for many situations, and for very limited places near large towns, where rents are high, and gardens are more in name than in length or breadth.

Suppose this figure occupied the centre of the grounds to a house rented at £150 a-year, a walk down on each side of it, then a border on the right of one and the left of the other, and then the boundary walls, there would be no more economical way of doing it than this, or something on this model or style. There is not a particle of grass in the whole. But a city man, whether he be rich or poor, carries the same notions of turf into the country which we of the country feel when we see the black-birds with green turf in the bottom of their cage in London—we seem to think the birds could not live in town without it. But nobody seems to think or know that so much grass in such confined spots is the reason why ten doctors assist the pulse

where one might be sufficient if there was no grass inside the garden at all. My own garden is the most open in all Surbiton, yet there is not a blade of grass in it to retain damp, and never shall be as long as I live. That, and not allowing standard trees to choke up the free circulation of the pure air from the Surrey hills, is the very reason that all grades of the inhabitants visit me in my den, except the doctors, and they never come near me, because they have never a moment to spare from visiting other people.

I never counted how many scores or hundreds of such gardens could be made out of one statute acre of land, and every one of them with two rows of tall trees down the whole way; then so many evergreens; then the breadth of a pair of sheets in grass down the middle, which is too damp to walk or stand on for ten hours out of the twelve the year round; but children and the female branches of families cannot resist the temptation of getting on the grass, "it is so enticing," "so nice," or "so like the country." All that is quite true, yet it is also the shortest road to catch colds, and they lead to worse results. The planting of such figures need not necessarily be cross-cornered, as it is here, but that gives the opportunity of a change of planting a second time.—D. BEATON.]

DIAMOND GEOMETRIC PANEL FLOWER-BEDS

HERE, from "A YOUNG BEGINNER," is the first instance of the diamond geometric panel being placed before the British gardener in black and white, as far as we know. Whether as a single figure in front of the drawing-room window, and between it and the public road, or as a sunk panel on grass, or as one of a pair in any suitable position, it is one of the simplest to plant, and may be made most telling in effect by a judicious planter of all the designs that could be got into the same compass.

The requirements of this design demand imperatively that the two centre figures, 1 and 2, be planted exactly alike in colour, and with the same kinds of plants. The framework of our 1 and 2 is represented by the figure 9; it may be all of gold and silver in colour. A band of *Cerastium tomentosum* on one side—the side of the inner walk, another band double the width of the *Cerastium* on the outer side of *Stachya lanata*, and a row of specimen plants of the Golden Chain along the centre, just touching when they are planted; then if there is more space left between the gold and silver than is desirable, insert dark blue or light blue, with a thin line of *Lobelia speciosa* or *Lobelia ramosoides* on each side of the Golden Chain. I saw your demand for *Stachys* anticipated at Pine Apple Place Nursery, and I have no doubt but most of the nurseries have been thinking of what you would be at. The worst of it is the price of such large Golden Chains.

Let us therefore try it again. One side *Cerastium*, the other variegated *Alyssum*, or *Mangles* Variegated *Geranium* trained down, whichever of the two is cheapest or is in stock, with a Tyrian purple along the centre—the good old Orach or the *Atriplex hortensis rubra* of the seed lists; but that is neither rubra, rubescens, nor rubicunda, but pure and simple purple. But put in *Perilla* instead, it will need less looking after; and if it is two shades darker, that amounts to as many degrees in

contrast. If we should all live till next year we might muster up enough of *Arabis variegata* to go all round and round, which is half a Golden Chain of itself, and that too on the outside then to relieve the middle, nothing is so good as Baron Hugel, and *Lobelia speciosa* on each side of it.

The two diamonds may be anything you like, so they be both the same. What I should put in would be Crystal Palace Scarlet *Geranium*, edged with the variegated *Alyssum*; but Flower of the Day and *Lobelia speciosa* would be just as good,

and yellow *Calceolarias* without an edging equally good. Then if Baron Hugel took the place of Orach or *Perilla* in the frame, I would centre the Flower of the Day with one of them, or the *Calceolarias* with a yellow brownish kind of the same. The opposite beds, 3 and 4, must, of course, be blue or purple, no matter which; but nothing lilacy must go there on account of what is in 9, which embraces two sides of 3 and 4. The corner beds must be planted crossways, if this figure follows immediately after the last, on the grass or gravel terrace—as 5 and 8 the same; plant 6 and 7 ditto. If the figure, or any like it,

is seen from the windows from one end, they should not stand crossways; but the two nearest the eye to be yellow *Calceolarias*, and the furthest end pair Crystal Palace Scarlet *Geranium*.—D. BEATON.

MOORE'S "FLORAL MAGAZINE" for April contains plates of 1, varieties of *Clarkia pulchella*; of 2, *Pelargoniums*; 3, a very artistically executed plate of *Celosia cristata* (aurea), the yellow branching Cockscorn, which is now likely to be again cultivated; and 4, Carnations Rose of Castille, rose flake, and Pre-eminent, purple flake. We do not think that the former is at all flattered, it being a much fuller flower than represented in the figure.

FIG. 9.

TRAINING THE BRITTLE YOUNG SHOOTS OF VINES.

WOULD Mr. Fish in his papers, "Doings of the Last Week," or any other kind friend, inform *Clumsy*, how they manage to tie out the young shoots of their Vines? It invariably happens to him, that as soon as he touches one of them to bring it down to the wires that it comes out of the socket, and makes him stamp his feet and bite his lip in vexation, and bitterly bewail his extraordinary clumsiness.

The other day I thought these Vines wanted tying, "Just as the twig is bent," &c. First shoot got all right. Good! Well done *Clumsy*! Bravo! The very next—got hold of it as softly and delicately as possible, put the mat round it, pull a little. Hem, no need to pull any more, it dropped out. You may guess what a wry face I pulled. I gave over, put mat and knife in my pocket and walked away. I begin to think that I have the worst luck in the world, and that I am, indeed—*CLUMSY*.

[*Clumsy*, indeed! I do not believe a word about these thumb fingers as yet; but congratulate you on the crisp, healthy condition of your Vines, though that is no reason why you should break off their nice fruitful side-shoots in attempting to tie them regularly. Patience in such matters is a great jewel, and the shoot that will not come low enough at once, will come down after a time, when just a slight hasp is put on it to keep it from the glass. In such a case as yours, however, it would be best to lower the main stems of your Vines—say 3 inches or 4 inches, by swinging them to your rod or wire, instead of tying them to it, and this will bring all your shoots low enough to avoid any likelihood of breaking off when regulating them. I recommended this plan to some friends; but it was almost too good for them, for it made them so careless that they never tied out their side shoots at all, but allowed them to pop their noses up to the glass, and the weight of the fruit brought them gradually to the horizontal. This, however, was slovenly, if not "*clumsy*."—F.]

GROWING HORSERADISH.

THERE are many ways of growing Horseradish—we write in answer to "AN OLD SUBSCRIBER." It is always best when from one to three years old; for if the root is much older it becomes woody and hard, instead of succulent and juicy.

Now is a good time for planting it. It grows best in rich sandy loam, but is not very particular as to the soil.

The ground should be trenched at least from 18 inches to 24 inches deep. If poor, give a good coating of manure, and dig that into the bottom of the trench, but do not let it mix with the upper part of the soil, as that would encourage side rootlets. The ground being trenched and levelled, mark it out in rows 18 inches apart, and then make holes in the rows 12 inches apart, and 15 inches deep, and in these drop three-inch pieces of the crowns of old Horseradish plants, with the green part uppermost, or three-inch pieces of any part of the roots, with the top end uppermost. We have found them do equally well.

Then fill up the holes with a mixture of sandy loam and fine coal ashes.

Many of these will yield fine roots the first winter, but they should stand until the second, and not longer than the third winter.

To have Horseradish fine, a small piece of ground should be planted every year.

Though we have mentioned three inches as the size for plants, the smallest bit will grow, and many in taking up merely leave a piece in the bottom of the trench to insure successions.—R. FISH.

NICE, ITS CLIMATE AND PLANTS.

No. 3.

NICE, APRIL 1, 1861.—The past month of March is stated by residents to have been quite of an exceptional character. The mornings and evenings have usually been calm, with strong winds in the daytime. This year, however, winds have prevailed occasionally in the night as well as the day, sometimes rising in the evening and subsiding before morning. From the 25th of February to the 24th of March the weather was magnificent, only one shower of rain during that period, and nearly a cloudless sky, the wind generally from west, north-west and north. On the 25th the wind changed to the east, and since then a

good deal of refreshing rain (which was much wanted), has fallen. The temperature of the month has ranged from 42° at night to 62° in the daytime, the night average being 52°, and that of the day 58½° in the shade.

One great advantage of this place is the dryness of the atmosphere during the winter months, and it is rather remarkable that the summer months should be more humid than those of winter. According to scientific observations published for the last year, it appears that the highest hygrometric mean (taken by Saussure's hygrometer) was in the month of July 63°, and the lowest in the month of February 54°, the average for the year being 59°. The maximum 70° during heavy rain in December, and the minimum 37° on the 5th of March, occasioned by a strong mistral wind then blowing. A similar account, if it could be furnished by any of your correspondents as to parts of England, would be very interesting by way of comparison.

Our ordinary English summer Swallows have now made their appearance here in considerable numbers, and also the Martins. Handsome Swallow-tailed Butterflies, Red Admirals, orange and sulphur-coloured, with several others are becoming numerous. Grape-vine shoots are in many places 6 inches long, and showing the bunches; Figs are out in leaf, with young figs on the branches.

During the month the following wild flowers have come into blossom:—

- March 4. *Antirrhinum nicaense*, large yellow.
- " 6. *Lithospermum purpureo-ceruleum*, splendid blue.
- " 12. *Allium neapolitanum* (fine white-headed Garlic).
Symphitum officinale and *tuberosum*.
- " 16. *Polygala nicaensis*, fine blue.
- Iris pseudacorus* (yellow Flag).
- Chelidonium majus*.
- Coriaria myrtifolia*.
- " 23. *Ornithogalum umbellatum* (Star of Bethlehem).
Hyoscyamus albus (Henbane).
Cistus albidus (showy large Pink).
Muscari racemosum and *M. comosum*.
Leucojum tricolor (Snowflake).
- " 28. *Amelanchier vulgaris*, on the hills.

In the gardens and hedges are the China and other Roses, very fully coming into flower, and in most places looking very healthy, free from insects. Pear trees and Cherries were in full flower on the 19th, also Quinces and Elder on the 24th. A large white *Spiraea* (*grandiflora*) is very showy in the public garden; also Lilacs and tree *Præonies*, Honeyuckles, and Banksian Roses. *Vistaria consequana* (or *Glycine sinensis*), is in blossom on walls and standards. *Asparagus* is now quite common in the markets, also Green Peas and new Potatoes.

The Tomato is much more used in cookery in Italy than in England, and it is grown in considerable quantity for the purpose. The young plants are raised with but slight covering in the open air, and, having been transplanted once, are now nearly ready for setting out in their final quarters.

Oranges are fully ripe and sweet. The general crop has been gathered; but there are many yet left upon the trees, which are now showing blossom for this year's crop. In the course of the present month an Orange flower fair is held in the town. The flowers are quite an article of commerce, and are sold by weight (like hops in England), to the distillers for perfumery, as are also the double Violets, so extensively grown in this neighbourhood.—E. CORLAND.

DECAY OF CROCUS BULBS, AND THEIR PROPER CULTURE.

FINDING that you require to know the nature of the soil, and the mode of culture adopted by me, before you can express an opinion as to the cause of the decay of the parent Crocus bulbs after flowering in pots, I beg to say, that I employ ordinary garden soil mixed with about one-third leaf mould and a portion of silver sand. I drain the pots well, and surround the bulbs with silver sand alone. The pots are kept in a dark cellar for a month after planting, and are then removed to a greenhouse without heat, where the bulbs always flower abundantly. I leave them in the pots until the leaves are quite decayed, and on removing them, always find the original bulbs rotten, and four or five small ones formed.

On removing *Narcissus* bulbs, treated precisely in the same

way, I find each bulb divided into three or four small ones, which do not flower the next year.—H. A.

[Now the matter with your Crocuses is as plain to us as if we had all your bulbs before us. The best soil to pot Crocuses in is the top part of the best piece of ground in the kitchen garden, where it was heavily dunged the year before. No leaf mould, no peat, and no sand for potted Crocuses on any account whatever. It is good to put sand and mixture of soils with bulbs of all sorts in the open ground, and with most of them in pots; but the Crocus, and a score of other kinds of bulbs, are more easily grown under hard treatment, with nothing but good drainage, and a good top soil from a good kitchen garden. That soil has been often and well dunged, and dug, and aired, and mixed, and the excess of dung, or the rankness of it, has been naturally dealt with by the crops on it: therefore, the first four top inches of a piece of good kitchen garden soil are more safe for bulbs, whether they be forced or not, than any compost. The leaf mould and sand in your compost in pots for Crocuses made the soil so very open that in March and April it would need to be watered four times a-day whenever the sun shone; but probably you did not always water even once a-day, and you did right, for too much watering soil that is too open only allows the water to wash all the goodness out of the little balls, unless something good was in the water occasionally. You took more—much more, from your Crocus bulbs than you gave them, and the next year they needed a good fallow, a rest in good soil, and not crowded. The great secret in forcing Crocuses early is to have them in the pots between the first and fifth days of September; if they are potted after the 15th of September, they should not be forced early, or else they should be thrown away when the flowers are over as not good enough to nurse.

All forced Crocuses should be set in the open air as soon as the flowers are over, and in one week after that be planted out at once, *and not with the balls entire*, which is most hurtful to all bulbs so treated. Break every ball of all sorts of Crocuses into three parts at least; plant the roots just as deep as they were in the pots, and no more. Never disturb a forced Crocus, or any forced bulb under the sun, until it has had one season's growth out of the pots, and two seasons if possible; but Hyacinths require three seasons even in good hands.

A Crocus bulb, a Tulip bulb, and a Gladiolus bulb, and many others, never flower but once; then they die, and their offspring succeed them in offset bulbs. That was the natural cause of your finding dead bulbs in your mould.]

MANAGEMENT OF YEW AND OTHER EVERGREEN HEDGES.

I LAST year planted a good many Yews, intended ultimately to form a protection against the north wind. They are fine healthy plants, averaging about 5 feet high, very thick and bushy down to the ground, their bases being, perhaps, 6 feet in diameter. Now I do not care about this extreme thickness at bottom, but want to encourage them as speedily as possible to increase in height and thickness at top. Shall I do any good by cutting away a quantity of these lower lateral shoots? Several of the plants have no decided leader, but may almost be described as bunches of suckers. Shall I increase the vigour and tendency to upward growth of the main stems by cutting out the minor ones?—L. H.

[Your Yew hedge is just 4 feet too much through at the bottom. The best Yew hedge that we have seen was at Boyton, on the other side of Salisbury. It was 35 feet high, and not nearly so much through at the bottom as yours is at 5 feet. There is a natural law about cutting in the boughs of all kinds of evergreens, which can never be departed from in a single instance without doing more or less harm in the long run. It is this—that the lowest boughs all round the bottom of a tree or bush be left longer than those above them, if only the fraction of an inch, and the rule holds good from the bottom boughs to the topmost ones, even of a Wellingtonia. The reason for the rule is this:—If the boughs or branches in any part of the tree or bush are allowed to get longer than those below them, the longest will throw off the drops when it rains, and shade those below from the sun; and when the sun and rain are kept from an evergreen bough it soon languishes, and dies by inches. That is the only reason why Laurels and Fir-trees, and

all the rest of them, get naked below. People allow the top branches to spread over the bottom ones. Now, any one who understands that law, and acts on it, can never go wrong in managing a Yew hedge, or a Holly hedge, or a Portugal Laurel out on the lawn, or a Cedar of Lebanon, or a Juniper, or a Cypress, or any other such plants. The more leaders there are in a Yew hedge, or a Holly hedge, or a Thorn or Barberry hedge, or any hedge whatever, the better, provided that none of the leaders are allowed to get much stronger than the rest, which is secured by stopping, *in the summer*, any of the leaders which are much stronger than the rest.

About the young hedge of Yews which is 6 feet through at the bottom, cut off 18 inches of every one of the bottom boughs on both sides, and the hedge will then be only 3 feet through, and that is quite enough for a fifteen-feet-high hedge. Cut the next boughs a little shorter than the first, the third cut a little shorter than the second, and so on to the top, which at the height of 5 feet should not be more than 6 inches or 8 inches through, if so much, but that depends on the positions of the leaders. Now is the best time for this cutting. At the end of July, regulate both sides again by cutting back such shoots as get over your rule. For the next ten years the bottom should not be allowed to get much wider than the 3 feet. Meantime, Yews would take just as much dung and liquid manure as a bed of celery, and would pay for it much better, by growing three times faster than without that help, which is the only assistance that can be given. Yew trees planted singly will do all the better by having the first foot or 18 inches next the ground freed from branches, in order to let in a circulation of air; and all the leaders, except the strongest or best central one, should be stopped, and after that be kept in constant subjection. But the rule about having the bottom boughs the longest has not a single exception in the whole vegetable kingdom of evergreens. At the height of your trees, if they are single, leave 4 feet across the bottom, and allow only 2 inches more to extend yearly till the trees are 10 feet high; then 6 inches annually for the next six years; after that they will need very little to be done to them. But to get them up quick, ply then well with liquid manure of moderate strength. We planted five hundred miserable little Yews in 1855, in, or rather over, a solid bed of very good rotten dung, just as for a row of celery. They are now finer than your plants, and shine again, but they have had hogsheds of liquid manure.]

REMOVING THE DISAGREEABLE SMELL FROM GISHURST COMPOUND.

THE writer of the interesting article on orchard-houses in your paper of the 9th calls on the inventor of Gishurst Compound for "some agreeable disinfectant" to neutralise its smell. Will you allow me to inform him that by making his solution forty-eight hours before use he will find that the greater part of the smell has passed off? As to what remains, I fear it must be put up with. It is due to the combination of sulphur, to which Gishurst owes much of its efficacy.

Last year a fine pot Plum tree was given me as being incurably attacked by mussels scale. I dosed it over and over again with Gishurst lather worked up by a shaving-brush. The tree has now a fair show of bloom, and its former owner considers it cured; but though it is many months since the medicine was given, owing to its being used fresh some smell still hangs to the bark.—GEORGE WILSON.

CULTURE OF THE GRAPE VINE.

I HAVE been a grower of Grapes both as under and head-gardener for nearly forty years, and the culture of this fruit has always been a favourite pursuit with me. I may venture to add, too, that I have generally been a successful Grape grower. In the following instructions, however, I have not been guided solely by my own experience, but have gathered up information from most of the best Vine cultivators in the kingdom. As a traveller for many years in the nursery and seed business, I had, whilst performing a traveller's duties, the opportunity of calling at most of the best gardens and seeing the management of the Vine under the most celebrated gardeners, who, I can bear testimony, were always ready to give me any information I might ask for, as to the why and wherefore of their practice in certain

methods of culture, in order to obtain such fine fruit as I saw before me. I was also equally as anxious to find out the causes of any failures I met with, whether with regard to missing crops, shanking, spot, deficient colouring, or any other defect the Vines displayed. All these good and bad points of culture I have treasured up, and intend to lay before the reader; and if he pays attention to my statement on the subject, I think that he will be enabled thereby to so manage his Vines as to bring to perfection good fruit and avoid the failures too many have met with.

The Vine is an accommodating plant, easily grown, and very soon bears fruit. In this country it is grown against walls without any protection; in orchard-houses now so fashionable and so useful; in greenhouses over flowering plants; in stores over flowering plants and Pines; and, in what is by far the best mode, in houses especially erected for Vine culture, and hence named vineries. It is also grown to some extent to fruit in pots. On all these modes I intend to give my experience, adding the names of suitable kinds for each situation.

SOIL.—Without that is right, all the other adjuncts will be useless, however perfect they may be. Whoever, then, intends to cultivate the Vine should procure, a year beforehand, a sufficient quantity of the top spit of a meadow or pasture, choosing one the soil of which is neither light nor heavy. Bring away the turf and soil together, and lay it in a long ridge near to where it will be wanted. To every six loads of this maiden earth add one load of half-rotted stable-dung. Put this dung in thin layers amongst the soil equidistant throughout. To these add in the same proportion, half a cartload of old lime rubbish, bits of bricks, and such like; also, a good sprinkling of broken bones—say a quarter of a cartload to the other seven and a half loads of soil, dung, and bricklayers' rubbish. Lay the heaps so that the sun will have free access to every side, and in order to effect that the heap should run from east to west. Let the heap lay for three or four months, and then commence at one end and turn it over, thoroughly mixing the whole of the ingredients of the compost. Do not, however, chop it very fine, but leave it in lumps throughout, so that the air can penetrate into the centre of the heap as much as possible. As a matter of course, no weeds must be allowed to grow on the compost during the twelve months. Turn it over again in four months, and that turning will be sufficient till the Vine-border is ready to be formed.

Whether the Vines are grown in the open air on walls, or in houses, such a compost must be prepared for them.

DRAINING THE BORDER.—It is of no consequence whether the situation of the border is low or high, it must be drained. Stagnant water is injurious to the roots of any fruit trees, but more especially to the roots of the Vine. In low, level lands, the drainage should certainly be more perfect—that is, there should be a certain and sure outlet for the superfluous water, and the stratum of stones or brick ends should be thicker.

Let the bottom of the border be above the main drain, and sloping up to the wall. It should be either concreted or rammed down very hard. The drain to carry off the water should be bricked at the sides and covered with stoutish flags, so that, in case of any stoppage from silt or tree roots, it could be opened and cleaned out whenever it required it.

This drain having been made properly, and the bottom of the border made hard, then lay on the rubble evenly all over the border. In high dry lands this layer need not be more than 6 inches or 8 inches thick; but in low situations, even if the border of earth is raised above the level, the drainage ought to be at least 1 foot thick. If the Vines are planted in a border inside the house, that border should be drained also. Level the drainage and run a roller over it. Then, to prevent the finer parts of the soil falling into or being washed into the drainage, cover it over with thin turf, the grassy side downwards. All this being completed, the next operation will be wheeling in the soil. Lay substantial planks to wheel on, and fill it up at the far end to the required thickness, and so on till it is completed. There has been considerable difference of opinion amongst writers as to the depth of the Vine-border. Some recommend as much as 4 feet, others 3 feet, and some 2 feet. Deep borders are certainly very objectionable, because the deep stratum is often so cold and so far out of reach of sun heat. Perhaps if hot-water pipes were run across the border for the purpose of warming it, then a deep border might be useful. However, to be on the safe side I judge the border should be 2½ feet deep. It is the depth I have always made them, and every good grower that I know recommends that depth. The soil being all wheeled

in, the border is then completed. It should at first be 6 inches above the level intended, to allow for settling.

SECTION OF VINE-BORDER.

The accompanying section shows the drain to carry off the water, the rubble to keep the soil dry and the soil above it.

WIDTH OF THE BORDER.—For Vines growing against walls in the open air 10 feet or 12 feet will be sufficiently wide.

For Vineries, Stores, and Greenhouses.—The rule in general should be, that the border should be the same width as the rafters are long. Some good cultivators have adopted the practice of making the border a few feet wide the first year, and adding to it year after year until the Vines have reached the top of the house. Where appearance is of no consequence, such a plan may be advisable and worth a trial; but as most excellent Grapes have been grown where the border has been completed at once, that plan as a general rule may be regarded as at least equal to the other, and certainly for finish and complete neat appearance far superior; and, besides that, more main drains would be required which would be a needless expense.

There is a Vine-border in the garden at Heath Bank, Cheddle, near Manchester, across which are built brick walls, dividing it into as many sections as there are Vines in the houses. The reason assigned for this was, that each Vine could not encroach upon its neighbour's pasture; and also if by any chance a Vine failed, or it was thought desirable to plant some superior or newer kind, the soil could be all taken out of each division, and fresh put in without disturbing those left to grow. I have seen the Vines in that place, and they were very healthy and produced large crops of good fruit, but I never heard that one of them had been removed or had failed: therefore, the usefulness of this somewhat expensive border for the purposes for which it was divided into long brick pits has not been proved. Yet it may be worthy of a trial, especially in conjunction with a heated chamber to warm the border of Vines for forcing early.

T. APPELEY.

(To be continued.)

TRUFFLES.—Do any of the readers know if this singular production can be cultivated, and in what way? Not having had any experience in it myself, I am anxious to learn if it can be transplanted with any prospect of success. Growing deeply in the ground and amongst the roots of trees, it may assuredly succeed if planted in a similar place; but really little seems to be known about this fungus, except, perhaps, in the locality wherever it is grown. But if some one who has noticed its habits will favour us with his observations or experience, it is possible it might be introduced to other neighbourhoods similarly situated and possessing like advantages, and the obscurity or mystery which hangs over this singular article be removed. Any one favouring the readers of THE JOURNAL OF HORTICULTURE with a communication throwing light on the matter, will confer a benefit on them generally, and especially on—AN OLD SUBSCRIBER.

[We shall be much obliged by information on this subject.—EDS. J. H.]

SIX WREATHS OF FLOWERS.

WREATH THE FIRST.

"What fashion will you wear the garland of?"

SHAKSPERE.

WELL, the first shall be of various purple and blue flowers, for sympathising with our Queen—it is a season of mourning.

Let there be *TROPEOLUM DECKERIANUM* from the conservatory, with its downy twining stem, peltate, sinuate, ovate leaves, and its flowers of mingled blue, scarlet, and green.

Let us dwell upon this a little longer. The spur of the flower is scarlet tipped with green, and the five short, wedge-shaped petals are intensely blue. The stems, like those of the Ivy, emit rootlets. It may be grown out of doors in summer, being cultivated in a pot, and trained like other small species of the genus. Its roots are fibrous, and it may be propagated either by seed or cuttings—at least, so says Van Houtte; and he further records that it is a native of Venezuela, whence it was introduced to the Botanic Garden at Berlin, about the year 1849.

As we have been asked "Why Linnaeus applied the title *Tropæolum* to this genus?" we may as well answer here, that when that great classifier of all things natural took upon himself to apply brief names to all the vegetable world, he must often have been sorely perplexed for an appropriate designation. Nor was this genus an exception. He had before him only two species—the large and the small Indian Cress, popularly called *Nasturtiums*; and he fancied, we suppose, in the flowers he saw a resemblance to the helmet, and in the peltate leaves to the shields, of which the Greeks constructed their trophies. We must rub up our classic lore to explain that the *Trophaion*, or Trophy, of the Greeks, was a pile of arms and armour erected by them on the spot where their enemies' flight commenced, *trophè* being literally a turning about. At all events, Linnaeus called these plants *Tropæolums*, or little Trophies, and we cannot but think he might have found a more appropriate name if he had called to mind what our old herbalist, Parkinson, wrote about them. "Some doe reckon this plant among the Clematides or Convolvuli, the Clamberers or Bindweeds, but it hath no claspers, neither doth it wind itself. Monardus and others call it *Flos sanguineus* (Bloody flower), of the red spots in the flowers, as also *Nasturtium indicum*, by which name it is now generally called, and we, thereafter, in English Indian Cresses, yet it may be called from the forme of the flowers only *Yellow Larkes-heeles*."

We must pass on to the next flower in our wreath, and it is *DIPLADENIA ATROPURPUREA*, a beautiful climbing or twining plant for hothouse culture, introduced from Brazil in 1841 by the Messrs. Veitch. It is slender in stem, with dark, shining, evergreen, pointed-elliptical leaves, and flowers of a deep clarett purple colour. The tube of each flower is about 2 inches long expanding conically into a wide throat, and a widely-spreading limb fully $1\frac{1}{2}$ inch across. When first expanded they are agreeably fragrant. Miugled with the flowers of *Stephanotis floribunda*, and *Echites sub-erecta*, the Savannah Flower, Sir Joseph Paxton suggests that they would form beautiful wreathing for the trellis-work and pillars and rafters of the stove. It reaches to a height of 10 feet and even more. Sir Joseph has stated that it may be grown either in a large pot, or in a compartment of the stove-border, in a mixture of sandy loam and heath mould, well drained, and only moderately supplied with water. The stems being weak require pruning in winter, and the side shoots may be improved by stopping during their growth. Two or three years elapse before the plant acquires the ornamental character it really possesses. It then begins to blossom early in July, and produces a profusion of flowers from the axils of the leaves throughout the summer. It is easily propagated by cuttings of the young wood.

Dipladenia is a genus formed by M. Alphonse De Candolle from various species separated from the old Linnæan genus *Echites*. He named the genus in allusion to two tubercles or glands produced at the base of the ovary, from *diplos*, double, and *aden*, a gland.

The third flower in this wreath is *ONCIDIUM COSYMBEOPHORUM*, one of the prettiest of Orchids, with its petals and sepals brightly rosy, spotted with purple, and tipped with yellow; the lip is cinnamon, and the tubercles at its base purple and yellow.

It is on these characteristic tubercles that Swartz founded the name of the genus, *Onkidium*, a protuberance. The specific name, literally "the tassel-bearer," alludes to the form of inflorescence, and is derived from *kosymbos*, a tassel, and *phora*, the act of bearing.

The native country of this species is not known. It was introduced to the Belgian gardens about 1848. It flowers in August.

ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE.—The season must be still telling on the exertions of growers; for although there was a pretty display, yet not so much as one might have expected at this Meeting. A collection of stove and greenhouse plants was, however, forwarded in good condition by Mr. Veitch, of Chelsea; and a small one of Auriculas by Mr. Turner, of Slough. For each of these a Special Certificate was awarded. The former contained well-grown and fully bloomed plants of *Azalea indica*, Queen Victoria, Duke of Devonshire, Princess Mary of Cambridge, Delicatissima (a fine white, blotched and spotted with crimson), Elegantissima, Bicolor, Roi Leopold (a fine thing both in colour and shape), Iveryana albo-cincta and Madame de Rothschild, *Ardisia crenulata* and *Erica hymenalis*. The stand of Auriculas consisted of Souter's Waterloo (green edge, a very circular flower), Conqueror of Europe (grey edge, large and fine), Martin's Mr. Sturrock (crimson self), Hogg's Waterloo (rough and coarse), Dickson's Matilda (green edge, fine truss, and of beautiful colour), Taylor's Glory (fine white edge), Masters' Myfield (pretty blue self) Traill's General Niel (good, green edge), Lightbody's Meteor Flag (good, blue self), Dickson's Duke of Wellington (too full of colour), and Maclean's Unique (fine, bold grey edge).

Amongst the objects sent in for the decision of the Committee was *Campylobotrys refulgens*, a beautifully ornamental-foliaged plant from Chiako, in Mexico, sent in by Mr. Bull, of King's Road, Chelsea: for this a First-class Certificate was awarded. The same gentleman sent *Citharoxylum niveum*, or the Silver Palm, also from Mexico; but the Committee did not consider it to be sufficiently developed for its merits to be judged at the present Meeting. From Mr. Turner, of Slough, came Auriculas Volunteer and North Star, which have before been rewarded by the Committee, and were considered to have sustained their character. Also Rileman, too coarse, and Negress, too rough, to be of any value, and a fine grey edge; the Rev. George Jeans, somewhat of the Conqueror of Europe strain, but very excellent and deserving of the label of Commendation it received; also *Cinerarias Reynolds Hole* (coarse), and Miss Eyles (very pretty and free-flowering). A First-class Certificate was awarded to Mr. Kinghorn for his *Azalea Kinghorni*, of great substance of petal and fine form, though somewhat dull of colour. *Epacris rosea*, from the same gentleman, was not considered good.

Messrs. F. & A. Smith, of Dulwich, received labels of Commendation for two free-flowering, early-forcing *Geraniums*—one a warm orange rose, called *floribundum*; the other a good white snowdrop. As these will evidently force well, they will be very valuable for market purposes and decoration. Messrs. Parker & Williams, of Holloway, sent a pretty free-flowering *Statice*, called *propinqua*. It was too similar to one named *profusa* to be considered worthy of Commendation, and it was suggested that they should be compared together. Mr. Salter, of Hammersmith, sent in some variegated plants—*Symphytum officinale*, the common Comfrey, and *S. tuberosum*, the tuberous Comfrey. For this a label of Commendation was awarded; as there was also for *Veronica chamædrys*, the common Germander Speedwell with variegated foliage—likely to be useful as a rock plant and for edgings. Messrs. Veitch & Son also received a label of Commendation for *Epacris Vesta*, white with pink tips, a pretty and free-growing variety. Some ornamental-foliaged plants, contributed from the Society's gardens, tended to make a nice display in the room.—D.

FRUIT COMMITTEE.—A Meeting of this Committee was held on the 9th inst., C. Wentworth Dilke, Esq., V.P., in the chair. A basket of very excellent Black Hamburgh Grapes, highly coloured, and well covered with bloom, was exhibited by Messrs. Spary & Campbell, Queen's Graperies, Brighton, and a Certificate of Commendation was awarded to the exhibition. Messrs. Wheeler & Son, of Gloucester, sent a dish of Ashmead's Kernel, a delicious little dessert Apple at this late season, and the sort was greatly admired; a full description and figure of this variety were given in our last week's Number. Mr. Rivers brought a

dish of Mela Carla—a delicious Apple of Italian origin—which requires a wall, or the shelter of an orchard-house in this country, to bring it to perfection. The specimens were very fine, but rather over-kept, as they had begun to get mealy; but they had the fine peculiar flavour and aroma that characterise that variety.

Mr. Cole, gardener to Mrs. Silver, Abbey Road, St. John's Wood, exhibited a nice collection of Apples, which was awarded a Certificate of Commendation for the excellent manner in which they had been kept. Among them were Kerry Pippin and Ribston Pippin; both, however, without flavour, but well kept. A dish of very excellent Elruge and Pitmaston Orange (misnamed Hunt's Tawny), Nectarine was received from Mr. Gardiner, Eington Park, near Stratford-on-Avon. Their flavour was excellent, and as they exhibited great skill in having been produced at so early a period, a Certificate of Commendation was awarded to them. Mr. Cant, of Colchester, exhibited excellent specimens of Blenheim Pippin, and a sort called Spice Apple, which was uncertain in flavour, and was requested to be sent again another season. F. J. Graham, Esq., of Cranford, brought specimens of Bedford Pippin, an excellent late dessert Apple raised at Bedford, but this season it is not equal in flavour to what it usually is. Mr. Graham read an interesting paper upon an insect which infests the fruit of the Pear, and which is supposed to be hitherto undescribed. Provisionally, Mr. Graham called it *Musca Pyri*, as it belongs to the tribe Muscidae. The thanks of the Meeting were given to Mr. Graham, and the paper ordered to be published in the "Proceedings."

DANDELION AS A SANATIVE.

IN consequence of Mr. Hardy's suggestions last year in your valuable paper respecting the use of the Dandelion as a salad, having acted on his benevolent advice, I can say that it is the best alternative diet used; but I find that late in the summer the plant is not sufficiently crisp to be easily masticated. Will he, or some other kind contributor of yours, be so good as to give some instruction, so that its texture may be made more agreeable during summer and autumn? I would prefer having my medicine-chest in my own garden; and I believe the value of the Dandelion requires only to be more generally known to be extensively used as a substitute for other salads.—J. L.

[Your correspondent "J. L." justly complains of the toughness of the Dandelion leaves for mastication in summer and autumn. In fact, they are not so sufficiently crisp then as could be wished for—especially for aged persons who have lost their teeth—except they are bleached as lettuces, endives, chicory, &c. In summer they should be in a shady compartment of the garden; but if they are frequently cut off, young tender sprouts will soon re-appear—it may be, several times in a season. They are acknowledged by most people to be more agreeable to the palate (not so bitter) chopped fine, and mixed with lettuces; and I for one relish them best with vinegar and sugar with only plain bread (not new).

To bleach them, however, which renders them more tender, various plans may be devised and propounded by other correspondents, which will assist the inquirers of your valuable Journal. My own directions are to take the roots up in autumn, or even in spring, and place them in a dry and dark cellar; or the gardener may place them in a spare darkened corner of his tool-house, or greenhouse, covering them slightly with leaves, dry mould, or coal ashes. They will thus bleach nicely and be crisp, and will be accessible at all times, even in winter, when the leaves cannot be obtained abroad. The coarse leaves which I recommend to be frequently cut off need not be wasted; for either they or the roots, separately, or both together, may be roasted in a small oven, and these, if powdered or broken small, will make an excellent and agreeable beverage as a substitute for coffee; and still better if mixed with it instead of chicory.

In short, use Dandelion how we will, it will be found an excellent restorative for cases of liver complaints, lowness of spirits, indigestion, and many other disorders following in train from a torpid liver. That it restores the appetite and braces the nerves, I my humble self can give ample testimony. A gentleman friend of mine assures me that his sister makes excellent "beer," sparkling and nourishing, with the decoction of roasted Dandelions. Finally, I can speak positively to the good effects from them, and have many testimonials of their good medicinal properties, both from the leaves as a tea and a decoction of the roots, or of either.

Note, as a salad it should be eaten only with plain wholesome stale bread, and not with bread and butter, or greasy meats—these things only indulge the appetite. Moreover, strong drinks also counteract the medicinal properties of Dandelion, if not of all other food in no small degree. Pure water which has been boiled is all that is really necessary to be drunk (barring medicines properly administered in small and frequent doses) for the sustenance of man, and to invigorate his strength, and prolong his life.—A. HARDY, *Seed Grower, &c., Maldon, Essex.*

FUMIGATING WITH TOBACCO-SMOKE

A GREENHOUSE COMMUNICATING WITH PARLOURS.

"F. G. H." would be much obliged by the Editors informing him how effectually to smoke a greenhouse infested with green fly. The greenhouse is 30 feet by 9 feet, a lean-to, and two sitting-rooms opening into it.

"F. G. H." is very anxious to know how to keep the smoke from entering the rooms. He has nailed up carpets and sheets without effect; and last night he nailed up against the doors (double doors of plate glass), wet blankets, but these did not keep the smoke out. He uses a portable stove and a pound of Coventry tobacco paper. This the gardener blows with a pair of bellows. It takes him five minutes, and the greenhouse is then full of smoke; but also, unfortunately, in ten minutes after the sitting-rooms adjoining are redolent of tobacco-smoke, and, worst, of all, the fly is not killed in the morning. The plants are too numerous to move if he had another house to smoke them in, which he has not; and this smoke entering the house is an insuperable objection to a greenhouse again being attached to the house, if it cannot be prevented entering it.

[In such a place we would prefer the best shag tobacco—say six ounces at one time, and repeat the dose three nights afterwards; but we can offer no practicable suggestion, under present circumstances, how the smell of the smoke can be excluded from the rooms. In all such cases the plants, whenever one or two are infested, should be moved out. If you have a spare room, or a close shed about the place, we would undertake to clear the plants out of such a house in no great time and smoke them there; but the great thing is to prevent a general smoking by taking a plant out as soon as a fly is seen on it, and, having a rough box knocked up which you can keep for smoking purposes, smoke that plant at once. This is by far the most economical plan. Our box is about 4 feet in height, 5 feet long, and 4 feet wide, with a hipped roof, and we have moveable shelves in it for small plants. We either burn the tobacco in it in a flower-pot, or insert the tube of the fumigator through a hole in the door. We have two or three squares of glass laid in on the top, that we may see how the smoke goes on without opening the door. With a little contrivance any old box, packing-box, &c., might be turned into such a smoking-house, and all smell in the sitting-room avoided. A small pinch of tobacco will do in such a place. If the plants are not extra large, the whole from such a house might soon be smoked in turns. Any small close shed or room would just answer as well, only the larger the place the more the tobacco needed. The great thing in smoking is to prevent the smoke reaching the plants in a hot state. If you still object to the smell of tobacco smoke, try killing the green fly by syringing with Gishurst Compound. This has a disagreeable smell, but you will see to-day how the manufacturer of the Compound says that smell may be removed.]

CUCUMBER PLANTS NOT PERFECTING THEIR FRUIT.

Will you oblige "J. B." by informing him why Cucumbers will not swell off? The fruit shows at every joint and grows to the length of 5 inches or 6 inches, and then goes off. He keeps them to a regular heat of 70° by night and 80° by sunshine. "J. B." has grown Cucumbers for fifteen years, and never saw the like before. No plants can look more healthy.

[Let your temperature fall to 65° at night, or even a few degrees colder by leaving air on, and keep the plants rather thin of leaves and shoots. More sap then will be thrown into the fruit. See, also, that the bottom heat is not too strong—not above 85°. We hope the above will help you, but some of the best gardeners could not get Cucumbers to swell last year, as Mr. Fish has stated.]

POMOLOGICAL GLEANINGS.

GROS MAROC GRAPE.—This is likely to prove a valuable new purple Grape. Its berries are oval and very large; bunches shouldered and very large. Its habit is most vigorous, with large woolly leaves. It ripens with the Black Hamburgh in a house without fire heat, and will hang a long time on the Vine, or be kept with great ease in bran, so as to form English Raisins (as mentioned by our correspondent "R."), as its skin is thicker than the Black Hamburgh. Its flavour is remarkably rich.

GROS COLMAN GRAPE.—This is a round purple Grape with very large berries and bunches. Its leaves are large, and its habit coarse and most vigorous; skin thick and flavour inferior. It is, however, a very showy Grape, and like all thick-skinned Grapes it will hang a long time on the Vine.

MUSCAT TROVÈREN GRAPE.—A variety of the White Frontignan with very large berries and bunches. Though the flavour is less rich, it promises to be a very desirable sort.

EFFECT OF DRAINAGE ON GRAPES.—I have always noticed that here in Missouri wherever the Grape succeeds, it is upon land that has thorough natural drainage; and if any part of the vineyard is in a spot so situated as not to have good drainage, the Grapes will generally rot while the balance of the vineyard is perfectly sound. We can also see the same thing exemplified by noting the results of different years, and I think this has been one of the best to prove my opinions to be correct; for while in ordinary seasons more or less Grapes are affected by the rot, this year they have been totally exempt therefrom, and the reason is evidently the unusual dryness of the season and but very little dew having fallen after the 1st of June.—(*American Gardener's Monthly*)

ORCHARDING IN CALIFORNIA.—In 1858 we sold 480,000 lbs. of fruit, mostly Peaches and Nectarines. Our nett profits were about 50,000 dols. In 1859 we sold as follows:—Peaches, 841,300 lbs.; Nectarines, 121,000 lbs.; Apricots, 25,000 lbs.; Grapes, 25,000 lbs.; Apples, 15,000 lbs.; Pears, 5000 lbs.; Quinces, 2500 lbs.; Plums, 1000 lbs.; Cherries, 200 lbs.; Figs, 474 lbs.—total, 1,046,475 lbs. The fruit netted about 8 cents per lb., 79,000 dols.; gross 100,000 dols. This year (1860) we have sold about 2000 lbs. of Cherries, at 60 cents per pound; 2000 lbs. of Plums, at 60 cents per lb.; 40,000 lbs. of Apricots, at 20 cents per lb.; 3000 lbs. of Apples, at 25 cents per lb. We have yet to pick 10,000 lbs. of Apricots, 100,000 lbs. of Apples, 10,000 lbs. of Plums, 800,000 lbs. of Peaches, 100,000 lbs. of Nectarines, 30,000 lbs. of Grapes, 800 lbs. of Figs, 3000 lbs. of Quinces, and 6000 lbs. of Pears—total to pick, 1,057,000 lbs.: picked 47,000 lbs.; total, 1,104,000 lbs. This orchard contains about 40,000 trees.—(G. G. BRIGGS in *California Farmer*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

As soon as the seed-leaves of Cabbages, Cauliflowers, &c. appear above ground sprinkle soot or wood ashes over them for the purpose of preventing the attacks of slugs, &c. It should be frequently repeated until the plants are 1 inch or 2 inches high. **Beet**, sow a full crop of the Red towards the end of the week. **Capsicums**, repeat the plants of the larger varieties intended for turning out next month. **Cardoons**, the seed may now be sown in trenches where the plants are to remain; the trenches to be 4 feet apart, and a few seeds dropped in at intervals of 18 inches or 20 inches. **Cucumbers**, keep the shoots regulated, as on this particular their fruitfulness will in a great measure depend. **Mushrooms**, in making beds to produce through the summer a portion of loam should be mixed with the dung: this will give greater solidity to the bed, which will in consequence produce more fleshy Mushrooms. **Marigold**, sow, where it is required for kitchen purposes. **Nasturtiums**, sow some seed in any out-of-the-way place where the plants can do no injury by their rapid growth. They will be useful for pickling. **Peas**, continue to earth up, and stake them. After staking, the ground to be forked up between the rows, and where **Spinach** intervenes it will also be benefited by the operation. **Rhubarb**, sow seed. **Turnips**, make another sowing, to succeed those sown in the middle of last month.

FLOWER GARDEN.

Thin out early-sown annuals in open borders, leaving from four to six plants in each patch. The scythe will now be required upon the lawn once a fortnight. See that the directions

in the late Calendars are brought to a close as speedily as possible; for a busy season is fast approaching for the performance of other operations which should not by any means be interfered with by work which ought to have been finished a month ago. Sometimes the action of the wind on the flower-stems of Tulips will cause a cavity in the soil immediately around them, such to be carefully filled up, and the surface of the bed to be kept free from cracks and weeds. Propagate Pansies from slips and cuttings. Make another sowing of Sweet Peas, to keep up a succession of bloom. Climbing annuals—such as the Canary Creeper, *Convolvulus major*, *Cobæa scandens*, *Ecermocarpos*, *Maurandias*, *Lophospermum*, &c., to be sown in pots two or three seeds in each, and when strong enough to be planted to cover trellises, rustic work, &c. Some of these required to be sown early as previously directed.

FRUIT GARDEN.

Remove all the foreright shoots from Apricot trees, also a portion of the side shoots; but endeavour to distinguish those that are likely to form short fruit-bearing spurs as being the best to retain. Early and frequent attention to be given to the disbudding of fruit trees; for, if neglected, there is a probability of being under the necessity of taking off more shoots at one time than is proper, by which such a check is given to the flow of the saps as to cause the fruit to stop swelling, and eventually to drop off. Disbudding is the art of preventing the development of useless buds at the expense of those that should be preserved; it must be more advantageous to check an unnecessary shoot at an early stage than to wait until it has exhausted the tree of a portion of its sap, and then to be removed at the period of its full development.

STOVE.

The plants here are now progressing fast, and will require attention in shading during bright sunburst, and gradually increasing the humidity of the house to keep pace with the increase of solar heat and light. If creepers are trained under the rafters a little management in regulating them will save much trouble with the external shading, and add much to the internal appearance of the house. See that *Thunbergias* and other such pretty climbing plants have plenty of pot room, and trellises applied.

GREENHOUSE AND CONSERVATORY.

Camellias that are now freely growing to be supplied with an increase of heat and moisture, and to be slightly shaded in bright weather with thin canvases or netting. Stop in good time any strong young shoots of Orange trees. Pelargoniums to be staked and tied out. Give to the plants set with bloom-buds a little clear liquid manure occasionally, with a liberal share of growing room on every side. The young stock to be shifted forwards as they may require for a succession. Plants that have been growing for some weeks, particularly young ones, will now require to be stopped, more or less, in order to make them bushy. No sticks to be used to give form to a plant that can be managed by pruning and stopping.

FORCING-HOUSE.

Another successional sowing of *Amaranthuses*, *Balsams*, *Cockscombs*, &c., to be made, and those previously potted to be encouraged to make a vigorous and sturdy growth.

PITS AND FRAMES.

As the planting-out season approaches take every opportunity of hardening off the entire stock, that the change to complete exposure may be gradual. Attention to be paid to the timely stopping of straggling growth in order to have bushy plants. Turf or temporary boarded pits covered with double mats are very useful at this season of the year.

W. KEANE.

DOINGS OF THE LAST WEEK.

Sowed *Parsley* in a well-aired border, in rows 15 inches apart, and covered with light soil. Sowed *Spinach* between rows of Peas. Peas planted out are doing well. Those first sown in the open air are doing only so and so, which caused me to sow some, even of the Marrows, in boxes, and plant them out when 2 inches high or so, which are looking well. In such cold, wet springs, it is a point gained to get the ground extra sweet; and though the transplanting takes extra time, I believe the produce is earlier and better, and seed is saved. Thinned

Turnips and *Lettuces* sown under protection, and made the first sowing of Turnips in the open air. From this time until the last autumn-sowing of Turnips, we sow Turnips and Radishes always together, making the shallow rows 1 foot apart, and sowing Turnips in one row and Radishes in the next. The Turnip-rows are, therefore, 2 feet apart, and the Radishes are either used or pulled out of the way by the time the Turnips need all the room. Sometimes our chief of the kitchen will be content, in early spring, with white Turnip Radishes instead of early white Turnips, which is a great advantage, as for different purposes the difference can scarcely be detected, and Radishes may be easily had several weeks before Turnips. A nice little Turnip in May I always consider to be worth 6d. Turned, chopped, and dug ground in readiness for Carrot seed. Planted *Garlic* and *Eschallots*, late enough. Pricked out young *Lettuce*, and put pots that had grown Potatoes, now emptied, over *Sea-kale* in the open air, and placed a little litter over them to exclude the light. The heads covered a fortnight ago, are now coming nicely. Removed old sashes from earth-pits over Potatoes, Geraniums, and so forth, and substituted some Nottingham netting, as it will not be used for the walls this year, unfortunately.

Removed *Strawberry* plants when done fruiting from the different houses, and took them altogether from the Vine-pits, as the watering tended to make the pits too damp, as the fruit of the Vines was setting. Strawberries on the whole have produced most abundantly—better than I expected from the size of the plants, fully proving that, provided the buds are fairly ripened, the mere size of the plants is of less consequence. For many years I used to have for the main crop one plant in what is called a 32, or a six-inch or seven-inch pot; but this season, owing to the smallness of the plants, I used two for that size, and I should almost be inclined to do so again as they have done so well. On the other hand, there are still some left of Keens' Seedling, single plants, in 48-pots, which I like for early work, which have been and still are great pictures. With these I generally succeed well. I have friends who succeed better than I have ever done with Prince of Wales, British Queen, &c. Were a tradesman sure of the market, a fine sum of money might be made from Strawberries at from 1s. to 2s. per ounce. It is a good thing for gardeners when their employers patronise Covent Garden at this season of the year. If they never do so, they are very likely to use a basket of Strawberries in March with as little consideration as to how their gardener provides for them, as if they were supplied with a similar dish at the end of June. It would often tend, too, to put a stop to the cuckoo cry, "Oh! I get nothing from my garden in comparison to the outlay." Thinned the Sweetwaters in Vine-pits, removed plants from first vinery, thinned out Fuchsias, &c., in the second, and placed in the shade beneath the Vines *Achimenes* fresh potted.

For want of room placed these in six-inch pots for the present. They always do best when sprung in boxes or pans previously, for then you can single out plants of similar size, or, if anything, the highest and strongest for the centre, and using six or eight plants for such a sized pot, and potting again if deemed advisable. *Gesnera zebrina* treat in the same way. Shade and keeping the foliage dry are the chief elements for securing fine foliage; and the shade of Vines is just the thing for it, as after the Vines show flower it is rarely they ever see the syringe afterwards. The large Fuchsias have been moved to the late vinery, and placed on the ground near the back, with shelves of Strawberries, &c., above them. To prevent any check to the forward Fuchsias, less air is given at the back of the house, and this also helps to bring on the Strawberries; whilst by admitting plenty of air in front, the Vines that are tied longitudinally there will be kept cool, and so will the Pelargoniums on shelves and platform, before being moved to the conservatory. Gloxinias repotted and growing were placed in vinery under shade of the Vines. Camellias and Azaleas need more water on fine days; and Pelargoniums, &c., must be guarded against green fly by smoking. A few were affected before being noticed. Moved lots of seedling annuals in pots into a colder place under glass, that they may be kept stubby before being thinned into patches; also Tomatoes, Camellias, &c., to be treated in the same way. And among the flowering annuals such climbers as *Cobæa scandens*, which must be potted singly; various *Convolvulus*, and *Tropeolum pelerinum*, and others, and Castor Oil plants, chiefly for fine foliage. I sow few annuals out of doors at once, unless short-lived ones in patches, as *Collinsia bicolor*, the prettiest *Godetias* and *Cenotheras*, &c., and of all modes of sowing these and annuals in general in the open ground, in patches, I prefer placing a garden-

pot over the patch until the seedlings are up, and removing the pot first partially and then altogether during the day, and then covering up at night for a time until the weather can be depended on. When I sow rows out of doors, it is chiefly low-growing things, as *Saponaria calabrica*, *Venus' Looking-glass*, *Venus' Navelwort*, *Silene pendula*, *Sweet Alyssum*, *Mignonette*, *Virginia Stock*, &c. These will come thick enough, and be kept on with a little pruning; but for all taller things intended for beds or ribbon-lines, such as *Prince's Feather*, *Chrysanthemums*, *Marigolds*, &c., and even beds of such things as *Saponaria*, I prefer sowing in rows under protection, and then lifting and planting in patches. The extra labour is more than repaid by the extra satisfaction of regular lines and even beds. It was partly for this purpose that we moved the old ashes from the earth-pit of Potatoes; but chiefly for planting out *Verbenas* that we wish to forward in strength. A bed is made on the ground with about 9 inches of dung and leaves, about 6 inches of warm leaves go on the top of that, then 3 inches of rotten leaf mould, and then 2 inches or 3 inches of compost of sandy loam and leaf mould. A pole or young tree of spruce or larch, which we keep from year to year for such a purpose is laid on back and front, and on these the ashes are laid, and in a few days the bed below is in fine order for anything, as to pricking out, planting or sowing. We generally use an earth-pit for the purpose, and run a breadth of calico along. Plants lifted from such a bed in patches hardly ever feel the moving, and there they stand until you want them, and go into the ground just when in the best position for them. This and similar earth-beds will be sown or planted next week, and but for such simple contrivances we should never know where to put seedlings. Were it not for the want of heating material, I should apply the same modes to many things besides flowers and the earliest vegetables. It is of little use standing sucking our thumbs in the corners of our mouths like babies, or, sage like, tickling the inquisitive-bump behind the ear with one finger or even with two, if nothing came forth from such operations. Thousands of pots of seedling flowers are lost, because they neither get air enough, nor are watered properly, nor by timely pricking out are prevented "in the struggle for life" killing each other. Thousands of packets of seeds are sown every year in the flower-borders, and only a small per centage rewards the cultivator, and loud and deep are the complaints against the rogues of seedsmen, who sent out the *very best samples*, but could not manage to guarantee against the mismanagement and carelessness of the cultivator in sowing at improper times at unsuitable depths, in cold unaired soil, and who take no pains to prevent slugs, snails, and other vermin clearing off every vestige of seedlings as soon as they reached the surface. Try this month with all small and rather tender seeds, such a bed as I have mentioned, sowing in rows—say 5 inches apart, and tell me at the end of the season if the plan is not worth the cost of this Journal for a twelvemonth.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

HYACINTHS GROWN IN WATER (F. M.).—No treatment will induce these to bloom again next year. Planted in good rich soil, and protected in winter, they will bloom again, though not strongly, in the spring of 1863.

SUBSTITUTE FOR GLASS (S. W. S.).—Use tiffany, and dress it with the following composition:—Old pale linseed oil, 3 pints; sugar of lead (acetate of lead), 1 oz.; white resin, 4 ozs. Grind the acetate with a little of the oil, then add the rest and the resin. Incorporate thoroughly in a large iron pot over a gentle fire; and, with a large brush, apply hot to a fine tiffany stretched loosely previously, by means of tacks, upon the frame. On the following day it is fit for use, and may be either done over a second time, or tacked on tightly to remain. The quantity made according to this recipe will be sufficient for about 100 square feet of tiffany.

PAXTON'S CHEAP GLASS HOUSE (S., Halifax).—The maker advertises in our columns to-day.

BACK NUMBERS, &c. (A Gardener, Laverstoke).—You can have the Parts and Indices, as well as cheap covers for the volumes. You had better write to our office stating precisely what you require, and giving your full direction.

KIDDEAN SYSTEM OF HEATING (Adele).—Your way of reconciling the conflict between the Kiddean and Polmaise systems, by closing the ventilator over the front of the fireplace, and getting the draught from the ventilators on each side of the fireplace near the bottom, is well worth

knowing. It is too late, now, to attempt what you propose for Mr. Kidd; besides, he is gone to Scotland to arrange and lay out flower gardens for the Marchioness of Breadalbane at Taymouth Castle, and may be absent for some time yet.

MOISTURE IN THE AIR OF A CUCUMBER-HOUSE (An Essex Amateur).—If your four-inch pipes are closed properly at the joints the evaporation that comes from them would not damp a midge's wing. Your reasoning proceeds entirely on wrong data. In its natural habitat, in the hottest weather, the Cucumber grows in an atmosphere abundantly supplied with moisture. You grow the Cucumber in enclosed air, and at a season when our atmosphere is cold and most devoid of moisture. The heat from your pipes increases the evil, as the hottest and moistest air will ever have a tendency to rise and escape, and the cold and dry air to enter to supply its place. We can imagine, and have seen cases, where the leaves of the Cucumbers curled and shrivelled, because the dry air absorbed all moisture out of them. To remedy this, the walls are kept moist, the soil is kept moist—moister than otherwise would be needed—and syringing is resorted to; but the simplest and most effectual means is to place evaporating-pans on the pipes, which will give out moisture in proportion to the heat. There are several papers on this subject in late volumes from Mr. Fish and others.

HOTBED OF SPENT HOPS (R. Tazer).—Throw the Hops into a heap to draw off the extra moisture, and to cause the rank heat to pass away. If the weather be windy, cover the heap with a little straw or a mat. In a week or so, the Hops will be fit for use, and from 15 inches to 18 inches deep will be enough for what you require at this season. Add a few inches more, however, if you have them, because in very cold weather you may need the heat, and in fine weather you can give more air, and if necessary lift the pots, if you sow in pots, and set them almost on the surface instead of plunging them.

CONVERTING A HEN-HOUSE INTO AN ORCHARD-HOUSE (A Subscriber).—We cannot answer you as we would wish without data. We know nothing of the height of your house, the width, or the height of wire you propose having in front. The having a flue takes your house out of orchard-houses, and makes it a hot or forcing-house. With wire sides, the heat from a flue would be like pouring water in at a bung-hole and leaving the tap open. If there were not much of it it might be covered as you suggest, but would not glass be cheapest in a few years? We can judge that the proposal for ventilating will do, though it would be better made of glass in small frames; that the brick floor will do all well enough, and keep your roots from getting down; the earth should not touch the flue if you wish to get all the heat from it, and the trees must stand free of each other whatever the size. You had better have a Peach against the wall instead of a Green Gage; the latter will do better in a pot, so as to be exposed in autumn.

SEED FROM PENANG—DESFONTANESIA SPINOSA (E. X. M.).—We cannot be sure about your seedling, but think it may be a *Menispermum*, the seed of which is a drupe-like berry, rather larger than Indian corn, and the ovule inside is of a horseshoe or moon-like appearance, and hence the name *moon seed*. Most of them are hardy creepers, running over sticks and fences quickly; but as yours came from Penang it may probably be planifolium, and, therefore, will require either a stove or warm greenhouse. It is hardly worth the space it will occupy, but we cannot determine satisfactorily. Let the *Desfontanesia spinosa* grow on in the greenhouse in summer, and give less water and as much sun as possible in autumn, and keep it rather dry in winter. If you send two postage stamps and your direction to our office we may be able to supply the Index.

WARTED VINE LEAVES (Grape Vite).—The warted appearance on the under side of your Vine leaves is produced chiefly by too much moisture in the air of the house, and too much damp and cold at the roots. The remedies are obvious, but the warted appearance will hardly be removed this season by any treatment you may adopt. Increase the warmth of the border at once, but do not reduce the moisture in the air of the house too suddenly. Lessen it gradually.

PICTURES FROM CUTTINGS—STRAWBERRY FORCING (A Cottage).—You can grow your Pictrees from cuttings if you can get healthy cuttings from such plants, and they would bloom next year. We should be disposed to take the plants up and plant them carefully in fresh sandy loam, and see what that would do. If not experienced in striking cuttings, we fear you might lose plants and cuttings too. You will find in recent volumes, and even late Numbers, much on Strawberry forcing by Mr. Fish and others. It would hardly be worth while giving you an outline now, which might have to be repeated in July and August again. Success with early Strawberries in pots depends chiefly on having the pots crammed with roots before placing them in heat. That is not essential now. You can easily now pick out plants that are showing flower-buds. Raise these with balls that you can squeeze into pots, or plant at once in a slight hotbed. If you pot for the vinery, the plants would do better if the pots were plunged in a slight hotbed for a fortnight, with air on—say half an inch back and front. This would encourage the roots to grow, whilst the buds were kept cool, and when placed in the house the flowers would be stronger in consequence. They will do without that trouble, however, now, but better with it.

KEEPING BIRDS FROM CABBAGE SEEDLINGS, &c. (W. N. A.).—The soot and the sawdust, &c., sprinkled over the bed will only palliate the evil. Ruining white worsted strings along the bed, fastened to sticks a foot or more above it, and pieces of tin, glass, bits of looking-glass tied to the string—if the former, two together, so as to ring when moved by the wind—will do as well; but nothing answers so well as a piece of net, fastened at the edges of the bed, and supported on forked sticks in the middle a foot high, to prevent the birds reaching through. They get used to every scaring contrivance in time, and will even get their way below the net if not secured. Old fishing-net is so cheap, that after all, in the long run, it is best as respects simplicity and economy.

CULTURE OF RHODODENDRONS JAVANICUM AND JASMINIFLORUM, AND CYCLAMENS (A New Subscriber).—Keep the Rhododendrons in a cool greenhouse until they have finished making their wood; then place in a nice sunny spot out of doors, and give plenty of water during the summer and autumn, but not so much as to excite the flower-bud to grow prematurely. When the Cyclamens have done flowering, lessen water until the leaves decay, and then if the pots are set in a moist, shady place, they will need no watering until growth commences again.

DESTROYING WOODLICE (H. Lewis).—Lay a little dry hay down in their haunts. Provide yourself with a small fine-rosed watering-pot, filled with

water nearly boiling. Move the bay quickly with one hand, and scald the gentlemen with the other. Take some small pots, put a bit of boiled potato or raw carrot in the bottom, and place some dry hay or moss over it, half filling the pot. Go over all these the first thing in the morning, and tumble the myriads most likely inside into boiling water. Persevere and you will conquer. Let alone and they will conquer you.

FLOWER-GARDEN PLAN (A Young Gardener).—You have done your part to the very letter; showed the position of the dwelling-house, the greenhouse, the leading walk, the Americans and evergreens, with the independent beds on one side of it, and the principal flower garden on the other, the beds all numbered, and a list of plants showing what you intend for each bed. If you had put an arrow to show the south and north you would be entitled to a first-class certificate. Bed 6 is not planted, but you intend it, of course, to be the same as 2. No 1, the centre bed, is on a wrong principle, that was common in the last generation, when it was not uncommon to see a flower garden with the centre bed in scarlet or yellow. Put the plants intended for 1 into 8 and 4, then, with Commander-in-Chief in 11 and 14, your forces will be in position. Four or five plants of *Perilla* in the centre of 1, with three rows of *Flower of the Day*, or the like of it, round *Perilla*, and a row all round of *Lobelia speciosa*, would make the best centred bed in England for such a flower garden as yours. 9 and 3 should be exactly alike—say *Calceolaria*; and 5, 5 the opposite pair the same—say *Tropaeolum elegans*; or else cross-cornerways, 9 and 3 to match, and 3 and 5 the match pair. Either way will release the African Marigold for you. The way to do the African Marigold is to sow it on the 1st of May, to keep it out of sight, and transplant it twice—at the end of May, and again towards the end of June. When 18, the *Delphinium formosum* bed is over, early in August cut it down, and plant the African Marigold there, and some China Asters round it at the same time. You should have some hardy variegated low plant all round the big circle of *Roses*. Every large Rose-bed on grass, and away from other beds, should have a cheerful edging plant to it. If it is very large, a band of Variegated Mint would suit best. If it is 8 feet or 10 feet across, *Stachys lanata* is the best; and if only 6 feet across, *Cerastium* would suit better; but an edging there should be.

VARIOUS (A New Subscriber).—The *Dielytra* will do best planted out in summer, raised and potted in autumn, and kept in a cold pit in winter, when it will force into a flower whenever you give it a heat above 50°. The *Deutzia*, as soon as it has done flowering, should be well pruned to encourage making young wood; and if that is well ripened it will bloom all the length when subjected to a mild heat. It matters not whether you plant out and report, or report. We prefer the latter, and not having the pot too large for the plant. The *Hydrangea* treat in the same way; planted out, or in a pot, every well-ripened bud made on the shoots this season will produce a flower-head next year.

VARIOUS Inquirer.—Purple Orach is the same as the red. We will inquire about the nurseryman's address which you inquire for, perhaps he will advertise it next week. You have kept your Ten-week Stocks either too much in the dark, with too little air, or with too much heat; or you have ill-treated them in all these particulars. Sow the Asters in pans and avoid all the errors we have specified. You may sow Asters and *Phlox Drummondii* at once in beds under hand-lights; but the latter would be better in gentle heat. The names in parentheses after those of the Carnations, are the names of the florists who raised them. The plants can be obtained of any respectable florist. It is too late for planting the tubers of *Anemone* and *Ranunculus* to bloom at the usual time.

GOLD AND SILVER FISH.—"J. B." writes as follows:—"I have a tank brick and cement, in my garden holding upwards of one thousand gallons of water. There are very many gold and silver fish. Water from the Thames is supplied them almost daily. Within the last six weeks I have discovered many of them with a whitish slimy substance adhering to them, even covering the eyes. Most of such fish so affected, excepting the largest, died. Can you inform me of the cause and a remedy? There is gravel at the bottom, and Water Lilies growing." We shall be obliged by any of our readers sending us how to cure and prevent this parasitical affection.

PEAT CHARCOAL (R. B.).—There is a manufactory of it somewhere near London. Inquire of the London Manure Company. The Pomological Society is defunct.

LAURUSTINES KILLED BY THE WINTER (A. M. I.).—Leave them uncult down, as you say that there are some green shoots. If any vegetate this spring, then cut away all the dead portions. A curious exemplification of the Laurel being harder than the *Laurustinus* is now to be seen in the Westbourne Road, Bay-water. They were there planted alternately, and every one of the *Laurustinus* is killed, whilst every one of the Laurels is green and shooting vigorously. Your other question is answered in "Our Letter Box."

CINERARIA SEEDLINGS (—).—No. 2 may be a showy border flower, but we cannot be sure of that unless we knew the form and habit of the plant. The others are ordinary pips of no superiority.

INSECTS (A Subscriber).—The larva is that of the common Dragon Fly (*Libellula depressa*). The shells are *Philina aperta*, and the small white object is the very young state of an *Echinus*, probably of the genus *Fibularia*.—W.

NAMES OF PLANTS (F. Whittington).—*Fritillaria meleagris*, common or chequered Fritillary. (*S. Decon*).—No. 1, *Luciola sylvatica*; No. 2, *Cardamine pratensis*. (*A. F. H.*).—It is *Franciscea hydrangeaeformis*.

FLOWER SHOWS FOR 1861.

MAY 15th. CRYSTAL PALACE. (Plants, Cut Flowers, and Fruit). Sec., W. Houghton.

JUNE 5th and 6th. ROYAL HORTICULTURAL SOCIETY. (Plants and Fruit). *Garden Superintendent*, G. Eyles.

JUNE 19th and 20th. BRIGHTON AND SUSSEX FLORICULTURAL AND HORTICULTURAL SOCIETY. Sec., E. Carpenter.

JULY 6th. CRYSTAL PALACE. (Rose Show). Sec., W. Houghton.

JULY 10th. ROYAL HORTICULTURAL SOCIETY. (Rose Show). *Garden Superintendent*, G. Eyles.

SEPTEMBER 4th and 5th. CRYSTAL PALACE. (Dahlias, Cut Flowers of other descriptions, and Fruit). Sec., W. Houghton.

SEPTEMBER 11th. ROYAL HORTICULTURAL SOCIETY. (Dahlias and other Cut Flowers). *Garden Superintendent*, G. Eyles.

NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums). *Garden Superintendent*, G. Eyles.
NOVEMBER 12th and 13th. STOKE NEWINGTON CHRYSANTHEMUM SOCIETY. Sec., W. T. Howe.
NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show). Sec., W. Houghton.
N.B.—Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

MAY 21st, 22nd, and 23rd. CHESTERFIELD AND SCARSDALE. Hon. Sec., Mr. Thos. P. Wood, jun., Doythorpe House, near Chesterfield. Entries close May 1st.

MAY 22nd and 23rd. BEVERLEY. Hon. Sec., H. Adams. Entries close May 4th.

JUNE 4th, 5th, and 6th. BATH AND WEST OF ENGLAND. Sec., S. Pitman, Esq. Entries close May 4th.

JUNE 19th, 20th, and 21st. COALBROOKDALE. Secs., J. B. Chune, and Henry Boycroft, Coalbrookdale.

JUNE 25th. DREIFIELD. Sec., Mr. R. Davison. Entries close June 22nd.

JUNE 28th and 29th. TAUNTON. Sec., Mr. Charles Ballance. Entries close June 14th.

JULY 2nd and 3rd. BLACKPOOL. Sec., Mr. E. Fowler, jun.

AUGUST 26th, 27th, 28th, and 29th. CRYSTAL PALACE SUMMER SHOW. Sec., W. Houghton.

SEPTEMBER 3rd. POCKLINGTON (Yorkshire). Sec., Mr. Thomas Grant. Entries close August 26th.

DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. Sec., M. J. B. Lythall, 14, Temple Street. Entries close November 1st.

DECEMBER 11th, 12th, 13th, and 14th. CRYSTAL PALACE WINTER SHOW. Sec., W. Houghton.

N.B.—Secretaries will oblige us by sending early copies of their lists.

"FOR OUR KITCHENS WE KILL THE FOWL OF SEASON."

SHAKESPEARE.

WE have seldom had any communication that has given us more pleasure than that received from *One who has not lost sight of a Dorking fowl*. It is written by one who thoroughly understands the subject, and in that proper spirit of kindness which provokes the interchange of knowledge, and contributes to that sort of brotherhood in the pursuit, which has made many say they have formed valuable friendships while following their hobby.

Fowls are like human beings, and those that will attain to the largest size will be loose and long-membered. If all the food is expended in length, there will be nothing left for breadth; and though in a man there may be such growth of muscle as will prove that he is not outgrowing his strength, still there will be no deposit of fat. This is equally true of fowls, they will not put on fat till they have done growing. The birds known in England as "spring chickens" and in France as "*poulets à la reine*" are a peculiar breed, familiar only to those who have to do with them in the way of trade. It is next to impossible to describe them, as they have no marked characteristics. Some have four claws, some have five. They have no fixed colour; no peculiar comb. There is nothing to make them fancy birds; nothing to distinguish them from what would be indeed, named after appearances, Dunghills, or shabby little fowls. But if early maturity is to be taken into account, and if those that make food in the shortest time are to be the peers, we are not sure that these little Dunghills would not be premier fowls. These are the small breed; they begin to fatten six or seven weeks after they are hatched, and at twelve weeks they are complete in shape and form, and thoroughly fattened. At the time we now write such are making from 8s. to 10s. the couple. The stock birds are squat, square, and small. Age hardens them, but does not make them larger; and if, as it often happens, it is necessary to kill two or three of the old hens, and they are sent with young chickens—probably their own progeny—it is ridiculous to see the strong family likeness, and the small increase in size consequent on old age. It is valuable as affording proof of their purity as a breed.

People do not usually know, and they will hardly believe, the many thousands of pounds annually sent from London for this breed only. They are, however, only fit for those who look for flavour and quality, and with whom poultry is an adjunct to, but does not form, a dinner. For this cause they would not be saleable in any other market than London. In the country and in ordinary houses where "a couple of fowls" either form the dinner, or at any rate contribute the most important part of the first course, these chickens would be viewed with contempt, and then recourse must be had to the Dorking.

Dorkings are the birds that will sell in a country town on

account of their size, but they may be too fat; and then, like prize beef at Christmas, while they are admired as showing their capabilities in that way, and while wonder is expressed at the veins of fat intersecting the scanty lean, the fact rather renders them unsaleable than otherwise. It is impossible to fatten a Dorking chicken, if by that term we mean such a one as we have described at the beginning; but a good, large, fleshy, and moderately-fat bird, such as will sell in any market, must come from the Dorking.

It is easy after "Potage à la reine," "Saumon saucé Hollandaise," and so on, to look with loathing on a good, large wing; but if you have been throwing a fly over the Winchester or Andover white water all the day, and sharing the usual fate of the gentleman at table—have the leg at dinner—you will say the Dorking cannot be too large, and you will rejoice you are not in Sussex where the small and delicate chickens prevail.

A friend of ours says the Dorking is a curate's fowl, while the chicken should frequent fat rectories. If a referee be wanted to decide, we recommend the author of "Barchester Towers" to officiate.

The late Sidney Smith said "Barndoor fowls for Dissenters, but for the Thirty-nine-times-articled clerk of the Church of England the Pheasant, the Pheasant, and nothing but the Pheasant." We paraphrase the sentence, and we say, for the man who has an "embarras de plats," the chicken; but for the man who has been with the Cheshire, the Quorn, or Mr. Garth's, or who has flogged the river all day, we say the Dorking, and, in familiar parlance, we say, "The bigger the better."

We will return to this subject.

DORKING CHICKENS AT EXHIBITIONS.

THE opinions given by your correspondent, *One who has not lost sight of a Dorking fowl*, are quite at variance with practice. His words are—"It is very rare you see now-a-days a pen of prize Dorking chickens purchased at large Shows—viz., at Birmingham and the Crystal Palace, where there are great contests for the championship, which, when they arrive at adult age turn out anything like what the purchaser anticipated at the time of purchase."

It must be from a want of knowledge in the management, if you do not see the first-prize pen from either of the above Shows in the prize list wherever exhibited, if in health and not too fat.

Can your correspondent produce any one who has bought a first-prize pen of young Dorkings at either of the above Shows during these last five years, that has been so unfortunate as he would lead purchasers to believe?

I, for one, have at present three first-prize pens of chickens from the Palace, and very seldom show without gaining a prize.

Again, your correspondent says, "I can speak from my own experience. No Dorkings, I am sure, will ever get too fat by running in a farmyard and moderately fed." Now, on the contrary, I have had them get too fat running in the farmyard and not fed at all.

How different our experience! I have also had them become too fat for the judges when running in the centre of a very extensive park, by feeding night and morning only.

My Dorkings are all running in farmyards or woods, and are fed twice a-day, and are in good laying condition, and not put up to fat, yet they weigh from 9 lbs. to 13 lbs. and most of them have taken first or second prizes, either at the Crystal Palace or at the Birmingham Shows.

I should by all means advise intending exhibitors to purchase prize fowls at either of those Shows. If they can show them in good condition they will soon repay themselves. The Dorking is a fowl you can improve until three years old: therefore, if you see a pen of young Dorkings to please you, buy.—JOHN DOUGLAS.

PROFITABLE POULTRY KEEPING.

In your Number for April 2nd, at page 16, you favoured your readers with some interesting extracts from, and some just but friendly criticisms on, Mrs. Fergusson Blair's work, "The Henwife."

I have long kept hens for the purposes of profit only; and the point to which I would call the attention of your numerous readers is, the very small profit balance for the large number of "more than one thousand chickens annually hatched;" which

profit would be reduced to a certain loss, had the expenses of exhibiting, as you suggest, been placed on the debit side.

The county in which I resided (Shropshire), on my first essay in poultry-keeping, eggs were worth 1s. only per score in the laying season; and fat fowls were considered dear at 4s. the couple, the more usual prices being from 2s. 6d. to 3s. I have purchased fat young Ducks at 2s. 6d. the couple, when, as the local phrase hath it, the vendor had "overstood the market."

But to return to the more immediate subject. As before observed, I had kept hens with profit, even at the prices given above, when I removed into Hertfordshire, and there became acquainted with the system of poultry-keeping on a large scale; and in which the balance is on the right side of the account, to the tune of some—not tens, nor even hundreds, but—thousands of pounds in the aggregate.

This insight decided my course. I commenced at once, though on a very moderate scale; and I will give, with your permission, the results I attained.

My accounts begin but imperfectly; but when fairly at work, a daily journal was kept—not a chicken nor an egg being disposed of without an entry of the price obtained; and when for home consumption, entered at cost price. On the other hand, all grain, meal, bran, and the several et ceteras for poultry feeding, were duly placed on the debit side; and at the year's end, a moderate charge was made for management, rent, and interest, thus putting to the proof whether or not poultry-keeping is profitable.

And I can safely aver it is, and that to a great extent; the fact being established, profit is only a matter of degree. The want of capital alone prevents me turning my knowledge and practice to good account.

I well remember a writer, in one of the early volumes of THE COTTAGE GARDENER, stating that "a hen was as profitable as a sheep." I agree with this assertion. I can give data proving that the nett profit of poultry keeping is ——. Well, wait until the next Number, good reader; and then, with the permission of the worthy Editors, you shall know all.—LEIGHTON.

(To be continued.)

APPROACHING POULTRY SHOWS.

TATTON AND SOMERSET POULTRY SHOW.—This Society at their next show, offer thirteen pieces of plate and three silver medals, the former value £2 2s. each; and also money prizes between £50 and £60. The highest entry-fee is 1s. The Committee have a good subscription list, and everything promises well for a most successful exhibition. There are Sweepstakes (entries 7s. each) for Single Cocks of Spanish, Dorking, Cochins, China, Malay, Game, Hamburgs, Poland, and Game Bantam. Charles Ballance, Esq., is the Secretary; and we take this opportunity of saying that such secretaryship is always "honorary," except in the case of such extensive Exhibitions as Birmingham and the Crystal Palace.

DRIFIELD.—This is held in combination with a floral and horticultural exhibition; the prizes vary from 20s. to 5s., and the entry is only 1s. per pen. "Pigeons and Rabbits must be shown in the exhibitor's own cages or boxes."

HEN WITH STRADDLING GAIT.

THANKS for your advice upon the hen with straddling gait, but it came too late. She died yesterday. We saw she was worse, but did not expect her to die, as she pecked about as usual; but she had during the week made a noise like coughing, and the last day lost her voice entirely; she tried to cackle, but there was hardly the least sound: she breathed heavily, and seemed to be more stupid and giddy, if going backwards with head to the ground as if to avoid something before her eyes is a symptom of giddiness. Upon opening her there was fat similar to that of a Goose, and a little on the gizzard, but on every other part she was thin, the breastbone piercing through the skin. There was a number of yolks, and one in the egg-bag which she would have laid the next day; but the heart and lungs were not larger than a Bantam's, and the liver seemed large and dark; a great deal of inflammation was all round the covering of the bowels.

She never seemed to have any difficulty in laying, never remaining very long on the nest. She commenced her ailments two months back, with loss of power in the legs and great

nervous or convulsive action. She has had repeated doses of oil; but she never seemed right, and always had that straddling gait after she regained the power of her legs. With regard to feeding, I have followed closely the rules given in your valuable paper—feeding with ground oats, mid-day meals; barley and scraps for third meal. As to quantity, I must plead ignorance as to whether I over-do it. Will you say if it is over-feeding, as I have the sister Cochin, both being great pets? I should so regret losing the other, although she is nine months old and never yet laid an egg.

[We should say from the symptoms you have described, the hen died from over-feeding, but it, probably, took place long since. When there is as much fat as you describe, laying is always a matter of difficulty, and that would cause the awkward gait. We advise you to give the other three doses of a tablespoonful of castor oil at one day's interval, and to feed sparingly. The proper quantity may be easily known, if you feed only so long as the birds will run after a small piece of food. If it is given so long as they will pick, or if they have food by them, they are over-fed. *Feed less*, your fowls will be better, and will lay better.]

PIGEON JUDGING.

SOME time ago a suggestion appeared in *THE COTTAGE GARDENER*, relative to the points to form a basis for the judgment of Pigeons at the various exhibitions, and you were good enough to offer to place a space in your columns at the disposal of fanciers, for "comparing notes" on the subject. Encouraged and patronised as the Pigeon fancy has now become, the importance of some standard by which the value of the different varieties should be ascertained, and by which amateurs should be guided, is self-evident; for even at some of our largest exhibitions—such as Halifax, Birmingham, Crystal Palace, Preston, &c., it is not unfrequent to find it stated that in some classes the decisions at previous exhibitions were reversed. Certainly a margin must be left for individual fancy; and doubtless beyond some small peculiarity the awards are generally correct and impartial. Such is not the case, however, at some of our minor shows, and birds which have "figured conspicuously" at the largest exhibitions, are often unnoticed at the smaller shows.

The outlay incurred in obtaining the services of an able judge is seldom great, and in many cases merely travelling expenses are charged. But that such a person should be chosen from a distance, and unacquainted with the neighbourhood, is too apparent to require comment.

As it too frequently happens in notices of poultry and Pigeon exhibitions, the latter are merely referred to as "forming an interesting collection," with your permission, therefore, I will make a few remarks on the Sunderland Poultry and Pigeon Show, premising that my name did not appear in the catalogue. Chancing, however, to be in the neighbourhood, I looked in at the Exhibition, and made a few notes on the various classes, which may possibly be useful in future to exhibitors at a distance.

The entries for "Almond Tumblers," and "Tumblers, any other variety," were not large: the first prize in each being given to good birds; the second in the latter falling to a pair of "Long-faced" common Yellows, valued by the owner, and unclaimed, at 15s., the class containing two respective pens of Short-faced Mottles, Black and Yellow.

Carriers numbered seven entries, the first prize being awarded to a pair of fair Duns; a pen of Blacks, not on very good terms with each other, taking second; two pens being commended, one of which contained the best hen in the whole class, but associated with a slightly inferior cock.

Barbs had also seven entries, the first and second prizes being given to very inferior-crested Blacks. Two pairs of plain-headed birds, short in beak, and broad in head, with much superior eye, were passed over, one pen only being commended.

Powters only had four pens, and were not of especial merit; Blues taking the first honours, and Blacks second.

Trumpeters had four entries, the first prize being allotted to a pen of light Mottles, not much accustomed to each other's society, and anything but loveable; Whites, out of condition, gaining second.

The Fantail class was a good one, but the birds showed indifferently.

Jacobins mustered in great force, there being ten pens. The prizes were awarded to large coarse birds (Yellows), particularly

the second-prize pen. The former were, however, in good feather. A pen of small and fine Reds were commended.

In Nuns, both prizes were given to black-headed, good birds. The first prize in Turbита was gained by a pair of average Blues, a pair of Black-dappled being second.

Owls were an inferior class. A pen of crested Blues, without the slightest pretensions to points of head, beak, or eye, taking first; the second being awarded to a much better pen of Silvers. Two pens, White and Silver, respectively should have changed places with the successful birds, the first prize pair being unquestionably the worst in the class—in fact, not Owls at all. The remaining class, "Any other distinct breed," contained eleven entries; a pair of inferior White Barbs (crested), obtaining first, notwithstanding the Barb class, and Blue Magpies second; a pen of handsome Swallows, and a pen of fair Silver Runts, not being considered worthy of a commendation.—A FANCIER.

[We depart from our rule of refraining from criticising the decisions at shows, because the preceding emanates from a good authority, is written in good spirit, and because the committees of poultry shows are not so careful in selecting the judge of Pigeons as they are the judge of poultry. This is a great mistake, and unless a different course is adopted Pigeons had better be omitted from the competing classes.—EDS. J. H.]

BEE-HIVES AND THEIR APPURTENANCES.

(Continued from page 34.)

SWARMING-HIVES.—Being of opinion that, both as regards shape and material, there is no receptacle into which bees can be introduced, and more healthfully preserved with less care than

DOME-SHAPED STRAW HIVES, therefore these still retain a place in my apiary, with the undermentioned improvements, as *stocks to swarm*. At the same time it is well that every hive, before being used, should be so fitted as to act in emergency the part of a depriving-hive; as it sometimes happens that the hive so destined will fairly exhaust one's patience, although blocked out at the entrance, determinedly clinging to the old abode; while it may chance at the very time, another we had hoped great things from as a depriver will show, despite every effort to prevent, as strong a predilection to be off. To save time, it therefore becomes good policy to let each follow the bent of its inclination.

Success in bee-keeping depends, in a measure, upon being guided somewhat by the habits and instincts of the insects. I never, therefore, liked the principle of returning swarms, particularly seconds; far better to hive them at once as they come off, strengthening the parent hives at the end of the season with the inmates of the condemned stocks, right and left, as recommended by Gelieu. The returning but leads to a fresh exodus on the first opportunity, causing endless trouble to the apiarian, and keeps the stock in a continual hubbub.

I place my seconds, one in an under-sized straw hive, if early and strong—if later, two or three or even more together in a larger hive; these, stimulated with a little spring feeding, and possessing a young queen, make capital swarmers.

The district and bulk of swarms must somewhat regulate the size of hive. 14 inches inside are the width of mine—a dome-shaped, about 9 inches in depth to the eaves. The standard I have adopted is about 1300 cubic inches, or say, in other words, such a size as a box 12 inches square by 9 inches deep. I have wrought successfully this size with end openings, and have never yet found brood in a super—of course I mean single prime swarms of the season, destined to swarm the succeeding year.

It is a poor season indeed that a fair swarm does not yield something, and generally keep itself through till the next. Should need be, however, a little feeding is supplied in the beginning of March.

A simple mode by which the size of round-topped and other odd-shaped hives may at once be contrasted with the standard, is to fill a box of the desired dimensions with clean grain, and empty it into the other.

The bands of common straw hives are generally about three-quarters of an inch wide; they can be very beneficially increased to 1 inch or 1½ inch. I have often heard cottagers remark, that somehow their thick skeps were always lucky. They should all be wrought with cane, and attached at bottom with the same material to a good hard wood hoop, through holes bored with a hot iron to prevent splitting: this adds greatly to their durability.

Boys' playing-hoops answer the purpose very well—those of ash—cost a copper or two, at any toy-warehouse, are to be had of all sizes, and ready for use. A nicer mode, although more expensive, is to cut, with a saw out of three-eighth-inch dressed board, two flat circular rings of a breadth corresponding with the thickness of the straw, lay one above the other with the grain of the wood reversed, carefully glue and sprig together, and attach to the under band of hive with screws; as much of the lower ring to be cut out in front as is required for an entrance, the upper with the straw affording shelter to the bees about it. My straw hives have a small window behind placed in an aperture cut $4\frac{1}{2}$ inches by $3\frac{1}{2}$ inches—of course, the bands taken out must be of the full thickness; a bit of dressed board of similar thickness as the straw is made to fit tightly into the space; a piece $3\frac{1}{2}$ inches by $2\frac{1}{2}$ inches cut out, leaving a frame of half an inch all round; a rabbit of a quarter of an inch is sunk to receive the pane, which can be retained in its place with putty or four little quarter-inch slips of wood sprigged. An odd end of a slide (bar-and-slide hive-tops), one edge run off and sprigged on with the rabbit side inwards, is available to work a small shutter of quarter-inch wood, $4\frac{1}{2}$ inches by $3\frac{1}{2}$ inches, with a fine rabbit cut in it to match the other. The entrance is 5 inches by three-eighths of an inch cut through the hoop, contractable at pleasure, as will be afterwards explained under "entrances."

FLAT-TOPPED STRAW HIVES are 14 inches wide by 9 inches deep, wrought on hoop-window and entrance as above, are fitted as deprivers by cutting out each top-end band of straw, the space filled up by dividing a bar (bar-and-slide hive) into two, and securing it to the straw back and front; into the grooves in the bar, a half-inch or five-eighth-inch slide is wrought. The bees by this means are admitted by both ends into the octagon super, if such be used; if bell-glasses, one can be placed over each opening. Any inequality in the straw of the top of the hive where the super rests can be made up by tacking a little slip of wood round the box. I omitted to state above that a similar mode for an entrance to the super can be resorted to in dome-shaped hives, with this difference—that the super rests on a board screwed on the top of the hive, the bees being admitted into it by the ends as before; the communication between the ends of the hive and the top-board effected by two thin pieces of wood secured, half-an-inch apart, with end pieces, and passing through slots cut to receive them in the top-board. These uprights are kept from slipping into the hive, or too far through the board, by little pieces nailed round acting as flanges; the top-board and these end pieces only remain on the hive when required for supering.—**A RENFREWSHIRE BEE-KEEPER.**

(To be continued.)

EARLY HARVESTING OF POLLEN.

I HAVE observed that in some of the communications lately inserted that your apianian correspondents in England appear surprised at the statements made by your Renfrewshire correspondent, of his bees having been seen carrying pollen on the 27th of January last.

As I feel a great interest in all the movements of these industrious insects, I have frequently noted down in my pocket-book remarkable observations of their swarming, and early or late industry, &c.; and upon reading those articles upon the apiary above referred to, I was induced to look over my pocket-book, where I find it noted, January 28th, 1861, "Bees seen working upon snowdrops in the open air; and again February 1st, working and carrying pollen upon crocuses, snowdrops, and *Jasminum nudiflorum* in front of my house, which is brick, and facing the south." On looking back at former dates I see they were first seen on flowers on February 10th, 1856; and on the previous year (1855), which had a severe winter and very late spring, they were first seen on flowers April 17th—an amazing contrast, certainly to the present season. I see I have it also inserted as being unusually late. Bees working and carrying pollen "freely" on November 14th, 1859.

These extracts may prove interesting to some of the bee-keepers in the south "if you consider them worthy of insertion." I may also remark that this place is in the east corner of Morayshire, and is upwards of 200 miles north of Renfrew. The remarkably warm and soft south-west wind, which we had here of above a fortnight's duration towards the latter end of last January, and beginning of February, gave a stimulus to vegetation, which a week's frost in February failed to check; and

everything was nearly as forward on the first week in March as it was in 1859, when everything was so early, and which was preceded by so mild a winter. The lowest night temperature on the 27th and 28th of January last was 47° and 48° respectively.—**JOHN WEBSTER, Gordon Castle.**

P.S.—I had almost omitted to remark that there are but few deaths in our apiaries in this quarter, and although weak, the bees are carrying pollen freely at this date (April 5th).

DURATION OF QUEEN BEE'S LIFE.

INTRODUCING A LIGURIAN QUEEN INTO A HIVE OF COMMON BEES.

ON looking over what I am quoted as having written in reply to your correspondent "H." at page 375 of your last volume, I find an error, whether of my own or your compositor I cannot say; but if mine I must apologise to "H." for having written so carelessly. The error (obvious enough to every bee-master), is contained in the following words:—"The queen in our correspondent's hive (which hive is a swarm of 1859), will last two years longer in a vigorous condition." If, instead of "will," "H." will read "may," the error will be corrected; but it must be added that if "H." does not know the age of the queen, she may also be drawing very near the close of her natural life. I certainly understood that your correspondent's hive was not itself a swarm of 1859, but that it had given out a swarm in that year, in which case the full term of the queen's life would not expire till 1863—i. e., assuming that queens live four years.

Permit me to suggest a method of introducing Ligurian queens into established stocks, which I intend to adopt myself this season. I have three queens, known to be old, at the head of very rapidly increasing stocks; these I intend to compel to swarm artificially as early as possible, if I can procure the Ligurians to take their place. Each artificial swarm will be made to take the place of the old hive, which will thus be denuded of all its full-grown bees. The next day, or, better still, in the quiet of the same evening, I shall introduce the Ligurians. The young bees, I take it, will offer little or no opposition. To succeed the Ligurians must, of course, be in full laying trim, and impregnated by the males of their own species beforehand. In this case they would very likely swarm themselves in June; but their offspring (queens), would very likely be hybrids, as there would be, most probably, a good deal of drone-brood in their usurped dominions. This, however, might be carefully cut away at the time the swarm was artificially made.—**B. & W.**

WHAT ARE THE TRUE DIMENSIONS FOR COMB-BAR HIVES AND BOXES?

SINCE replying to the inquiry of a "NORTH-LANCASHIRE BEE-KEEPER" on this subject, I have been indebted to the kindness of a friend for the possession of a copy of the Rev. L. L. Langstroth's work on "The Hive and Honey-Bee." As it is to this gentleman that American bee-keepers owe the introduction of bar-and-frame hives, in the use of which he has had great practical experience, due weight should certainly be given to his opinion. On examination I find that he names $11\frac{1}{2}$ inches as the proper width to accommodate ten bars. Although this is much closer than I should have ventured upon without such high authority, I have given the subject my most earnest attention; and having for various reasons arrived at the conclusion that Mr. Langstroth is correct, I am now altering all my stock-boxes of 13 inches square from eight to nine bars, increasing at the same time their depth from 7 inches to 8 inches and allowing sufficient space above the bars to give free passage to the bees.

I do not urge a "NORTH-LANCASHIRE BEE-KEEPER" to follow my example, because it is as yet quite an experiment, and may turn out an unsuccessful one, although I cannot confess to any misgivings on the subject. In due time I shall have pleasure in communicating the result to the readers of *THE JOURNAL OF HORTICULTURE*.—**A DEVONSHIRE BEE-KEEPER.**

BEE ROBBERS—TREATMENT.—When robbing bees attack a weak colony having a fertile queen, it is advisable to remove it from its stand to a dark chamber or cellar. Set an empty hive in its place, strew therein a handful or two of the stems and leaves of wormwood, and rub the front of the hive and the bottom

board therewith. The assailants will soon forsake the spot, and the colony may be replaced on its stand on the evening of the following day.—(*American Bee Journal*.)

CANARIES' FEET DISEASED.

In answer to "R. S. V.," I beg to say that one of my best birds was afflicted very much in the same way. The leg from the toes to the first joint up began to swell on one foot. I took the bird out and carefully examined the foot, but could find no trace of hair or anything round it, although I used a powerful magnifying glass. I bathed it in warm water, and likewise gave it a drop or two of sweet spirits of nitre in its water, and plenty of groats to eat. In two days after the upper part turned black and all the scales fell off. I again took the magnifying glass, but could find nothing to indicate the cause. With frequent bathing in warm water the disease went off in about a fortnight.

I think if more frequent communications on these subjects could be obtained, a vast amount of useful information would be brought forth in your paper, both interesting and useful to bird breeders.—WM. YOUNG.

[Our columns are open to all correspondence upon such subjects.—EDS. J. H.]

CATCHING TOMTITS.

A "RENFREWSHIRE BEE-KEEPER" writes that his bees were annoyed by the large black-headed Tomtit (*Parns magnus*), during the late winter. I have always found these birds more destructive in November, December, January, and February only, in seasons moderately cold; as, during extremely severe weather, the bird cannot entice bees to the entrance, which ought, in fact, always to be stopped with wood or tin in such weather.

The Tomtit prefers the straw hive much more than the wooden box for his predatory habits; but I have recorded in Vol. VII. or VIII. of THE COTTAGE GARDENER my mode of destroying what they call in Hampshire the great "bee killer." Take one of the inexpensive common mouse-traps, price 4d., and bait it with suet or a bit of bacon fat, and place it on the top of a hive or box. My straw hives are covered with earthen pans, and these coverings do to place the trap on. In the course of a month sixteen of these impudent birds were caught in this spring-trap, and not one Robin. I quite agree with your correspondent that the placing of poison is a cruel plan, as the innocent too often suffer for the guilty. The great Tomtit is as fond of suet as many aldermen are said to be of turtle; and the bird is fond of looking into little holes and corners, pulling out straws, &c., for the insects concealed there.

During the summer when grubs and caterpillars are plentiful, I have never found these birds at all troublesome except in attacking my green peas.—H. W. NEWMAN, *Cheltenham*.

SCARCITY OF STARLINGS.—I should be glad to know from your correspondents in various parts of the country whether they have noticed this spring an extraordinary scarcity of Starlings. In this neighbourhood I have not seen one, although the church and rectory for many years have been the favourite resort of hundreds of these birds. Are we to conclude that they were all killed by the severity of the winter, or that from lack of food, they migrated to less inclement latitudes? If we take the former alternative, they must be a more tender bird than is generally supposed; if the latter, how is it that not a single pair should have returned to their old haunts?—E. M., *Gaithersburg, Cheshire*.

VARIETIES.

TO CLEAN TAINTED BARRELS.—The best method for cleaning tainted barrels is to put one peck of charcoal and one teacup of potash into each barrel, fill them up with boiling water, cover tight, and let them stand until cold.

HOW TO TRANSFER PATTERNS.—Transfer paper is certainly the most easy and convenient method; if it cannot be purchased, it can always be made in a few minutes in the following manner:—Take a sheet of thin writing paper, and with a piece of wadding or flannel rub it all over with a little sweet oil, carefully removing any superfluity on the surface of the paper; then rub on to this oiled paper a little colour, either light or dark, according to the

colour of the material on which the work is to be executed—if a dark cloth, for instance, a little chrome yellow is the best; if a light drab or any pale colour, a little common blue makes the lines perfectly visible. This colour must also be well rubbed into the paper, so that none shall be left on the surface. When the paper is thus prepared, place it on the material and lay over it the pattern to be transferred, and with an ivory knitting-needle or a stiletto, trace the outline of the pattern, which will be found to be transferred to the material with perfect distinctness, if properly managed.—(*Peterson's Magazine*.)

SALLY LUNN.—I am tempted to send my recipe for this most delicious tea bread, which, once eaten at your table, will cause your friends to rejoice when asked to come again. Take a stone pot, pour in one pint bowl of sweet milk, half a teacup of bakers' or other yeast, one-quarter of a pound of melted butter, a little salt, and three beaten eggs. Mix in about three pint howls of flour; let it stand several hours, or until quite light; then put it into Turk-heads or other tin pans, in which Sally should again rise up before being shoved into the oven, to be "brought out" and presented to your friends as the beauty and belle of the evening.—(*American Country Gentleman*.)

HOW THE JAPANESE REVIVE FLOWERS.—Another little practice I would mention here for the benefit of those who love to decorate their rooms with flowers. After a bouquet is drooping beyond all remedies of fresh water, the Japanese can bring it back to all its first glory by a very simple and seemingly most destructive operation. I had received some days ago, a delightful bunch of flowers from a Japanese acquaintance; they continued to live in all their beauty for nearly two weeks when at last they faded. Just as I was about to have them thrown away, the same gentleman (Japanese gentleman) came to see me. I showed him the faded flowers, and told him that, though lasting a long time, they had now become useless. "Oh, no," said he, "only put the stem ends into the fire, and they will be as good as before." I was incredulous. So he took them himself and held the ends of the stems into the fire until they were completely charred. This was in the morning; at evening they were again looking fresh and vigorous, and have continued so for another week. What may be the true agent in this reviving process I am unable to determine fully: whether it be the heat driving once more through every leaflet and vein, or whether it be the bountiful supply of carbon furnished by the charring. I am inclined, however, to the latter cause, as the full effect was not produced until some eight hours afterwards; and as it seems that, if the heat was the principal agent, it must have been sooner followed by visible changes.—(*New York Herald*.)

OUR LETTER BOX.

HENS DYING WHILE LAYING (*K. M. L.*).—The cause is told in one of your own sentences—"when pended they are very fat." This and their appearing "dull and heavy," demonstrates that they are fed too well. Give them each a table-spoonful of castor oil, no barley, and no "bits from the kitchen." Give them a little soft food at night, and nothing more all the summer, as they have "a good run, and access to water and grass."

DORKING WITH FESTERED FOOT (*A Constant Subscriber*).—The festered foot is probably the remains of the frostbites. Very many birds lost part of their toes down to the first joint. Remove the cockerel from the yard if it has a hard surface, and place him on grass. After your feeding, barley is never good food if fowls are confined to it. It is worse than usual this year, owing to the bad quality. Get some oats, and have them ground very fine without taking away any part. Let this be slaked with water, and feed with it. Your fowl's will then get well. You need not be uneasy about the diarrhoea.

LOP-EARED RABBITS (*L. E. R.*).—Refer to the lists of prizetakers, and write to them or what you need. You will see a drawing of a first-class Lop, and all the points desired, detailed in our No. 648. First series.

MANAGEMENT OF GOATS (*M. Fitzgerald*).—If written by the party you mention, the information is not the result of his own experience. We shall be very much obliged by any one who has successfully kept Goats for the sake of their milk, favouring us with particulars of their management the kind of Goat they kept, food, &c.

LONDON MARKETS.—APRIL 15.

POULTRY.

There is still a real dearth of poultry. It is likely to continue for some time, as the high prices will cause senders to prefer a present large price to a larger in perspective.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 53.8° and 36.8° respectively. The greatest heat, 81°, occurred on the 28th, in 1849; and the lowest cold, 22°, on the 22nd in 1859. During the period 133 days were fine, and on 105 rain fell.

THE EDUCATION OF YOUNG GARDENERS.

THE amount of education necessary for a young gardener previous to his undertaking a responsible situation, has been for some time occupying the attention of one or two of your contemporaries. But the amount of good that is likely to accrue from their various opinions on the above subject I am not at present in a position to surmise; but it is very likely to end as it began—namely, in nothing—as I am afraid some of them are recommending an education which they themselves are not possessed of, and, moreover, far beyond the reach of the majority of young gardeners—and if they were possessed of it they would seldom, if ever, require it for any practical purpose.

The following are some of the branches of education which I think we young gardeners ought to be possessed of—viz., land surveying,

wood and timber measuring, mason's and bricklayer's work, carpenter's and joiner's work, plasterer's work, glazier's work, book-keeping, and practical geometry. A gardener who superintends a place of any pretensions requires one or other of the above almost daily: and they are no more than what any young gardener may teach himself, and practise during the long winter evenings, which will be turning leisure moments to a profitable account, and will be of infinite value to him, if he is spared to undertake a responsible situation, which he would be very unsuitable for if he were not possessed of such knowledge. But a gardener may be well initiated in history, be a good politician, can talk French and Latin, be a good mathematician, geometrician, geographer, grammarian, botanist, &c., yet be possessed of a very indifferent knowledge of his profession. It is a true remark that Mr. Beaton recently made in THE COTTAGE GARDENER—namely, "All the learning, and all the education in the world, will not avail a man who wants a practical knowledge of what he takes in hand to do: and as there is no way by which a man's practice can be tested before he sets to work, all the tests of efficiency by education may turn out in empty bushels."

A gardener possessed of a first-class education would be but a poor compensation to an employer if he were compelled to use and treat his friends to inferior or worthless fruits, or when visiting the garden to be continually meeting with sickly or unhealthy plants and other unsightly objects, which can only be attributed to the want of practical experience and good judgment on the part of the gardener: therefore, I insist that a young gardener's first ambition ought to be to gain a good practical

knowledge of his profession, without which it would be utterly impossible to give an employer any degree of satisfaction. On the contrary, it would cause an employer to remonstrate with him on the small success attending his labour, which too often ends in a separation—a procedure which is not very satisfactory to an employer any more than it is to the employed.

Having thus far glanced at some of the most essential branches of education necessary for a young gardener who is about to undertake a responsible situation, I will, with your permission, make a few remarks on the class of establishments out of which a good gardener is likely to be obtained.

A good many noblemen and gentlemen are of opinion, when in want of a gardener, that the best place to apply for one is at a first-class establishment. For so doing they are in a great measure justified: because, if a young gardener has held a responsible position in one of these establishments for two or three years, and during that time has given his superintendent every satisfaction, he also is a likely person to give satisfaction to an employer, as the majority of head-gardeners in first-class establishments are men whose practical abilities are in unison with the places which they hold: consequently the instructions which they would impart to such a young man relating to his various duties, would be based on such sound principles and long experience that the young gardener would become in a great measure a stranger to failures.

Nevertheless, there are others that are rather prejudiced against taking a gardener out of a first-class establishment; and they are not void of a reason for being so, as they are aware that many of the superintendents of the above places require premiums from young professionals for merely allowing them to work on the establishment, giving them a promise to assist them into a more remunerative situation. A young man's professional abilities are sometimes a secondary consideration with these wholesale dealers in gardeners, and the more demand they have for men to fill responsible situations, the faster can they pocket the premiums.

Employers are also aware that the greater part of the majority of these young men's time is employed in one particular department, consequently they must be very often in ignorance of what is going on in many of the other departments: therefore, unless these young men are pretty familiar with the various branches of their profession previously to their entering into one of the above establishments at all, their chances are few to become familiar with them after. Nevertheless, out of one of the above establishments a gentleman may obtain a first-class gardener, as a good many of these young men are well initiated into their profession previous to their entering into the far-famed place at all—their object in going there being merely to facilitate their getting a better situation.

I must also beg leave to make a few remarks on the gardeners employed in second-class places. A great many of these men are as good practical gardeners as their more fortunate brethren. It is even necessary that

they should be the better gardeners of the two, as there may be some of their employers who are very partial to their garden, yet from circumstances are unable to expend the amount they could wish either towards improvements or keeping them in proper order: therefore, it is necessary that their gardeners should be of first-class abilities, that they know the value of labour, time, and money, that they know what improvements really are, and the best and cheapest modes of accomplishing them. A gardener in a first-class place, when effecting a supposed improvement, if it fall short of the desired effect may pull it all to pieces, it being no matter what expense it may have occasioned, and he may try again on a different plan.

How many gardeners are there in second-class places that could practise the above and give their employers satisfaction? Such a gardener, also, to some extent finds it necessary to study the various tastes of the men whom he may have under his charge. As he finds that some are more partial to, and can accomplish some kinds of work with greater alacrity than others, therefore, he tries, as far as practicable, to let each man have his favourite work, for by so doing he can have it better done and more of it, without showing in his manner the least appearance of tyranny—and when he has to correct a man, it is with as much deference as the circumstances of the case will admit—his words are few, but they are to the purpose. In short, he avoids everything that would tend unnecessarily to wound the feelings of the anxious-to-do-well workman.

Such men are not only respected by the working men, but they are as highly respected by their employer, who in time looks upon his gardener almost as one of his own family.

I am sorry there are exceptions to the preceding remark. The gardener is not always appreciated according to his value, or as a trustworthy anxious servant ought to be; but when he has spent the noontide of his days in a master's service, that master invents some lame excuse to part with him, in order to avoid providing him with the means to assist him to a crust of bread, or to smooth the pillow of an old but honest servant. I hope such employers are few, and I hope there are fewer old gardeners depending upon the charity of such employers.—AN UNDER-GARDENER, *Sudbury Hall*.

A TREAT FOR AURICULA LOVERS.

"STILL harping on my daughter?" "E'en so may friend Othello say. And why not? Is she not charming, "all my fancy painted her—lovely and divine?" I advised, some time ago, any one who wanted a treat in flowers to run down and see the Slough Auriculas; and not being willing to advise what I do not practise, I took a recent opportunity of being in London to make the trip myself; and having undergone the operation, I can most conscientiously recommend any whose eye is at all educated for such matters to follow my example. It may be this will fall under the notice of some reader who heaves a sigh at the recollection of what he formerly did in that line and now has abandoned. I say to you, my friend, Go down. The virus will probably take, and you will again find yourself numbered amongst the honourable fraternity. Or some one who, rather sick of nothing but bedding out, desires to cultivate some florists' flower. To you I would say, None so worthy of your care as this. "Pooh, pooh!" I hear some say, "that's all very fine—that's what every one says." Then Lady Jemima calls all her acquaintances to admire the beauty of Fidèle—a nasty, wheezy, fat porpoise of a spaniel. While Tom Rattler bids you observe the beauty of his superlatively ugly Skye terrier, Dr. Dryasdust bids you run off to Kent and admire the sublime grandeur of Richborough Castle—and you only see a dry, crumbling wall. Mr. Sirlolm bids you mark the beauties of that beifer he is about to slaughter, discourses severally of its points, and tells you how perfect she is—you see only an obese round-barrelled-shaped brute, the best part of which will go to the cook's tub and the tallowchandler's vat.

Ah, well! our hobbies are, I suppose, all equally absurd to those not interested in them, and equally valuable to ourselves; only let us not ride them to death, which, by-the-by, some may say I am now doing. To vindicate myself, I will just say what a florist will see if he follows my advice:—A large frame, containing a first-rate collection of Auriculas in full bloom, consisting of all classes and of a large number of varieties, both new and old, in the fullest vigour, perfect health, and full bloom. Of course, to many eyes they will seem too stiff and regular to have any real beauty in them—very curious, doubtless, but by no means handsome. Now I say they are unique—that there is nothing in the whole range of floriculture like them. Here is one—a truss of brilliant blue or light purple. Here is another of deep crimson. Here another of maroon. Here one, the edge of which is a brilliant green, with a deep rim of intense black inside a pure white circle, and a yellow eye—a quadricolour, in fact. Here, again, one with a soft grey edge and a splendid violet band, and yet another white-bordered. Then, again, look at the foliage. While some are of a brilliant green, here is another with leaves as white as if the good housewife had dredged them all over with flour; while another has a beautiful thin line of white running round a green leaf, like the silver braiding on a uniform, another has a white line up the middle of the leaf: and therefore I say, both in foliage and bloom they are quite unique.

There is, too, here a fair field open for the hybridiser; for the accessions of late years have just shown that, while here and there a few flowers of surpassing excellence have been raised, they have been so few as to show that more care must be exercised: and let it be well known that, amongst florists, he will be considered A 1 who raises a first-rate Auricula.

Amongst the new kinds which I saw in bloom were—Smith's Richard Cobden and Lord John Russell, Spaldry's Metropolitan, Smith's Lady Sale, Charles' Mary, Headley's George Lightbody, Richmond's North Star and Volunteer, Turner's Rev. George Jeans, and Chapman's Maria. While amongst older varieties were remarked as very fine—Taylor's Glory, Drew's Lady Jane Grey, Spaldry's Blackbird, Netherwood's Othello, Maclean's Unique, Smith's Waterloo, Waterhouse's Conqueror of Europe, and Popplewell's Conqueror.

Nor were Auriculas the only things worth seeing. Cinerarias also were very fine. A good race of self-coloured varieties has been raised. Brilliant has been exceeded by Duke of Cambridge and Adam Bede; while a seedling of last year, though somewhat coarse, is likely to prove valuable as a flower of Brilliant colour—the Rev. Reynolds' Holo. Miss Eyles is a most free-flowering variety—white, with a brilliant border of earmine. These two, with Maid of Astolat, are decided acquisitions, brilliancy of colour being joined with excellency of habit.—D., *Deal*.

CROSS-BREEDING FLORISTS' FLOWERS—A RIBBON-BORDER FOR THE MANY.

If I were disposed to write on bedding plants as against florists' flowers, and if my race and kindred had been of the Mac Ian Mhor kith and clan, I could not have coveted a more competent rival in the lists than "D," the writer on Florists' Flowers in THE JOURNAL OF HORTICULTURE. To aspire to break a lance with a better-mounted knight, or with a cavalier of less fresh fame than he who lusts for fortune in a fray, is neither prudent nor peculiar in our day: therefore, if I came out of the fray second best, all they could say about it could only amount to a want of prudence or a desire for notoriety—two things bad enough in themselves, which I could afford to turn to good account in an encounter between beds and circles, between substance, shape, and colour, or between a "D." on one leg, and a "D." with a "B." to banter with. But just now we are too busy to entertain such notions; and all I want to say is this, that if the florists do really hybridise their breeders as "D." says in last week's impression, I can spare them the one-half and the most difficult part of their labour entirely by one stroke of this pen. With two exceptions—the Fuchsia and Pelargonium, there is not a single or double florists' flower on record which needs hybridising at all, or which will produce a better seedling from all the knowledge of the cross-breeder. And even more than that—hybridising can only spoil some few kinds of florists' flowers from the moment the kind is improved as to be worthy the attention of a florist. Not a word of this is on hearsay, I have proved every word of what I assert.

But this law in crossing flowers goes very far beyond the province of the florist, and of the flower-beds. One party who took up one side of Mr. Darwin's ideas on the origin of species, are quite as much at fault as he who believes he has effected a cross because he went through the process of introducing strange pollen to the pistils of all his seedlings for a quarter of a century. I am not quite certain that the Hollyhock might not be relied upon for giving one-half of the merit of seedlings to the effect of crossing; and I know that to balance that, one-half of the merit of seedling Fuchsias is not due to cross-fertilisation. I was the first man, and, I believe, the only individual who ever crossed all the wild Fuchsias, &c. Thirty years since I proved the origin of several Mexican species of Fuchsias, and recorded the facts; and although I have not crossed a Fuchsia for the last twenty-five years, I am perfectly cognisant of how the law of crossing affects them.

One might think—and a florist who only crossed florists' flowers would never find out the difference—that a law would apply equally to all families of plants. That is far from being the case, however. But, to understand that, know that under cultivation every plant that is crossed is at the same moment under the influence of two sets of laws, and may be under many more.

The first law is, that the organs of reproduction be ripe or ready for the process of crossing. The second law is, the degree in which both the parents are different from their natural law of growth in a wild state. There is no plant in cultivation in the exact state it enjoys in its wild nature. It is either so much better off or so much the worse; and the degree of so much better or so much worse, is the second law I mean.

Then follow the laws of how these degrees are brought about; and here is where nothing that we yet know of can guide a man save actual experience, for the law acts very differently on two genera which are exactly under the same process of culture; so that your experience on one of them is not, or at least may not, be of the smallest use to you in your dealings with the second.

All our real English florists' flowers are improved only by an improved system of culture. The Dahlia, the Pelargonium, and the Pansy are far more improved by the highest cultivation than the Clove tribe, as Pinks, Picotees, and Carnations. Their degrees are different, and the foreign pollen is not of the slightest benefit or the smallest injury to any one of them.

On the other hand, your very highest degree of superior cultivation goes entirely for nothing in crossing Roses, or in raising seedlings of them without crossing: therefore, they must be under a third law, and I know at least seven more laws, making ten distinct laws, which affect crossed flowers in one way or another. But if I induce a new flower to cross, I cannot tell, and no one can tell me, which of these ten laws governs it most, or if even one of them affects it at all.

When a man tells me he has taken to crossing his flowers from reading the ways of cross-breeding in THE JOURNAL OF HORTICULTURE, and he finds now he can do anything, I compliment him of course; but I am at the same time well aware that our Journal is not yet of sufficient age to have taught him any such thing. At the end of a dozen years of extensive crossing, a man at least can only be sucking his thumb on the subject. I, who have sucked both thumbs on it since 1818, am obliged to own how very little I really do know of the laws by which vegetables are governed for good or ill in cross-breeding. But I know quite well that florists will raise as many good seedlings without foreign pollen as with it, with the said limitations. Let them only try and tell the result. Then, but not till then, shall I be able to show them just as clearly and with much less writing, where they and their humble servant mistake means for ends and ends for means. We are both of us so far in the wrong.

But, bless me, what I was going to say was, that I saw more spring flowers this spring than I have seen for the last ten years put together, and that among them was *Ranunculus amplexicaulis*, of which I had known a gay bed in March, 1823, 1824, and 1825 at Altyre, near Forres. It came in before the white *Arabis præcox*, *alias* alpina, and lasted longer and was as white; but the bed was not just so telling as the one of *Arabis*, because there was more room between the flowers to see the green leaves.

In those bygone years we began the year with Snowdrops, Crocuses, *Ranunculus amplexicaulis*, and *Arabis præcox*, as "D." says the florists now do with Pansies and Auriculas; but ours at that time ended with the Naked and Painted Ladies—the autumnal Crocuses.

Pansies were not thought of then, and double Dahlias were not so common nor one-half so gay as the single ones. Auriculas were then at their prime, and Polyanthus—I mean both as florists' flowers—were just beginning to decline in favour. Pinks and Carnations were as hotly cultivated as at this day; and we had a yearly supply of Picotee seeds from Naples, and beds and borders of seedlings of all the florists' flowers of the day that would surprise some of the great growers of the present day. The father of the present Duchess of Sutherland, before he was married, was a welcome visitor at Altyre; for he, too, was fond of florists' flowers, and first taught the baronet who now enjoys the place to know and like them for their own sake.

But in my capacity of a paid advocate on the other side, I have been often requested to propose a kind of John-Anderson-my-jo-John sort of ribbon-border for the million—one that a duchess might go to Court in; and, at the same time, one that the old woman who opens the lodge gate might set up as her own ensign of decorative principles, without seeming to appear to her betters to be aiming at the frivolities of fashion. I have stedfastly held to the opinion, however, that, in order to improve the taste of our people, the best plan to pursue is to give unbounded scope to all degrees of taste among them, to induce them to open their minds confidentially as to their own ideas of any particular taste in planting, and then, without making a parade of their lack of knowledge of the principle on which they acted, to show them how to square it with the principles of the present fashion. That, I am convinced, is the true way to act when you have to do with all degrees of ideas of taste. Make no efforts to change a taste or to make a covert in taste.

Nevertheless, I cannot foresee any great harm that could come of a John-Anderson-my-jo-John ribbon-border, only that I would not be supposed to insist on it. Here it is, therefore, and I do assure you I like it myself.

The length is to be the whole run of a border, either straight on or bended gracefully into curves; all you will have to do will be to plant every part of each row at the same distance from the edge of the border. This season the first row must be of *Cerastium tomentosum*, planted in a single row, 4 inches from the side, and 4 inches plant from plant—the smaller the bits the better, and allow 1 more inches on the off side to spread, or 8 inches when the plants are at full run. From the middle to the end of April is the best time to do this; and if there is a close row of Crocus leaves in your way, plant two rows of *Cerastium* 6 inches plant from plant, one row in front, and one immediately behind the Crocuses. When there is a chance, put in bits of *Cerastium* between the patches of Crocus; give them a good watering, and repeat it till the first rain comes; and as soon as the *Cerastium* begins to spread, train it so as to fill the first 8 inches. Next year the *Arabis variegata* will be the front.

The next row makes a marked contrast being a deep dark blue *Lobelia speciosa* from seeds. Sprinkle the Lobelia seeds very thinly over a shallow box filled with light mould; damp a piece of flannel, and stretch it like a bladder over the box, keeping the flannel damp and warm, till you see the seed sprouting. You know all the rest without my John-Andersoning it. Ten inches you are to allow for the Lobelia; but to get it to cover soon, plant in two rows zig zag, and no more than 6 inches apart.

The third row is to be the softest of all, and all of *Stachys lanata*, which is as hardy as the daisies on the lawn, and spreads much faster than they, creeping along and rooting as it goes. Every little morsel of it taken up in April has roots to it; the smaller shoots to be planted only 4 inches apart, others at 6 inches, and some large pieces as much as 9 inches or 10 inches. This is to cover exactly 15 inches across, and must be set in two rows to get it to cover as soon as possible; but this is such a strong-growing plant, that it might be transplanted thus in January, February, or March just as well as in April.

Every row of a John-Anderson-my-jo-John ribbon must be replanted every spring. But the old woman at the lodge says that a light blue that would beat all the blue Lobelias in the world, and bloom long after they were gone, is the worthy *Viola calcarata*—the most running, the most hanging-down, and the most flowery of all the Violet tribe. To be done exactly like *cerastium* or *stachys*, and to be allowed 1 foot to spread over; then it blooms from May to October in light soil, and carpets the ground. The coldest, the most dreary and most bleak spot in this island is a little to the south-east of Peterhead in Aberdeenshire, close on the sea; and I shall guarantee that none of these first three lines of a ribbon would have lost a leaf there last winter. The *Cerastium* and *Viola* would bloom there

also in contrast; but *Stachys lanata* must not be allowed to bloom in rows.

The next row must be *Perilla nankinensis*—from seeds, of course, to cover 15 inches more or less, to be planted slantingly along the row, in order to half training it. But some of you must give the seedlings to the woman at the lodge. And if you have the love of glare in you, stretch down the next row full of *Calceolaria integrifolia floribunda*, stout old plants; but if you prefer form to colour, and contrast to substance, as florists do, down with the *Calceolarias* to the lodge, and up with a magnificent silver band of *Antennaria margaritacea*, and make it 18 inches wide and about the same in height. You will find it mentioned in my chronicles of last season from Hampton Court, and in almost all the cottage gardens from here to Faversham. The shoots from the stools of last year are now white as snow, rising 2 inches to 3 inches above the surface of the border. You are to take these and their like, year by year, at this time of the season, with 2 inches of root-stem to each, and no more or less. You are to plant them, also, at 6 inches, or 8 inches, or 9 inches apart, according to your stock or their strength; and to make sure of my jo-John, you ought to plant three rows of them to cover the space of 18 inches at once. The flowers are like golden cups set in silver saucers; and if the leaves were green the flowers would tell as much as those of *Calceolarias*. But my plan does not require flowers at all: they may, however, want a row of hidden sticks, and a string in front of them, to keep them upright; but if they are not flowered they will scarcely need it.

The fifth row is to be of two of the oldest plants of all from seeds, hardy and self-sown if you like. The one is purple *Orach*, the other *Persicaria*, plant for plant along the row; or, what would be better still, one row of each, the *Persicaria* being a foot or 15 inches behind the purple *Orach*, which is called in nurserymen's catalogues *Atriplex hortensis rubra*. The old *Persicaria*, as it was designated forty years back, is now called *Polygonum orientale*. Tournefort first discovered this good old annual in a prince's garden at Tiflis, beyond where the siege of Kars was held out against by some of our people, when the rest of our Crimean heroes were in the midst of the fray; and to this day it is the prince of all the hardy annuals, for both it, and the *Orach*, and the rest of the plants on this border, are as hardy as the common crocus.

But behind these, and as like cottage flowers as any, three rows in close succession of old-fashioned *Hollyhocks* will finish the first "ribbon-border for the many" without a pane of glass if you do as I said. But the best work on making ribbon-borders, and the one which prompted me to compete with the author, is the bedding-plant catalogue of Mr. Scott, of the Merriott Nurseries, of which, as you will see in the last JOURNAL OF HORTICULTURE, one blue post stamp will procure a copy. Besides, the catalogue is the best arranged for young beginners of all that I have yet seen. D. BEATON.

TREATMENT OF ARAUCARIA IMBRICATA INJURED BY THE WINTER.

I HAVE an *Araucaria imbricata* about 17 feet high, healthy and strong, and uninjured prior to the frost in December last. That frost killed all the branches for 4 inches or 5 inches from their ends, and the wind has blown twenty or thirty of the dead parts off. Should I do anything to the tree, or what course would you advise me to adopt? I see no alteration in the appearance of the tree except the dead parts. The leader is browned, but I do not know whether it is killed.—J. G.

[Yours is a most important question at this moment. It is now just the time to cut back all *Araucaria* branches whose tops have been more or less killed by the frost. Cut below the frozen part; and if there is a dark brown ring seen on the cut end you must cut lower till no dark brown ring is seen, because the dark brown is the form of death in *Araucarias*, and death is often much deeper or lower down than one might think from the looks of the bark and leaves over it. The leader to be served as side branches, and the best-placed or more vertical bud on the stump must be trained to renew the leader, and encouraged to do so by discouraging all those shoots that might aspire to the leadership. If more than three buds start on a side branch after it is cut, reduce them to three, the three best placed to run out that branch, one straight a-head, and one on each side of it.

This answer applies to every member of the family of Conifers; for if one of every species and variety of Conifer were to lose the leader and the tops of all its branches, nothing more could be done to advantage them so much as attention to these simple rules, and every one of them would renew the leader if thus taken in time. We shall be obliged by a brief account of the losses among your shrubs and Roses—merely a statement of the loss, the different degrees of loss, the soil, situation, and part of the country.]

EFFECTS OF LAST WINTER UPON PLANTS

IN VARIOUS PARTS OF ENGLAND.

(Continued from page 38.)

LINTON PARK.

As your columns, in common with those of all similar publications, have of late recorded the destruction the past winter has caused amongst shrubs, trees, and, in fact, throughout the whole vegetable kingdom, and as the icy king seems to have visited the whole kingdom with more or less intensity according to circumstances, but in all cases more severely than on the average of years, it is not surprising that we hear of much injury done. This was, doubtless, much increased by the condition most plants were in at the commencement of the cold season. A dull, wet, sunless summer had delayed the growth of everything until late in the autumn; and the latter being comparatively mild until an unusually severe frost set suddenly in, and everything being charged with the juices of the growing season, it need not be wondered at their suffering so much. Even those trees and shrubs which had ceased growing, had done so rather by the chills of autumn paralysing their growth than by having ripened their tissue, and the soft succulent condition they were in rendered them an easy prey to king Frost. Many of the plants now complained of as being killed by the winter were not in a condition at its commencement to resist its influence. But we may learn a useful lesson from those which have survived; and by a comparison of the relative positions of plants of the same kind, which in one instance have been killed, and in another have lived almost unscathed, we may ascertain the condition most likely to conduce to a plant's hardihood; for if a *Laurustinus* be killed down to the ground in one place, and scarcely injured in another but a short distance off, we are justified in supposing other plants would have been acted on in like manner if placed in similar positions. And as some districts have been visited with more severity than others, and the injury or destruction has varied accordingly, we hope to have the various reports duly chronicled in THE JOURNAL OF HORTICULTURE. For instance, a lady writing from near Birmingham informs me her Roses are completely killed, and scarcely an evergreen of any kind is left, a similar complaint from the south of Yorkshire, and even in Cornwall the winter has been felt to an unusual degree for that county. But as we may hope to hear from all these places, I will content myself with reporting the injuries we have sustained here (Kent), and also mention those things that have escaped with little or no damage.

In the first place, I may mention that, in common with every other district, we had a dull, wet, cold summer, and the autumn, though cold, was accompanied with less frost than is usual at this season; but some frosty mornings about the end of October injured the *Geraniums* and other tender things on the flower-beds which the rains had so previously bleached and disfigured to a hopeless degree, that the bulk of them were at once cleared away—in fact, it was fairly time, in accordance with the custom of former years. But some few were left; and two beds of *Mangles*' Variegated remained entire in an exposed place in front of my cottage, and, strange to say, these beds looked absolutely better on the 17th of December than at any previous time during the season. They recovered from the October frosts, and, the next six weeks being mild, they grew on and recovered themselves; but a sudden and severe frost set in on that night, and continued unabated for upwards of a month. Now when we consider the mildness of the season preceding the frost, and the growing condition many plants were in at that time, we may easily account for the sudden and disastrous check they received. Some shrubby plants which had stood some winters with us before were making a perceptible growth the last few days before this frost set in. Had this frost been preceded by a period of dry, cold, windy weather or slight frosts gradually checking and hardening vegetation, the destruction would have been much

less. As it was, many plants in a growing state had their juices scaled up the first night with their death-warrant; others imperfectly ripened suffered less in degree, still they were hurt; and as the last few winters had been tolerably mild, many plants had been left out of doors not usually met with there, and these, of course, have suffered most, as will be shown by the following list, to which a few notes on each are appended.

Acacia verticillata.—A fine plant of this, growing against a west wall, flowered beautifully every spring for some years, and in the autumn was thickly set with buds again, but the frost has entirely killed it. A few laurel boughs stuck against it were all the protection it ever received, and it had the same the past season, but to no avail—it is completely killed. A plant of *A. armata*, after lingering on a year or two, was killed the winter before; but the one mentioned above was in robust health up to the time of severe weather setting in.

Abelia uniflora.—A small plant of this has stood against a south wall with very little damage, and with no other protection than a few laurel boughs stuck against it during the severe weather.

Azalea indica.—One or two plants in sheltered positions against a wall very little hurt; but some plants in an open bed are killed to the ground. They were, however, not in good order in autumn.

Berberis Darwinii.—This is certainly one of the most hardy plants we have, and richly deserves a place on every wall. It does not seem to have taken the least harm during the past winter, and at the present time (20th of March) is loaded with flower-buds which in due time will show themselves. *B. Fortunei*.—I have never been able to make much of this. A shabby foliage and slow growth are a poor compensation for the few flowers which it produces. *B. japonica*.—A small plant of this does not seem to have suffered in the least from the winter. Its position, however, is not well chosen, as its foliage suffered even from the little sun we had last year. *B. Bealii* is much like it in appearance and habit.

Camelia.—A large plant of this on the lawn was loaded with flower-buds in the autumn, but they were all killed with the frost, and have all fallen off, and it has shed more leaves than I should have liked to have seen; but those that remain and the wood-buds are all right, proving the plant to be as hardy as the majority of evergreens.

Ceanothus papillosus.—Killed to the ground without the slightest hopes of recovery. A fine plant, had endured several winters, and bloomed profusely in the early summer; but it is lost now. *C. pallidus*, *divaricatus*, or *dentatus*, for I have heard it called by all these names.—It has a bright-shining green leaf, grows rapidly, and flowers sparingly. Some plants in exposed places are killed, and even against a south wall one or two are all killed but the thick main stem, but two plants in a more favoured spot are but little hurt. *C. azureus*.—This is perfectly hardy, only the tip ends of some of the shoots with some of the foliage are hurt, the main plant promising to become as ornamental at the proper time as before. This fine variety flowered twice in the hot summer of 1858 and 1859, once in the early part of June, and again in September.

Coronilla glauca.—Killed to the ground and below the surface in all but one or two very favoured spots.

Cotoneaster Simmondsii.—This broad-leaved variety has stood well against a bleak north wall. It promises to be a useful addition to this class of plants.

Chinese Privet.—A large plant of this, which for some years flowered abundantly in August and September, did not open its blossoms in time to become fully expanded before winter set in, and they are there now. The tree has taken no harm, but it is not likely that there will be any bloom the ensuing summer.

Clianthus puniceus.—A handsome plant of this, growing against a south wall, was in the very worst possible condition to resist frost. For the first fortnight in December its shoots were still advancing, and covered with flower-buds, some of which were expanded. Such a state of things gave little hopes of its enduring the long-continued frost, even when covered up with a double mat; and the result is that it is killed down to within a few inches of the ground, and there is great uncertainty of its growing again. I regard this and the *Acacia* as the most serious losses we have had in this way. Another plant of the same kind suffered in like manner.

Colletia Bictonensis.—This singular-looking plant being removed about a year ago did not prosper well last year, and I fear it is killed. It was quite unprotected.

Cupressus funebris.—One plant in a low situation a little hurt, another in higher and drier ground unhurt in the least. *C. Lambertiana* is as dense and green as it was in October, and is a fine object.

Cistus ladanifera.—Quite hardy, not injured.

Cork Tree.—A fine specimen of this is much injured in the foliage, but we hope not seriously hurt in any other way.

Desfontainia spinosa.—Quite hardy, not the least hurt by the frost, but it is of slow growth, and has not flowered out of doors here yet.

Escallonia macrantha has its leaves browned much where standing as an open standard, but against a wall it has not taken much harm. *Escallonia Monte-vidensis* has lost more foliage than usual, and the tip ends of the shoots are all killed, but the plant has not taken any vital harm.

Eugenia Ugni, and *E. apiculata*.—The first-named is certainly the most hardy, as the latter has lost a large limb or two, the foliage remaining being unburnt.

Euonymus japonicus.—These as open bushes are all more or less killed, and some I fear will hardly grow again.

Fabiana imbricata.—Beautiful as the flowers of this plant are, it will never take a first place as a covering to a wall, the sickly-looking hue of the foliage being sadly against it; but it has stood the winter not amiss, though not seatless, and a small plant of it is killed.

Forsythia viridissima.—Quite hardy, but the tips cut with the frost. There are, however, little signs of its blooming this season.

Garrya elliptica.—The leaves a little blotched, but the plant not seriously injured. Its graceful-looking catkins were less plentiful the past winter than heretofore, owing to the unfavourable summer no doubt.

Griselinia littoralis.—Quite hardy, but rather a slow-growing shrub; and as it strikes freely from cuttings, I dare say, when Mr. Appleby can induce any of our floral friends to try the effects of evergreens for display instead of the ordinary bedding-out flowers, this will come in very handy. A pale green foliage, very thickly set on shoots that promise to bear cutting well. It will, no doubt, be a favourite in that way.

Hydrangea.—Most of these lost the greater part of last year's growth by the wood not being ripened, and leaves still on when winter set in.

Illicium floridanum.—Also of slow growth, but quite hardy. It has not showed flower yet. Against a wall it stands the winter well.

Jasminum.—These are quite hardy; and the *J. nudiflorum* is now flowering instead of at Christmas.

Laurus aromatica seems hardy but makes no progress. If it would only grow freely it would be a handsome shrub.

Lonicera flexuosa, or Evergreen Honeysuckle, has lost more foliage than usual; but is alive at the base of each shoot, the tips being killed.

Magnolia grandiflora and *M. Exmouthi*, very much cut and have lost nearly all their leaves. Some plants growing against a south wall had several unexpanded blossoms when the severe weather set in at the middle of December; but, of course, they have been all killed, and the plants, by losing so much of the tips of the shoots, will be crippled for the whole of the year, that we can hardly expect bloom in any quantity for two years.

Myrtle.—Much injured, but not vitally. The foliage nearly all gone; but, by being spurred in, the plants will do very well again.

Pampas Grass.—Some plants quite killed, others nearly so; and the flowers of 1861 will assuredly be late, unless the season be a very favourable one indeed.

Phygelius capensis.—Standing against an east wall this plant has suffered less than many, and promises to be a useful auxiliary to our list of half-hardy, half-shrubby, and half-herbaceous flowering plants.

Pomegranate.—We have only a very small plant of this and recently planted, which seems to have suffered to a hopeless degree; but this is no guide to the plant's hardiness or contrariwise.

Pernettya mucronata speciosa.—A pretty small-leaved shrub, quite hardy and untouched by the frost. This seems as hardy as the common Box.

Rose.—This extensive family may be dismissed without going into names, further than that all the Tea kinds are killed; but hardy China and Hybrid Perpetuals are alive. The China, however, are in most cases cut down to the ground, but are growing again. A Banksian or two against open pillars are either killed

outright or so far injured as to be useless; but our loss amongst the Roses here is trifling, compared with what is reported elsewhere of the Hybrid Perpetuals, these being unhurt, and some of the Teas on standards in dry situations have escaped.

Stawtonia latifolia much cut but not killed, although growing against a south wall.

*Veronica*s of the New Zealand species, as Andersoni, Sieboldi, Lindleyana, and others, in most cases killed entirely. Some against walls in favoured places may perhaps shoot up again from the bottoms or from the old stems that show a little life in them.

Weigela rosea.—This appears quite hardy, and is shooting as freely as ever from all but the extreme tips of last year's wood, but it is not likely to bloom so freely as in former years.

Yuccas.—These interesting plants have suffered in a certain degree, their leaves being broken, and the plants altogether seem much injured in appearance.

The above list represents the damage we have sustained in the class of hardy and half-hardy shrubs, as all our Bays, Laurustinuses, Aucubas, and others have escaped any important injury except in some cases where Laurustinuses had formed part of a clipped hedge, and the late shoots of last year are killed, and one or two other plants have suffered in like manner where so situated. The Pinuses have, in most cases, escaped. None of the Deodars are in the least hurt. *Araucaria braziliensis* or *Cunninghamii* looks badly, but it has always done so at this season, and a fine plant of *Wellingtonia* is browned a little on the east side where the morning sun first caught it. *Cupressus Lambertiana* is as green as a Holly, and all the other Pinuses seem untouched by the cold.

Amongst plants of humble growth everything not established as hardy has been killed. The hardy *Verbena pulchella* and its variegated compeer are both destroyed, as is also the *Linum flavum*; and what few *Calceolarias* were left out have all perished. This is, doubtless, owing to the small quantity of snow we had—merely sufficient to colour the ground; but the severity of the frost told in cold pits as well. The *Calceolaria amplexicaulis* cuttings in a pit with a wooden shutter over them mostly all perished, while the more woody varieties of *Calceolaria* scarcely received a check, or at most lost very few plants; and the variegated *Arahis* growing in the same place is equally unhurt. I may also observe that the outside plants of this most useful dwarf edging plant seem as hardy as a Primrose, not being in the least injured by the weather; but some plants have succumbed to the cold. Very few *Catchflies* are alive, and old plants of *Cheiranthus Marshalli* are, in many instances, dead. Stocks are also entirely killed, and many Wallflowers are sufferers also; and I have no doubt but a close examination will reveal other losses in this way.

In the kitchen garden Broccoli are very scarce; almost all the tall plants are entirely killed, but some dwarf kinds are left. Winter Spinach is all but gone; and Parsley, which usually survives any amount of cold, has died away in a great measure at the root. Cauliflower plants where not well secured have suffered sadly. Cabbage plants are better; and though Greens of the various kinds have been scarce, still the plants have not been so completely killed as has been the case in some places. Turnips we have none, but their absence is not entirely owing to the weather, as our supply is generally from another source. Sweet Herbs have perished almost wholesale. Thyme, Savory, and Mint seem all gone, and Sage very much cut. Some other losses may, perhaps, be added to these, but the list is already extensive enough; and though no one wishes for so severe a winter again, it has not been half so bad as the summer which preceded it. On the contrary, the frost has certainly improved the land for tillage purposes, and with a favourable season we may hope to have a more pleasing report to make another time.

J. ROBSON.

KILMARNOCK PANSY SOCIETY.—On the 12th inst. the West of Scotland Pansy Society held their first Meeting. The business was, for the most part, of a preliminary nature. A few good flowers were exhibited, the best of which was General Neil (Smith's), a first-rate yellow ground flower, which can hardly be beaten in the beginning and end of the season. The Society will hold fortnightly competitions throughout the season; but the most important part of the Society's operations was the appointment of ten of its members (five a quorum), to adjudicate on the merits of any new varieties that may be forwarded by members or others. From the well-known abilities of that

Committee, and the ordeal all flowers that are submitted must undergo, it will be impossible for anything not in advance of existing varieties being recommended or awarded a certificate of merit. This branch of the Society has been attached with the view of checking the practice of sending out worthless varieties, which has latterly become far too common an occurrence. Single blooms may be recommended as such; but three blooms must be submitted at once or in succession to obtain a certificate of merit. The West of Scotland has long been characterised as a great Pansy-growing district; and many of the leading varieties owe their existence to the growers of that beautiful flower in this locality; and were other districts to adopt a similar course, that would materially assist the West of Scotland Society in their laudable endeavours to further improve the Pansy.

CULTURE OF THE GRAPE VINE.

(Continued from page 44.)

THE borders should be made and finished as early in the autumn as possible, that the soil may be settled down to its proper level before planting time. Some authors recommend planting after the Vines have made their spring shoots in boxes, baskets, or pots. I have tried that plan, but I found that the roots could not be so well spread out in the soil without injuring some of the newly-made ones. I, therefore, greatly prefer the planting just before the buds begin to swell: in that state the soil can be shaken out of the ball, and roots disentangled without injury, and spread out in a proper manner in every direction. On this point, however, I shall write more particularly under the head "planting."

PROCURING THE PLANTS.—If the cultivator intends to purchase his young Vines from a nursery, he ought to go to the nursery early in the autumn, and choose the plants himself, marking them on the spot at once. Well-grown one-year-old plants raised from eyes are the very best for the purpose. If they are older the roots are so coiled round the sides of the pots that they cannot be uncoiled without some being broken, cracked, or bruised. Nurserymen now grow one-year-old Vines quite strong enough for planting permanently. The Vines should be sent to the purchaser as soon as their leaves are fallen—not later certainly than the end of October.

As soon as they arrive they should be unpacked carefully, so as not to crack any of the shoots. Let them then be pruned to such a length as may be required. If they have to be brought through a hole in the front sill of the house, then prune them so as to leave from four to five eyes within the house; but if they are to be planted inside, then cut them down to three eyes. When all are pruned then plunge the pots either in leaves, old tan, or ashes, against a south wall, where they may remain till the planting season. If the Vines are intended for the open wall they may be planted out at once, protected with litter over the roots. By being pruned in autumn there is no danger of bleeding, which they are liable to do if pruned just before they are planted.

Propagation.—Some gardeners raise their own Vines, but unless they have plenty of space or a house especially well adapted for the purpose, I consider there is no saving in rearing their Vines at home. Better have them from a respectable nurseryman—one, of course, that can be depended upon to send them true to name. However, as my essay would hardly be complete without a brief notice on propagating the Vine, I had better give the right way to do it. The Vine is almost as easy to strike as a willow. It may be propagated by layers, by lengths of two or three-year-wood, by a small piece of two-year-old and two or three buds above, and by single eyes of the last year's growth.

Layering is, or ought to be, quite discarded; for when a layer is cut off from the parent stool, it receives such a check that it requires two or three years (even with the best management), before it recovers the separation.

Old Shoots also require considerable care to make them push roots sufficient to support a strong young shoot. The two-year-old wood cut off a few inches below the point where the young wood of the same year has pushed from makes good cuttings, and with little care makes good plants the following year. I have grown good Vines by this plan fit to plant out the following year. The only objection is, that a stump always remains at the base of the Vine, which is liable to decay sooner on that account.

I now come to *single eyes*. These approach the nearest to seedlings, and for permanency form the very best plants. In saving wood for buds to raise young Vines, avoid coarse strong shoots; choose rather such as are round and of a medium strength, with as little pith as possible, and also choose the cuttings from Vines that have been forced early—not only because the wood is sure to be well ripened, but also the buds in the natural course of the season will be more easily excited to start early. Also prefer the buds that are nearest to the preceding year's wood, taking care, however, that each bud is plump and sound. Take off the shoots intended to be propagated as soon as convenient, label each bundle correctly, and lay them in by the heels on a shady border. Towards the middle of December place some soil, composed of fresh good loam, leaf mould, and very rotten dung, in equal parts, in a warm shed to dry. Have ready a sufficient number of pots $3\frac{1}{2}$ inches wide. Then about New Year's Day bring the cuttings inside, and cut them into short lengths, one bud to each length. One inch in length will be sufficient. The part behind the bud is then reduced in thickness, and cut off in a slanting direction towards the ends, and the part under the bud horizontal. The cutting will then have this appearance—

Fill the pots nearly up to the brim, and with a small dibble insert one bud or eye in each pot quite overhead. To prevent mistakes do all one kind first, and place a label or number to that lot before commencing with the next variety. This method of putting the eyes at the first in separate pots is much better than placing a number in a shallow pan, or wide-mouthed pot, because in repotting not a single root need to be injured. When all are potted and securely labelled, then place the pots in a propagating-house on a platform covered with sand. Under the platform there should be hot-water pipes, and there should be a sufficient extent of pipes to get up a heat of 70° . At first, however, a temperature of 50° will be sufficient, and raise 5° every week till the maximum is reached. During all this time a moist atmosphere should be kept up in order to cause the eyes to swell and break kindly. In a month or six weeks every bud will be breaking through the soil and forming roots downwards. Keep the soil regularly moist, but not wet, for too much water would cause some to damp off. As the leaves begin to expand more water may be given.

Examine a pot or two occasionally by turning out the ball carefully, and as soon as the roots reach the sides of the pots generally, then place a lot more of the compost in a warm place to air it. Cold soil at this stage would chill the young roots and check their growth. As soon as it is sufficiently aired, then begin to repot the young Vines, being always careful to keep them from draughts of cold air. I prefer, if possible, to repot them in the propagating-house itself.

Shift them into six-inch pots, giving plenty of drainage. These pots will carry them on growing till the middle of May, when a second repotting may be given them, placing them in eight-inch or nine-inch pots. They will now require more room and plenty of air, and liberal supplies of water, and liquid manure. Place a tall stick to each Vine, and look sharp after red spiders and destroy them. After a sunny day use the syringe freely, which will keep down insects and encourage growth.

In these pots they may be allowed to finish their growth—I mean such as are intended for planting out. They should make shoots in them 8 feet or 10 feet long, and as thick as a penholder.

If it is desired to fruit a few in pots, then give such another repotting in June into fourteen-inch pots, using more loam in the compost to give solidity to the wood. Vines for this purpose should be stopped when 10 feet long, and should have more light and space to each. I shall, however, give a more full description on this part of the subject under the head "pot culture."

By starting the eyes into growth so early as described above, the cultivator will have the advantage of getting his Vines into strong growth early, and thus be enabled to obtain good plants with well-ripened wood before the summer is over.

(To be continued.)

T. APPELBY.

TRAINING PLUM TREES—PEACH TREES UNDER VINES.

I HAVE your book "Fruit Gardening for the Many," and I find it very useful; but with regard to pruning the Plum trees (especially trained trees), I do not quite understand the mode adopted. Is it laying in all the side shoots (except breast shoots, &c.), without any shortening? and if so, how are the second year's shoots to be obtained, as there generally is but one wood-bud at the end of the shoots, and that would cause nakedness? Should the shoots be spurred in?

Can Peaches be grown to advantage in a house covered with Vines?—J. G., *Chelmsford*.

[The side shoots of Plums should be laid in, choosing those of medium strength, and cutting away the redundant ones if very strong or very weak. These should be far enough apart to permit of light acting freely on them. In general these side shoots should all be shortened less or more. This causes every bud on a young shoot to break, and most likely these will furnish little spurs which will bear for years. If they do not form a spur naturally, but grow on into breastwood shoots, these should be stopped when 3 inches or 4 inches long, and stopping continued a little to arrest mere rampant growth, to let the sun to the base-buds, and to cause such concentration of organised sap there as to make them assume the character of fruit-buds.]

The Peaches cannot be grown to advantage in a vinery, if the main stems of the Vines are closer than from 4 feet to 6 feet apart. The latter distance would be the best.]

FORCING.

KIDNEY BEANS.

A LATE crop of these may be obtained in autumn by sowing in a cold pit in August, and covering with glass at the end of September. A later autumn crop may be obtained by sowing in pots in September, and placing them where artificial heat may be given them by the middle of October. Fair spring crops may be grown in dung-beds after the middle or end of March. Seeds sown in heat on the 1st of April, plants hardened off, and turned out into a cold pit under glass, will produce freely from the end of May. Seeds sown in small pots, three in a 60-pot a fortnight later, may be turned out by the second week in May for the first out-door crop, receiving only the protection of a green branch on planting. All through the winter it is next to lost labour to attempt growing them without the assistance of fire heat in some shape or other. From November to January they need about ten weeks from sowing the seeds to gathering the pods. From January to May from eight to seven and six weeks. In the winter months I prefer growing in six or seven-inch pots, placing four or five seeds in a pot after it was three-parts filled with sandy loam and leaf mould. The soil must neither be heavy nor rich at this dark season. I have mentioned so many seeds in a pot, but I seldom sow where they are to grow at once. Economy in space is secured by sowing rather thickly in a moveable box, and transplanting when the first leaf shows above the seed-leaves. The plants are thus rendered more sturdy and more fruitful. At this season we stop none, which tends to promote earliness. Such plants when growing freely are earthed up with light soil a little richer, to within half an inch of the rim of the pot. As we get into January and February, we use larger pots, from 8 inches to 12 inches in diameter, much stronger and richer soil, and about four plants to a pot; and after that season we nip out the terminal bud when a joint is made above the seed-leaves. These pots will do admirably in any sunny spare part of a house, where the night temperature ranges from 55° to 60° , with from 60° to 70° during the day, and a rise of from 5° to 10° more in bright sunshine.

The plants are liable to the attacks of the thrips. The best preventives are plenty of manure waterings, and frequent syringings with clear soot water, at a temperature of about 80° . The thrips, however, even then may appear at times, and, therefore, it is best to grow them, when convenient, in a pit or house by themselves. Then, too, a bottom heat of about 80° may be given, in which they greatly delight.

A few lights will yield a long daily supply, and if cleared of old shoots, and no Beans allowed to get old, and fresh top dressings and manure waterings given, there is hardly a limit to the time they will bear. I have frequently had the same plants in bearing from January to June; but I would not advise such

a plan as being anything extra economical. Nothing is more improved by forcing, the Beans if young enough eat so crisp.

Of kinds I prefer the Newington Wonder, chiefly when to be cooked whole. Of all others I prefer in-doors and out of doors, the China Dwarf, called also Robin's Egg. The Fidler's Forcing, the Sion House Forcing, and the Cream-coloured Dwarf, are also very good. I have also grown heavy crops of the White Dutch Runner in pots, by nipping in the shoots. They thus became little balls of pods and flowers.

BASIL

when wanted green in winter should be sown in September, and kept in a hothouse all the winter. When a good quantity is wanted green and for drying in summer, sow in a hotbed in April, prick out the seedlings, and plant out in a warm border at the end of May. If the season is cold place a spare sash over the plants for a few weeks.

CAPSICUMS

in the shape of Chillies, and other kinds of various shapes, sizes, and colours, are much liked by some families, both when ripe and green. The great proportion do best treated as tender annuals. Sow in light, sandy soil, and leaf mould, about the middle of March, and place in a hotbed. When 2 inches high prick out half a dozen round the sides of a four-inch pot. In a fortnight, or three weeks, give each of these a similar-sized pot, and repeat as necessary until each plant has a six-inch or eight-inch pot; and for ripe fruit keep these pots under glass in any forcing-house until the autumn; and for green fruit, instead of giving such large pots, turn out the plants in front of a wall or hothouse in the middle of June. Green fly is apt to attack them. The smoke of a few of the Capsicum pods burned or a puff of tobacco will settle the insects.

CARROTS.

The best for forcing are the small, short French and the Early Horn, and a little of the Early Horn Scarlet. Young Carrots may be obtained through most of the winter by sowing these sorts in beds in August, and giving protection when needed; but even at the best they are much harder and woodier than nice young plants raised in a moderate hotbed. I have found little is gained by making the bed before Christmas. Even then a bed for a frame should be from 2½ feet to 3 feet in height, if one part dung and two parts leaves; soil 6 inches deep, and light and sandy, rather flat, and within 6 inches of the glass. Make the surface smooth. Sow Carrot seeds rather thickly, either in rows 3 inches apart or broadcast, and a sprinkling of Radishes to draw early; beat slightly down, and cover with a sprinkling of dry sandy soil. The heat should be from 50° to 55° after the Carrots are up. Unless very thick, I thin but little; for as soon as the Carrots are a quarter of an inch in diameter they will do for soups, and the larger may be left to grow big enough for dishes. A great number may thus be drawn out of a two-light box. Of course, if you wish each Carrot left to be a fair size before any are used, then you must thin out so as to leave them 3 inches or so apart; but that I consider great waste. Air should be given early at all favourable times, but when quick returns are wanted, too much should not be given, nor left too long on. If the bed is allowed to get cold the Carrots will be little more crisp than if grown in the open air. If Radishes are thus sown on the bed they must not remain too long, or they will starve and shade the Carrots. Whilst young, any watering should be done with water not below 60° to 70°.

CELERY.

This may be considered forced when small, fresh, white heads are wanted for soups in June, and good heads for the table in July and August. For the first the seed should be sown in a hotbed by the 1st of January, the plants be pricked off and by the middle of April be planted out on a mild hotbed 6 inches apart; be encouraged to grow quick by shutting in sun heat, and giving a little shade in bright sun, and earthing up with dry leaf mould as they grow. The same plan may be pursued for the first crop at the end of July, only the plants should be moved to the trenches in the middle of May, and a little shade given on very bright days, and a little protection on cold nights. If properly attended to in watering there is no danger of this early Celery bolting, or throwing up the flower-stalk, if the earthing up does not take place more than a month before the heads are wanted. The Dwarf White is the best for this

purpose. For main crops March and April are soon enough to sow.

CHICORY.

Young leaves of this are sometimes obtained in winter by sowing thickly in pots in a hothouse, and cutting the plants over as we do Mustard and Cress. A nice blanched salad is obtained from roots either stored or taken up as wanted in winter, the produce of seeds sown in rows 15 inches apart in May. These packed with their heads uppermost in earth in pots or boxes will furnish a good produce in any dark place where the heat ranges from 40° to 50°. When much above the latter, the leaves get thin and flaccid. When no dark place is accessible, fill a pot or box, and put another of the same size over it, clapping some moss or clay putty between the pots, and stopping up the hole to exclude light. Dandelions make a good substitute. I have been glad to dig them up in severe winters.

R. FISH.

(To be continued.)

REPORT ON THE GARDEN PEAS,

GROWN AT CHISWICK DURING 1860.

By ROBERT HOGG, LL.D., F.R.H.S., *Secretary to the Fruit Committee.*

(Continued from page 29.)

28. **Matchless Marrow** NOBLE, COOPER, & BOLTON.

SYN. *Milford Marrow* LAWSON & SON.

Stradsett Marrow FLANAGAN & SON.

Plant 5 feet to 6 feet high, of strong and robust habit of growth. The stem is always simple, and bears from twelve to sixteen pods. The pods are generally in pairs, rarely single, and contain from six to seven very large Peas. The ripe seed is large, uneven, variously and irregularly shaped, and of a white and olive colour mixed.

Sown February 19th; bloomed June 13th; slatted June 23th; ready for use July 15th.

This is a great bearer, and produces large, plump, well-filled pods, which come into use four or five days after the Early Green Marrow, and ten days after Prizetaker; but it is a tender variety, and during the past season did not fill well, nor were the pods freely developed.

29. **Garbutt's Amazon** FLANAGAN & SON.

SYN. *Denger's Early Prolific Green Marrow* NUTTING & SONS.

Plant a strong robust grower 5 feet to 6 feet high, having a simple stem, which produces not more than six pods. The pods are either single or in pairs, and contain six large Peas in each. Ripe seed white and olive mixed, large, uneven, variously and irregularly shaped.

Sown February 19th; bloomed June 19th; slatted June 29th; fit for use July 20th.

This is very much in the way of Matchless Marrow, but comes into use five or six days later. It is also much less productive, and the pods, which are few, fill indifferently, so that it is not a desirable variety. Is it not the old Tall Green Marrow?

30. **Sutton's Berkshire Hero** SUTTON & SONS.

This is a much taller and stronger grower than the preceding, and five or six days later in all its stages. The plant is 7 feet high, and produces eight or ten large pods, which contain from six to seven very large Peas. The ripe seed is larger than that of the preceding and of Matchless Marrow, uneven, variously and irregularly shaped, and of white and olive colour mixed.

Sown February 19th; bloomed June 25th; slatted July 3rd; and ready for use July 25th.

IV. PRUSSIAN PEAS.

Ripe seed small, almost round, smooth; skin thin, blue. Foliage dark green, blotched.

31. **Groom's Superb** LAWSON & SON.

SYN. *Blue Spanish Dwarf*; *Blue Fan*.

The plant grows from 18 inches to 2 feet high, and has a simple stem, bearing from eight to ten pods. The pods are single or in pairs, in about equal proportion, and contain six to seven Peas in each. The ripe seed is small, round, and pale blue.

Sown February 19th; bloomed June 16th; slatted June 25; fit for use July 14th.

This is now almost entirely out of cultivation, being surpassed

by several other varieties of superior merit. It is really not worth perpetuating.

32. Woodford Marrow NOBLE, COOPER, & BOLTON.

Plant of a strong and robust habit of growth, having very dark bluish-green blotched foliage, and a stem $3\frac{1}{2}$ feet high, which is sometimes simple, but generally branched at about half its height from the ground. The pods number about eleven on a plant, and are produced singly or in pairs; when ready to gather they are rather flattened, but as they become ripe they assume a roundish shape. They contain on an average eight Peas in each, and these are of a very dark olive green colour, rather thick in the skin, and very closely packed, so much so as to be quite flattened where they come in contact. The ripe seed is very dark blue.

Sown February 19th; bloomed June 14th; slatted June 26th; and fit for use July 14th.

On account of its fine dark green pod this is an excellent Pea to grow for market; but it is one that requires to be very carefully selected when grown for seed, as it has a great tendency to degenerate back to the Blue Prussian, from which it has evidently been raised.

33. Batt's Wonder..... BATT, RUTLEY, & SILVERLOCK.

The plant is of a strong and sturdy habit, with a thick stem $2\frac{1}{2}$ feet high, generally simple, but sometimes branching, and having large dark green foliage. The pods are produced in pairs, on an average of from twelve to eighteen on each plant; they are curved like those of the Scimitar, and contain from nine to eleven good-sized Peas. The ripe seed is small, dark bluish-green, of the colour of that of the Woodford Marrow.

Sown February 19th; bloomed June 16th; slatted June 28th; and ready for use July 16th.

In the trial of 1859 this was found to withstand the dry weather better than any other variety; but in 1860 it suffered from the coldness of the season, and the pods filled irregularly. It is a very excellent and productive kind, as much so as the Scimitar, and the pods and Peas are of the same dark dull bluish-green colour as those of the Woodford Marrow.

34. Blue Prussian NOBLE, COOPER, & BOLTON.

Plant not robust or strong in its habit, having a stem 3 feet high, which is sometimes branching, and with dark green blotched foliage. The pods are generally in pairs, from twelve to sixteen on each plant, and contain about seven closely packed Peas. The ripe seed is blue, small, and almost smooth.

Sown February 19th; bloomed June 16th; slatted June 28th; and ready for use July 16th.

This is a very old and popular variety, much used for extensive culture in fields and market gardens on account of its great fertility—a character which it maintains superior to any of the other blue Peas, most, and indeed all, of which during the past season have exhibited much less hardy constitutions.

V. IMPERIAL PEAS.

Ripe seed large and irregular in shape; skin thick, blue. Foliage large, dark green, and blotched.

35. Fairbeard's Surprise..... NOBLE, COOPER, & BOLTON.

The plant is a free but not robust grower, and always with a simple stem, which is about 5 feet high. The foliage is bright and not dark green, like the other varieties of this class. The pods are generally single, but sometimes in pairs, and are from eight to ten on a plant; they contain from seven to eight good-sized Peas. The ripe seed is somewhat oval, of a pale blue colour.

Sown February 19th; bloomed June 7th; slatted June 20th; and fit for use July 9th.

This and Fairbeard's Champion of England were originally taken from the same pod, the former having a round and the latter a wrinkled seed. It is the earliest of all the round blue Peas, and very superior in every respect to the following, which comes into use two or three days later.

36. Harrison's Glory..... NOBLE, COOPER, & BOLTON.

The only distinction between this and Harrison's Perfection is the blue-coloured seed, that of the latter being white: they differ in no other respect, being of the same height, equally productive of pods, which always fill very badly, and both come into use at the same time.

(To be continued.)

POMOLOGICAL CLEANINGS.

GRAFTING WAX.—Take 27 ozs. of common yellow rosin, melt it gradually so as not to drive off the turpentine. When reduced to the consistence of a syrup, add 10 ozs. of alcohol, shake them thoroughly together, and pour the mixture at once into a well-stopped bottle. When the graft is inserted and tied in its place with a strand of matting in the usual way, cover the surface of the whole with this varnish with a small painter's brush. Such varnish may be used in any weather, and is neither affected by heat, cold, nor wet.

FIRST PLANT YOUR ORCHARD.—He who puts off planting an orchard till a more convenient season than the first "planting season," is like him who waited on the bank of a river for all the waters to pass off, reasoning that a stream running so rapidly must soon run dry. So some people imagine that next year they will have more time to set an orchard, not counting that another year usually brings along with it an increasing amount of cares. Many a man has grown grey with just such resolves as "I will plant another year;" and to-day is farther than ever from doing it. Plant trees first, and cultivate them, and in a few years your orchard is soon producing abundant crops, while your dilatory neighbours are "just going to plant." You can build a house in a year, but not a full-grown orchard. The best interests of many a one are often delayed, hoping to have a more "convenient season." I know of many such cases. I wish I knew of less. Under the present system, the west is supplied from abroad at a great expense, when we ought to supply ourselves and others with all needed fruit. One hundred apple trees of good fruit, under good cultivation will be worth one thousand dollars when they are ten years old.—(D. C. S. in *The Prairie Farmer*.)

STRAWBERRY FROGMORE LATE PINE.—Fruit very large, conical and cockscomb-shaped; broad and flattened at the stalk, where it is glossy like the old Pine. The seeds are numerous, not deeply imbedded. Skin glossy, bright red, becoming dark red, and almost black when very ripe. Flesh tender and very juicy, red throughout, richly flavoured, and with a good deal of the Pine aroma when well ripened. This is a late variety and a most abundant bearer. The fruit is produced in very large clusters, and comes on in succession, generally one-half of them being unripe. The scapes are very strong, stout, and branched twice and thrice compound. This very late and valuable variety was raised by Mr. Ingram, of Frogmore.

STRAWBERRY CULVERWELL'S SANSPAREIL.—Fruit medium-sized, long, conical, uneven, and furrowed in its outline. Seeds not deeply imbedded. Skin a very dark red, becoming almost black when it ripens. Flesh very firm and solid, red throughout, and very richly flavoured. This is a capital bearer, and an excellent late variety.

CULTIVATION OF TRUFFLES.

In answer to your "OLD SUBSCRIBER'S" question respecting "Truffles" in your Number of the 16th inst., I beg to state that thirty-five years ago, when at school at Ramsbury, in Wiltshire, I several times accompanied a "Truffle hunter" in his search. My object was rather to observe the instinct of his dog than the nature and habits of the fungus; but some accidental knowledge was obtained. The Truffle was found at the roots of the trees in huge Fir plantations, the property of Sir Francis Burdett, covering the sides of the hills which flank the vale of the Kennet in that part. The fungus was generally found from 6 inches to 12 inches under the surface, sometimes deeper. The substratum of these hills is chalk, the staple loam, and shallow in general; but in the plantations of many years' growth an artificial staple had formed of a light covering mould from the deciduous leaves to a depth considerably greater than that of the soil on the unplanted sides of the hills. In this the fungus was found, generally, I think, on the outskirts of the plantations. A knot of them was usually found together, and the "Truffle hunter" left a root or two for further propagation. There can be no doubt that it would increase by transplantation to a suitable soil, but I never tried it.

Loudon in his "Encyclopædia of Gardening," third edition, 1825, makes the following extract from the "Edinburgh Encyclopædia," No. 4348—"Culture" of the Truffle. "No attempt," Neill observes, "it is believed has hitherto been made to cultivate Truffles; but of the practicability of the

thing there seems no reason to doubt. In their habits of growth, indeed, they differ essentially from the Mushroom, but it is certainly possible to accommodate the soil and other circumstances to the peculiar nature of the fungus. It has been said that the tubercles on the surface of Truffles are analogous to the eyes or buds of potatoes, and that they have been propagated like potatoes by means of cuts furnished with tubercles. It may, however, be suspected that the pieces thus planted contained

ripe seeds. Truffles, we may add, seem to delight in a mixture of clay and sand; and a moderate degree of bottom heat, such as is afforded by a spent hotbed, might probably forward their vegetation."

Perhaps some others of your readers may give information as to the habits of Truffles in parts of France and in the German forests, where they are found, I believe, in large quantities.—HERBERT RANDOLPH, *Tilbury House, Bruton.*

REDLEAF AND ITS GARDENING.—No. 3.

(Concluded from page 27.)

Fig. 5.—REDLEAF—The Fernery.

In continuing the remarks on Redleaf, we now come to a portion of the grounds which until very recently was but little regarded as a portion of a well-arranged garden—i.e., "the Fernery." Our present engraving, No. 5, only gives an imperfect idea of it, though correct enough at the point taken; but Ferns, taken collectively, present less to make a picture than do most plants, though individually, perhaps, they are second to none for their beauty and graceful appearance. Suffice it, however, to say that this fernery consists of a sloping bank, with large stones jutting out covered with moss, and amongst them is an excellent collection of hardy Ferns. The bank which composes this fernery forms also a boundary between this and another portion of the grounds. A covered walk curves past this fernery—the covering tending to shade some of the plants

nearest the base of the bank. A botanist, or one well versed in British plants, would here find materials for an hour's close and ardent inspection, as all the kinds seem in excellent health.

Engraving No. 6 is a view of the grounds in continuation of the Rock Garden to the south; the dressed ground running to a considerable distance in that direction, and eventually opening into the park, which is also bounded by a piece of water or lake. This vista is open from the mansion, and all tall-growing trees have been kept away from this line; but flanking it on both sides are some fine specimens of Conifers, both in the dressed grounds, and also planted singly in the park with suitable fences around each. Amongst others in that way I noticed *Picea cephalonica*, a fine tree; *P. Douglasii*, nearly 60 feet high, but, being in a very exposed place, was browned a little by the

frost or wind; *Pinus montezeuma*, a fine silvery grey species; *Abies Brunoniana* was, however, too tender to endure a winter like the past; several specimens of *Picea Webbiana*, and some seedlings from the larger trees of it, seemed to be hardier than the parent; *Pinus ponderosa*, in the character of a timber tree; and in a sheltered portion of the grounds was *Cupressus majestica*, a fine tree; *Juniperus sinensis* pretty, and some *Cedrus deodara*, 36 feet high, others 48 feet, but nothing shows a greater diversity in habit than this tree. A fine *Wellingtonia* planted in the park, 12 feet high was associated with a singular adventure that befel it when it was first planted out. A little boy (who, no

doubt, in after life may have an eye for the beautiful), took, a fancy to this tree as a pretty plant for a pot, pulled it up, took it home, and had it a week or two in a garret window, until Mr. Cox, hearing of it, recovered and replanted it, but, of course, not without the loss of what he considers a season's growth—some two or three feet. Nevertheless, it is now a fine, promising plant.

Independent of the features above given, there is a Dutch Garden on the strictly formal style, so characteristic of that school. Shut in on most sides by high boundary shrubs, it has a billiard-room on one side, and on another side, not joining but

Fig. 6.—REDLEAF—View from the Rock Garden down the Lawn.

at right angles to it, a conservatory. The latter, however, scarcely deserves that name as it is now applied, for its front has more the appearance of a cottage with a thatched roof, the side front only being glass glazed in lead-casement fashion. Fine flowering plants are not kept here, but it was well filled with plants of good foliage. Amongst which were two fine plants of *Araucaria excelsa*, *Rhododendron Falconerii*, with a large foliage; *Cupressus californica*, *C. Goveniana*, with its clouds of pollen; *Desfontainia spinosa*, a fine plant, which flowers beautifully at the proper time; *Illicium floridum*, and other things, all seemed in good health, notwithstanding the dark roof they were living under. The garden in front of this house was composed of square, or rather diamond-shaped beds divided by walks of brick with edgings of the same. These beds were in most cases planted with early spring flowers, to be followed by bedding plants. Several edgings were of Dog's-tooth Violets; some had Tulips, others Crocuses, and a *Silene compacta* seemed also a favourite. The outer border of this garden has herbaceous plants, of which there was a fine collection, while choice *Rhododendrons* and other things formed the background; and not the least interesting object was a fine *Camellia pæoniiflora*, 10 feet high, and another of the old double-striped, both of which had been out of doors for something like an ordinary lifetime. After a fine summer they bloom beautifully, but this season buds were scarce. *Araucaria Cunninghamii* was not so much at home, but many of the Indian and Sikkim *Rhododendrons* were in robust health, and some Indian Azaleas were also equally good. Some high trees might, however, be of some service to them as shade on the south, as well as on other sides.

The irregularities of the ground are rather inconvenient to the kitchen garden, which inclines rather steeply to the south-west; it however appears to be very productive. A range of pits heated by a caupon boiler was hard at work, and, of course, full of things wanted now and hereafter. This compartment, how-

ever, was shut off from the kitchen garden, as also was another enclosure which contained two plant-houses well filled with everything that is gay and useful at the present season. These houses are about 100 feet long and rather lofty, with a short north light; the back wall being covered its whole length with what I considered the most remarkable object in the place, being entirely covered from bottom to top, and also the greater part of the north light, with *Camellias* in robust health, and in the early part of March in full bloom. This splendid wall contained hundreds of well-expanded blooms all out at one time, with thousands more to come; and so healthy and growing were the plants, that Mr. Cox says he has at times been obliged to cut wood out of them enough to make faggots. Certainly nothing could look better than most of them did; even *C. reticulata* was flowering as freely and in as good health as the other kinds are often seen elsewhere. A fine striped kind, called in compliment to the former spirited occupier of this place *Wellsiana*, was a mass of bloom. Others kinds were scarcely less so, and the whole looked handsome. A narrow border at their base was planted with Ferns, the remainder of the house being occupied with a stage and flowering plants; amongst which were several *Rhododendrons* of the Sikkim breed, *R. ciliatum* being about as free a bloomer as any. *Cinerarias*, Azaleas, bulbs, *Cythsuses*, and the other plants usual at this season, were also in abundance, and some plants of the *Solanum capsicastrum* were showy with yellow berries; but the *Camellias* were the great attraction, and a wall 14 feet high and 100 feet long covered with this lovely flower is an object we do not meet with every day, and of itself deserves going a long way to see. I confess I was as much struck with it as with any of the other features of this fine place, all parts of which seemed in excellent order, and reflected great credit on Mr. Cox, whose courtesy in pointing out particular objects, and general kindness in affording every information, it is only right here to acknowledge; and

I have no doubt but with spirited owners like its previous and present one, and the assiduous care of a culturist like Mr. Cox, Redleaf will continue to occupy that prominent position in gardening matters which it did in the early Numbers of Loudon's "Gardener's Magazine;" and to the lover of artificial scenery, carefully worked into the form that Nature often puts upon it, Redleaf will always be an attractive place.—J. ROBSON.

WORK FOR THE WEEK.

KITCHEN GARDEN.

KEEP the hoe at work amongst all early crops. *Asparagus*, plant the young plants in beds that have been deeply trenched and well manured. The roots to be lifted carefully with a strong fork, and, after planting, a good supply of water to be given to settle the soil about them. *Beet*, sow a full crop, if not already done. *Cauliflowers*, raise the hand-glasses, and loosen the soil between the plants; after which give them a good soaking with manure water. *Celeriac*, continue to prick out young plants. To be always kept well supplied with water, rapid and continual growth being a most essential point in its cultivation if it be required large. *Cucumbers*, the young plants intended for the ridges to be stopped, and repotted if they require it. Sprinkle the plants in the frame early in the afternoon, and close them; water more liberally round the sides of the frame where the heat of the day dries the soil. *Dwarf Kidney Beans*, sow on a warm border. *Gherkins*, sow. *Herbs*, transplant Camomile, Mint for distilling, and other herbs where a large supply is wanted. *Lettuce*, repeat the sowings of all sorts. Thin out and transplant those advancing as occasion may require. *Potatoes*, hoe between the early crops as soon as they are above ground. Where circumstances have hitherto prevented the getting in of the main crop it should be done at the earliest opportunity. *Scarlet Runners*, sow in a warm situation. *Sea-kale*, keep the crowns well soiled over for late cutting. *Turnips*, sow a good breadth.

FLOWER GARDEN.

If evergreen shoots must be planted take care to preserve every fibre. To be taken up with large balls of earth, and the holes to be dug larger than the balls will fit into: a good soaking of water to be given, and to be firmly staked, to prevent the injurious effects of wind waving. Finish, if not already done, the pruning of those summer Roses that were left unpruned for the purpose of retarding their bloom. If green fly appears it can be effectually removed by syringing them with weak tobacco-water, and the Rose caterpillar by picking them off with the hand. Make a sowing of perennial flower-seeds in the reserve garden.

FRUIT GARDEN.

Look to blossom protection on the walls. On the first appearance of green fly on the Peach and Nectarine trees syringe them with tobacco-water two or three evenings successively; if done properly it will stop their destructive progress for the season. The mining grub, so destructive to the Apricot and Plum, may be detected: when the leaves are folded up they are easily crushed between the finger and thumb. If strong plants of the Elton Strawberry are lifted now, and planted behind a north wall, they will produce a crop in August and September, and will keep up a succession along with the Alpines to the latest period. Where Vines have shot sufficiently to distinguish the fruit-bearing shoots let all superfluous ones be immediately removed. Examine grafts frequently, removing on every occasion the wild shoots.

STOVE.

The plants here are now in vigorous growth, and, therefore, they must be assisted by a lively bottom heat, a brisk-growing temperature, with plenty of moisture and air, and weak manure water to such plants as require it. The *Ixoras* now expanding their bloom-buds to be set close to the glass where they can have plenty of air to colour the blooms properly. Start a fresh lot of *Gesneras*, *Gloxinias*, and *Achimenes*.

GREENHOUSE AND CONSERVATORY.

Look well to the plants in the borders of the conservatory, and if dry, give them a good soaking of weak liquid manure that will percolate through the whole mass of soil. The plants in these structures to be carefully examined in the forenoon of bright days to see that none of them are suffering for want of water; for with bright sunshine, accompanied with drying

winds, they are very apt to flag for want of water, more especially any specimens that may be rather potbound. Ventilation to be so given as to avoid, while parching winds prevail, allowing currents to blow through the houses. Forward *Calceolarias* and *Cinerarias*, and keep them clear of insects. Water *Camellias* freely with weak liquid manure, but do not let the water hang about their roots. Keep the shifted ones close and warm. *Heaths* and New Holland plants to have an abundance of air, and to be watered very carefully. Shift *Pelargoniums* wanted to flower in autumn, and propagate desirable sorts. Keep all climbers, whether in pots or otherwise, regularly trained.

PITS AND FRAMES.

Continue to pot off rooted cuttings as soon as they are in a fit state for the purpose. The most forward portion of the stock to be removed to a cold pit. See that they do not suffer for want of shading and water during bright sunshine. Attend to the stopping of the shoots to induce a robust bushy growth. Shut up early in the afternoon, having previously on sunny afternoons given the plants and the walls of the pit a good syringing with soft water. Cover up close at night, and uncover early in the morning, giving plenty of air during fine days.

W. KEANE.

DOINGS OF THE LAST WEEK.

DIGGED, turned, and pulverised garden ground, flower-beds, and borders, being glad to turn down the surface dry and warm, and bring up the cold and wet to the influence of sun and air. Sowed more garden Beans, Peas, Carrots, and a little Beet for early supply, preferring to sow again in a fortnight or three weeks, so that little may be tempted to run to seed, which it is apt to do when sown early as often recommended; a run root being hard and stringy instead of crisp, juicy, and sweet. Pricked off Tomatoes and Capsicums; planted last of Potatoes. Watered with warm water some fresh-planted young fruit trees, and transplanted old ones, and threw a little water with the syringe over their heads in warm, sunny days. Hoed the ground slightly among Strawberries; removed the rough of any litter between the rows; lifted some young plants that had been planted 4 inches or 5 inches apart on a border in September, and potted them to get assistance under glass for a last in-door crop, and plunged the pots in a bed of leaves just slightly warm; but with no covering of any kind. This will secure the pots being crammed with roots before they are placed in a cool house. Removed plants gathered from, and planted at once in a border, in rows 2 feet apart and 15 inches from plant to plant. Placed more pots of British Queen and Prince of Wales in the houses, and fresh arranged, tied up the fruit, and thinned the clusters of those there, to be forwarded or retarded as occasion demands. I have no glass frame at liberty, but at this season would have made a slight hotbed of leaves, and from the middle to the end of the month would have filled it with young plants taken off the border as above referred to, placing them firmly in stiffish garden soil, about 9 inches or 12 inches apart. Such a plan does very well at this season, but it would entail disappointment if tried in the early spring months. For early forcing the pots should be filled with roots in September, and receive all the sun possible afterwards. In sunny seasons we have also had Strawberries three weeks earlier than in the open air, by placing a frame over them, and covering the ground between the plants with tiles and slates, and shutting up pretty early in the afternoon. To prevent red spider the back of the frame or even a portion of the slates may be daubed with sulphur and water paint. Top-dressed Cucumber-roots in pit with a little very rotten, well-aired leaf mould; the plants producing plentifully and now overtaking and passing these in the dung-bed frame, but from which we, nevertheless, obtained our earliest fruit. Pegged out and tied up Melon plants. Thinned Grapes, keeping the scissors clean, and regulated and tied in shoots of Peach-house. Trees on open wall, protected with old sashes last winter, seem all right, have hardly a Peach bloom elsewhere, and trees gone very much. Have placed an orchard-house almost finished over the trees in bloom, and filled the front with maiden and older trees of Peaches, Nectarines, Apricots, Plums, Cherries, Gooseberries, and Currants in pots, and expect a great amount of pleasure as well as fruit in another year. The state of the trees on the wall that had merely the protection of old sashes, contrasted with the wrecks and ruins elsewhere, assures me plainly what glass alone fairly managed can accomplish. Even

a little heat in extreme cases need not be such a great affair as some make it. The hot-water tradesmen, with all their good qualities, have done much to frighten amateurs with their huge boilers, huge expense, and a lot of pretended secrets about the work, which intelligent men do not like.

In the conservatory, took a number of Azaleas finished blooming into a glass-fronted verandah, where they could be kept close, shaded when necessary, and sprinkled overhead to encourage fresh growth. Filled up the empty space with bedding plants in boxes needing a little help. Moved Camellias done flowering to the vinery to give them a help to make their young wood. Moved Pelargoniums and Cinerarias to supply their place, arranging the house afresh, placing flowering plants chiefly on the north side, and all growing plants to the south, and the Pelargoniums, &c., being moved from the late vinery. The Fuchsias from the other early houses were placed there, and after standing a few days the larger were shifted into 12-inch and 14-inch pots, and the younger ones will get a little more pot room as time will allow. The Vines in the late-house must be tied up ere long, as, though the shoots are kept at the front of the house, and all possible air given there, and the Vines never syringed, the buds are now breaking and from 1 inch to 2 inches in length. The earth-pits are now the safety-valve for getting room. Lobelias, Verbenas, and Ageratums finding their way there—some planted in lumps of spring-struck cuttings; some singly according to kinds and room, but all thick so that they will not hurt each other before planting time. The Calceolarias, &c., under the calico are looking even better than a few under glass. Most of our stock of Verbenas were planted out in the slight hotbed spoken of the other week, and are looking nicely, and will, no doubt, lift nicely. Sowed also such annuals broadcast, under protection for a time, as Love-lies-bleeding, Prince's Feather, Chrysanthemum tricolor, Convolvulus minor. Such a plan enables us to plant when the ground is warm and well-aired, and the plants, if moved in little patches, hardly ever feel the moving; and last year such things as Prince's Feather, when sown at once in the borders, hardly ever got above a few inches in height, even when it did grow instead of making a massive row from 3 feet to 4 feet in height.

—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

FLOWER-GARDEN PLANS (Notice, Dublin).—Every week we have to repeat that we never plant plans for any one; we only criticise the planting proposed by our correspondents. No planting will make your series of parallelogram-beds look well. The advertisements may all be cut away from our Numbers. The binder knows how to manage it. (B. S. A.).—The first part of our reply to the preceding applies to you. We cannot plant for you. The weeds and earth of your garden thrown into your cesspool will absorb the liquid, and if you add a little sulphate of lime (gypsum or plaster of Paris), that will fix the ammonia. Burnt clay, of course, would be better than common earth, but burnt clay, you say, you cannot procure.

PEAR LEAVES PARTIALLY DECAYED (D. B. E.).—Either the buds were injured by the winter's severe frost, or the roots are rather defective from some cause. If the first be the origin of the evil, it will extend no further. If it extends further—that is, if more leaves become decayed—lift the tree carefully out of the pot, remove some of the old soil from about the roots without disturbing them, add a little fresh soil, give good drainage, and repot. We have not lost sight of the price list, but there are difficulties in the way of obtaining reliable information.

PEACH BLOSSOM FALLING IN ORCHARD-HOUSE (J. B. G.).—We think it very probable that the exposure of the pots to the intense frost, which you say they had to endure unsheltered, may have so injured the roots as to deprive the tree of the means of supplying the sap required for the blossoms. The frost may even have injured the blossom-buds. If the red spider has robbed the trees of the sap they should have stored up for next year's development, the blossoms always fall unproductive.

OUR ILLUSTRATIONS (W. I.).—We are quite aware that these would look even better than they do if we could afford to print on better paper, and we shall do so if the paper makers allow us to benefit by the reduction of the paper duty. It is quite true that to use a better paper would cost about 7s. 6d. per 500 copies; but if twenty times that number are required weekly, and as there are fifty-two weeks in the year, that would amount to rather more than you suggest.

BOTANY (J. Forster).—Polyandria is the ninth order in the class Monœcia. There are only ten orders in it altogether.

FUMIGATING PEACH TREES (Rev. C. D.).—They may be fumigated with tobacco smoke without injury though in bloom. You had better write to Messrs. Baker, Phœnicians, Beaufort Street, King's Road, Chelsea, for information about the Bretonne crows. They import them.

VARIOGATED PLANTS (Jerry).—All that you enumerate are very good, and most of them superior to those we recommended; but in our answers to correspondents there are considerations founded on statements in their letters which prevent those who do not see their statements being entitled to form a judgment upon our answers.

CINERARIA MARITIMA CUTTINGS AND SEEDLINGS, &c. (W. W.).—In answer to repeated inquiries, Mr. Fish, at page 362, Vol. XXX., of *THE COTTAGE GARDENER*, gave in his opinion the best mode of propagating the above from cuttings, and if a better mode can be found for that purpose he will be glad to hear of it. It is no part of his duty to inquire who possesses a stock of this or of anything else, but merely to do his best to meet their wants as these wants are made known. He prefers plants so raised for edgings or lines, but he has no objection to make against seedlings. If these can be had 2 inches or 3 inches high before the middle of May, and the points are picked out with the point of a sharp penknife, they will make nice edging plants. Few plants are easier managed, and few grow more vigorously out of doors after the middle or end of June. After this season, therefore, our correspondent may please himself whether he keeps a stock from cuttings or from seeds. Unless in a rough piece of ground, we consider that the flower-stalks, and flowers too, add little beauty to the plant. For edgings or rows we consider them altogether out of place, and, therefore, we nip off all that appear; but we will find no fault if our correspondent prefers the flower-stems even to the foliage. We see no reason why the *Petunia Comtesse d'Ellesmere* should not succeed in any garden in Yorkshire. If raised from seed, it is just possible that there may be many shades of colour. Some varieties of *Petunia* come very true, and others do not. Other things being equal, seedlings are more hardy and continuous in growing and flowering than plants raised from cuttings. We have had many a good bunch of Grapes under circumstances similar to yours. Instead of a crop next season, less than half a crop would be advisable, if the lengthened well-doing of the Vines is to be considered.

LIME WATER FOR STRAWBERRY PLANTS (E. J. E.).—This application for the destruction of slugs, &c., which lodge about the plants should be clear. Like all other lime water for gardening purposes, it is made by putting a peck of lime freshly slaked into forty gallons of water, stirring it well, and letting it remain until quite clear, which will be in about half an hour. Use the clear liquor. Ten gallons will be enough for watering your single row 60 yards long.

VARIOUS (Flora).—We do not know a white *Heliotrope*. The strong-growing *Triomphe de Liege*, has a large light lilac flower, but it cannot be called white. The hardier *Honeysuckles*, *Clematises*, and climbing *Roses*, will do admirably in your iron verandah facing south-west. The *Lemon* and *Citron* will grow slowly on the back wall of a conservatory, but neither will bloom or fruit unless they get a good portion of sun; and this they could not have if your *Camellias* shade the wall.

FLOWER-GARDEN PLAN (Q. E. D.).—A basket-bed in the centre of your pretty flower garden, in front of your house, would be most objectionable; but a dial on a highly finished pedestal set on a deep bold plinth would be in harmony with that style of flower garden. Then your *Verbenas* in Q, R, S, T. You are quite right about M, N, O, P, but no edgings there. H and I are for edgings, and a row in the centre of each of *Perilla* to where they measure 6 feet across; then two rows of *Perilla* 18 inches apart up to the end of each; and any other plants will agree with *Perilla* if you have a good variegated edging. C, C, and C F, must be bright scarlet; G, D, and E, bright yellow; K and L light colours, as *lilac Nierembergia* or a clear white; A, A, and B, ought to have broad white edgings; the rest as you say. W must be your ribbon-border with three rows only. *Cerastium* next the walk, blue *Lobelia speciosa* next row, and your best variegated *Geranium* at the back; but if you are short of them, any plain-leaved dwarf scarlet kind will do for a shift. Dwarf *Dahlias* might occupy 10 feet of the broadest ends of H and I, and do better than so much *Perilla*, and with a row of *Scarlet Geraniums* round the *Dahlias*, with an edging in front. It is a pretty plan altogether, and should not have *Stocks* and *Asters* till they are nearly coming into bloom. All your beds beyond M, N, O, P, might have permanent edgings of hardy plants, the width to be according to the size of the beds; and all such in all places ought to be taken up yearly in April and reset—that looks well, and is a great economy of pot plants and adds to their effect. But let us hear at the end of the season how it all looks, and what people said about it, and what changes you or your friends propose for another year: we like such gossip.

VINES NOT FRUITFUL (T. T. T.).—By merely stating that your *Black Hamburg* bears well, whilst the *Sweetwater* and the *Muscadine* on either side of it do not bear well, you give us too few data to enable us to form an opinion as to the cause. Are the Vines weak? Then a dressing of superphosphate of lime and rich manure waterings might effect a remedy. Are the Vines making very strong rampant wood? Then, perhaps, the roots are too deep; and all the sun and air and extra heat must be given in the autumn to ripen and harden the wood. Could you manage to let a good gardener see them?

EVERGREEN FOR BACK WALL OF GREENHOUSE (A Manchester Subscriber).—We should decidedly prefer the *Magnolia fuscata* to an *Arbutus*. A box 18 inches square and as much deep would grow a good-sized plant. We have seen the *Acacia armata* covering such a wall with fine effect. It is always green, and in spring its flowers clothe it with a dazzling gold colour, but it is liable to red spider if not well supplied with atmospheric moisture.

BRITISH WILD FLOWERS (G. W. Ray, and others).—The work will be completed with the least possible delay; but as many of the rarer species are difficult to obtain, we cannot at present give a decided answer. Every drawing will be from living specimens.

HEATED GLASS CASE (B. R., Liverpool).—Yours is not a Waltonian Case, and the gentleman at New York whose interesting letter you had read lately in these pages, will now be able to tell the tin men of New York, that those of Liverpool are just as ignorant of its construction as they are. He, the said gentleman, spent £15 trying to get up a Waltonian Case in New York from the very same drawings in Mr. Shirley Hibberd's book, and failed as you have done. I st of all, and last May, he ordered a Waltonian without the case from Mr. West, and all the advice we can give you, is to go and do likewise.—D. B.

YELLOW POLYANTHUSES.—Mr. Beaton requests us acknowledge the safe arrival of these.

SHELTERS (*An Old Wellwisher*).—Haythorn's small-meshed hexagonal netting, and Shuw's tiffany, are the most effective shelters we have tried for protecting the blossom of wall fruit.

STAG BEETLE (*E. F. Lee*).—It is called by entomologists *Lucanus cervus*. During the day they live in hollow trees or other decayed wood, taking flight at dusk. The females are sluggish, and not so numerous as the males, who fight for their possession. The larva is found in the trunks of decayed willows and oaks, and remains untransformed for several years—Rosel says six years. It is believed to be the *Cossus*, eaten as a delicacy by the Romans. When the larva is full grown, it forms a cocoon of the wood-dust which it has gnawed down with its powerful mandibles. It remains some time in the pupa state, but its life as a perfect insect is brief.

VARIEGATED FERN (*D. L.*).—It is only *Asplenium adiantum nigrum*. The marking is caused by insects, and, of course, will not be permanent.

PLANTING FLOWER-BEDS (*A Constant Subscriber*).—We see nothing to alter in your beds or system, except that a principle is broken by the way you put the Verbenas in beds 2 and 3. That is not their position by rule of right; towards the centre, where 4, 5, and 6 stand, is the place for Verbenas; 4 with *Calceolarias*; and 5, 6, with *Scarlet Geraniums*, would ruin an acre for effect, being in the very centre. Whether you can depend on *Gazania* for beds, depends on what part of the world your garden is in. What *Rose* to put on a wall with south aspect, depends on where the south aspect is; but as there are only two or three yellow *Roses* for a wall anywhere, try *Cloth of Gold*, and *Isabella Grey*.

SEEDLINGS OF MARTYNA FRAGRANS (*O.*).—These, just up, require the treatment of seedling mignonette in pots with respect to water—that is, to be sparing of it. They require the very same treatment as seedling balsams with respect to air and heat, and that amounts to abundance of air and very little heat. And as to soil, young *Martynia* plants require exactly the same kind of soil, and the same sized pot, as you would give to a little cutting of *Tom Thumb* just rooted and being divided from the root—and that means small pots and any odds and ends you can scrape together round the potting-bench.

PRUNING IVY (*J. S.*).—Never "clip," but cut the shoots in with the knife, unless you intend to remove all the leaves and young shoots. The latter is a good plan, for although the stems look miserably bare for some time, yet the foliage speedily recovers them closely and brightly. Whether you prune or clip, *now* is the best time.

SEEDLING CINERARIAS (*Queen*).—They are only suitable for borders. They are not novel or superior either in colour or form.

PLANTS, &c., FOR WALTONIAN CASE (*Cavendish*).—To heat a miniature greenhouse, such as you describe, you would require a small copper boiler and two inch-pipes. The water to be heated with at least three jets of gas; but you must so place the jets of gas that no effluvia from it enters your greenhouse. The plants that you name will answer your purpose, excepting the French *Marigold* and the *Brachycome*. Instead of them, procure *Calandrinia umbellata*, *Fenzlia dianthoides*, *Sabbatia campestris*, and *Spraguea umbellata*. The *Primulas* will not flower till next spring, and the *Cyclamens* will be three years before they flower. The piece of a plant you sent is, we believe, some species of creeping *Phlox*; but, from such a small dried bit, it is almost impossible to be certain what it is. When it flowers send a branch with blooms upon it, in a small box, packed first in tissue paper, and then surrounded with damp, not wet, moss, and we can then tell you its name.

NAMES OF FERNS (*A. M. R.*).—1, *Gymnogramma chrysophylla* apparently; 2, *G. peruviana*; *Callipteris prolifera*; 4, *Asplenium premarosum*; 5, *A. Fabianum*; 6, apparently a stunted form of *A. contiguum*; 7, *Lastræa*, probably decomposita, but the specimen is too fragmentary; 8, *Adiantum cuneatum*; 9, *Lastræa globella*.

NAMES OF PLANTS (*S. H. L., Camberwell*).—1 and 2, *Heaths* without flowers; 1, appears to be *Erica vestita*; 3, *Epacris impressa*, or some garden variety of it; 4, a garden variety of *Correa*, apparently *C. bicolor*; 5, *Coronilla glauca*. You may cut down the *Epacris* after flowering, but it is hardly to be recommended with the other three. Cannot you bend the stems downwards, and so induce young shoots from below?

FLOWER SHOWS FOR 1861.

MAY 18th. CRYSTAL PALACE. (Plants, Cut Flowers, and Fruit). Sec., W. Houghton.

JUNE 5th and 6th. ROYAL HORTICULTURAL SOCIETY. (Plants and Fruit). *Garden Superintendent*, G. Eyles.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

MAY 21st, 22nd, and 23rd. CHESTERFIELD AND SCARSDALE. *Hon. Sec.*, Mr. Thos. P. Wood, jun., Boythorpe House, near Chesterfield. Entries close May 1st.

MAY 22nd and 23rd. BEVERLEY. *Hon. Sec.*, H. Adams. Entries close May 4th.

JUNE 4th, 5th, and 6th. BATH AND WEST OF ENGLAND. *Steward*, S. Pitman, Esq. Entries close May 4th.

JUNE 19th, 20th, and 21st. COALBROOKDALE. Secs., J. B. Chune, and Henry Boycroft, Coalbrookdale.

JUNE 21st. ESSEX. Sec., W. R. Emson, Slough House, Halstead, Essex.

JUNE 28th. DREIFIELD. Sec., Mr. R. Davison. Entries close June 22nd.

JUNE 28th and 29th. TAUNTON. Sec., Mr. Charles Ballance. Entries close June 14th.

JULY 3rd, 4th, and 5th. BLACKPOOL AND WEST LANCASHIRE. Sec., Mr. E. Fowler, jun., Market Street, Blackpool. Entries close June 30th.

AUGUST 26th, 27th, 28th, and 29th. CRYSTAL PALACE SUMMER SHOW. Sec., W. Houghton.

SEPTEMBER 3rd. POCKLINGTON (Yorkshire). Sec., Mr. Thomas Grant. Entries close August 26th.

DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. Sec., Mr. J. B. Lythall, 14, Temple Street. Entries close November 1st.

DECEMBER 11th, 12th, 13th, and 14th. CRYSTAL PALACE WINTER SHOW. Sec., W. Houghton.

N.B.—Secretaries will oblige us by sending early copies of their lists.

EARLY CHICKENS FOR THE LONDON MARKET.

It may be, when last week we spoke of the almost incredible sums sent into Sussex for the small chickens of which we were writing, that some of our readers thought of a common American saying, "If I were a Duck, I would locate at that same puddle myself." The science of profitable poultry-keeping will never be practised or understood till the supply of the early London market enters into the calculation.

Now, an extraordinary value must be caused by scarcity, and that again will be the result of a failure of the breed, or the anticipation of a natural season. The fatted chickens may be put under the last head, and the profitable period will be from the 1st of April to the 1st of June.

The first requirement is, they must be young, and by that term we do not mean comparatively young. That is a very elastic term in a poultry-yard some persist in calling all pullets that are under the year old, after which they fall into the position of hens. Pullets are very valuable in the market; but they must be pullets indeed—those that have never laid.

To speak plainer, we will say pullets fatted for sale in March and April should be hatched in November or December. Much will depend on the season and the weather; a fowl is older at the end of four hot months than it is after five if they have been cold, and ten days' warm weather at the end of four or five months will turn the pullet to the hen; she is then worthless for the table. A popular error is that there is some great secret in preparing fowls for the market, and that none but the initiated can do so profitably. There cannot be a greater mistake; all that is necessary is to fast them before killing, to pick them clean, and to send them up fresh. There was difficulty formerly in doing so. No dependance could be placed in coaches, as they were full at times, and the cost of carriage was very heavy; ordinary road waggons were too slow; but now there is no place that is not in communication with a rail, even if it be not on the line.

Young poultry will pay if sent to the London market. We are quite prepared to hear some say they have tried it and have been disappointed; but we are sure they did not follow strictly our advice given in THE COTTAGE GARDENER. There is always a good sale in April and May, and we might add the end of March. In those months there is more or less partial dearth of young poultry, while the demand is always large. There is no doubt of a sale at remunerating prices. It has been sometimes objected that those we quote every week are imaginary, and that none can ever realise them. We can assure our readers we do not quote those that are made by the choicest qualities; but, seeing such are bred, fed, killed, and packed by those whose livelihood it is to send them, and who have had many years' experience, we should not think it fair to do so.

Within these four weeks many thousands of fowls have made from 12s. to 14s. the couple. These are in every respect perfect. To realise this price they must be sent in the most saleable form. We cannot expect amateurs who have only a few dozens in the year to compete with those who have as many every day; but if we can induce them to send up a few chickens, we shall teach them a profitable mode of disposing of surplus or faulty stock, and we shall help to increase the supply which is at present totally inadequate to the demand. We do not advise them to send after May; the market is then better supplied, the weather is hot, and we will not always promise them a sale; but now, and during the next month, there is always a demand. They need not be very fat; there is no occasion to cram, but it is well to shut them up for a week or ten days, and to feed them well on ground oats mixed with milk three or four times per

day, giving each time only as much as they will eat clean. They must be fed early in the morning, and all this involves but little trouble or expense. The chickens must be good-sized; and many who have tried to sell in London and have failed may attribute it to the fact, they sent them too small. They should weigh at least 2½ lbs. each, and if more so much the better. We are very anxious this should be tried, because, anomalous as it may appear, the supply of poultry at the Leadenhall Market has decreased since it has been more generally kept than it was formerly. To pack them they should be put in a basket, the layers being divided with stiff straw. The chickens should be tight, spare space being filled with the straw, because if they have room to shake about they lose the stiffness, which is the proof of their being recently killed—a valuable thing to the purchaser; and they also lose shape and colour—both good properties.

POULTRY FOR A CONFINED SPACE.

I HAVE a piece of enclosed ground, 12 feet wide and 20 feet long, as well as a piece of grass 12 feet wide and 8 feet long, for a poultry run. The poultry-house is 3 feet 4 inches wide, 10 feet long, and 7 feet at the back and 9 feet at the front high, situate in a side entrance. There is a tunnel from the house to the run underneath the garden door, so as not to interfere with ingress or egress of the inmates of the house. Will you inform me how many fowls I shall be enabled to keep without overcrowding?—T. H.

[You would have helped us to answer your question if you had told us what breed of fowls you keep. If Cochins, Spanish, or Brahmas, you may easily keep two cocks and eight hens without overstocking. The number is not regulated so much by the size of the bird as by its aptitude or otherwise for living in a small space. Next to these would be Spangled Hamburgs,

or Game; but the latter are apt to be very quarrelsome when shut up. If, however, you do not care to keep so many birds, you may have in such a place as you describe a cock and six hens in very great comfort, and consequently in very good condition.]

COD LIVER OIL AS A REMEDY FOR PIGEON DECLINE.

HAVING seen in a recent Number of THE COTTAGE GARDENER a letter from "COLUMBARIAN," requesting you to give a longer account of Pigeons at the different shows, I hope, as a constant subscriber, I may add my voice to his. There are, I have no doubt, several who take your publication chiefly for what they can hear on that subject; and it would be a great assistance to young fanciers if you could induce some of your correspondents to write weekly for that purpose.

I do not know whether any of your readers have tried the effect of cod liver oil on Pigeons that are "going light," or wasting away from consumption or other causes. As I had never heard of its being used, I determined to try it, and certainly it exceeded my most sanguine expectations. During last autumn I had eleven birds ill from that disease; and several of them so bad that they could neither fly nor eat, and, consequently, were as thin as it was possible to be; but I only lost one, and that was too far gone when I began the oil. I mix it with barleymeal and wheat flour, and give as much as I can get down three or four times a-day, and can safely say that if used in time, very few birds will be lost.

I also noticed a letter from Mr. Brent on turned-crowned Pigeons, and cannot understand why he does not include Turbits, as fanciers look upon the crown almost as a property, and it certainly makes the head appear much shorter than if it were without the crown.—W. H. C. OATES, *Besthorpe, Newark.*

THE RABBIT (LEPUS CUNICULUS): ITS HISTORY, VARIETIES, AND MANAGEMENT.

(Continued from page 36.)

THE CHINESE RABBIT.

THIS very handsome and interesting species is also known under the names of Polish Rabbit, Russian Warren Rabbit, and more generally as the Himalayan; but how they derive this name I am at a loss to know, although they are spoken of by Mr. Woolf in the "Proceedings of the Zoological Society" as the Himalayan; also in the Zoological Gardens they are labelled Himalayan or Black-nosed Rabbit.

M. Didieus speaks of them as natives of China, carried into Russia by the nobles to augment the number of fur animals which constitute the chief revenue of many of their lands. From Russia this variety passed into Poland, and from thence into Germany, from whence it was imported into France.

They have red eyes, like the Angora Rabbits. Their fur is whiter, finer, and more lustrous than the common white Rabbit; and the extremities—that is, the nose, ears, feet, and tail are black or a rich brown; the darker this colouring is the more perfect they are considered, but they do not arrive at this perfection till about six months old. When young the extremities are of a light mouse colour.

This race is very hardy, and often used to people warrens and open burrows. It is bred principally for its fur, which is very valuable, and is sold from 1s. 6d. each to 2s. 6d. It is the best imitation of ermine, for which the Russian nobles often sold it. It is now called "mock ermine."

This Rabbit is now very largely cultivated on the Continent. It is useful and interesting for the amateur to breed, being very pretty, hardy, and prolific, the skins valuable, and the body large enough to be useful for the table.—R. S. S.

(To be continued.)

PROFITABLE POULTRY KEEPING.—No. 2.

(Continued from page 51.)

My first attempt at poultry-keeping on system was commenced with hens of every and of no breed. I got them as I could, from the common barndoor fowl to the stately Spanish and aristocratic Game. But even this had its advantages, enabling me to form a just estimate of their peculiar good qualities, and to discard the comparatively worthless. For all purposes, however, I prefer the Dorking, and the speckled of that breed for choice, whether for the table or their eggs. With me they answered best, and were in more general demand by the poultry dealers.

But the subject of hens and their breeds is of too great importance to be cursorily glanced at. A future communication must be devoted to this part of our subject.

In discharge of the promise made in my last, I now give the readers of the "Poultry Chronicle" the results of poultry-keeping for profit.

The following account is drawn by striking the average of three years for 100 hens, having a run of about two acres of grass land, and about a quarter of an acre of yard.

Dr.	EXPENDITURE.	Cr.	RECEIPTS.
	£ s. d.		£ s. d.
To food.....	31 16 0	By return from 100 hens,	
To rent, management, loss,		at 18s. 9d. a head	93 15 0
and interest.....	16 12 0		
By profit—Balance	45 7 0		
	£93 15 0		£93 15 0

Or about 90 per cent.

Now, supposing the stock kept to reach the number of 500 hens, if the poultry keeper's wife charged her own services at £52 a-year, and those of a strong active girl at £30, including her maintenance—£82 per annum, it will be seen how handsome a return would even then be derived from this branch of rural economy.

And now for an analysis of the items of the above account. I will premise that the above profits can readily be extended, if fattening fowls were the chief aim. For instance: If my reader will refer to the Cr. side, he will find that I give the return of each hen at 18s. 9d. Thus, a hen will lay on an average

120 eggs at 1d. 10s. 0d.

Besides hatching a brood, of which she will rear, on an average, 7 chickens, at 1s. 3d. 8 9

18 9

I found the expense of rearing chickens up to the age of from ten to twelve weeks did not much exceed 1d. per head per week, and having a good grass run. Hence, if a couple of chickens cost 1s. 8d. to rear for sale, and then brought 2s. 6d., the profit would be 50 per cent.; but if they were kept until they were five months old, costing 2s., they were then worth 4s. 6d. or 5s. each, thus giving the extraordinary profit of 125 or 150 per cent.

To obtain these prices, however, it is but right to say, that the young poultry must be ready for market when game is out of season, and just at Christmas; for though game comes in in August, it is not until the Partridge falls that the poultry keeper finds the demand lessen and prices drop.

And this is well, even as "all is well" which is ordered by our Divine Father. The tired hens need rest, and it is the season Nature enjoins for them, for they have done their work well and patiently; and if their master will continue to feed them abundantly, and not neglect them during their time of non-productiveness, they will yield him a golden harvest at Christmas. I know no prettier sight than a hen with her young brood, and does not our Saviour himself use them as a simile towards the close of His holy life?—LEIGHTON.

(To be continued.)

PARROTS DEPRIVED OF WATER.

IN your Journal I am much surprised at your reply to the lady correspondent, "A. Z," at the ignorance of her adviser to

keep her Parrot without water. The general belief is that water is injurious to them, and I know it is in my neighbourhood, where several are kept; and with regard to myself, I have had one for more than ten years, and have never given it any water, and it is very healthy. I have even offered it water but it will not take it. We feed it simply with soaked bread, with the water moderately squeezed out of it, and hempsed.—W. T.

[It may be that Parrots, fed upon soaked bread, "with the water only moderately squeezed out of it," may find enough moisture to preserve them from thirst; but we are quite sure that no Parrot or Cockatoo ought to be kept without a tin of water attached to his cage to drink from if he required. Moreover, we are equally sure that the opportunity of taking a daily bath should be offered him. In a state of nature those birds have such opportunities, and no animal is judiciously managed that has not a supply of everything as nearly resembling as possible the supply afforded by Nature in the animal's native place. The best specimens of the Parrot and Cockatoo we have known were well supplied with water, both for drinking and bathing.]

BREEDING CANARIES.

A FEW weeks back I put three Canaries up for breeding, two hens to one cock. Last Thursday or Friday one of the hens began to build, and finished her nest by Monday morning. On Tuesday I was rather surprised to find she had filled up the nest with cotton wool. I gave her more building materials, as I thought she might, perhaps, build again on the top of the old nest. She began on Wednesday, and made it about three quarters of an inch deep, and has not made it any larger at present (Friday night). Do you think there is any chance of their breeding? and what was the reason of her filling up the nest? The other hen has not begun to build—in fact, the cock drives her about the cage, and she drives the other hen. What am I to do in case like this? The cage is 34 inches wide, 20 inches broad, and 37 inches in height. I suppose that is large enough for three birds. The cock does not sing. He has never been mated before, but the hen has.—T. M. N.

[In placing two hens with a cock it is always advisable to put them together first, and let them become well acquainted before they are put up to breed with the cock. As the two hens now quarrel it will be safest to part them, although the cage would otherwise have been large enough. The nest which is built too full in the middle may have part pulled out, and the remainder made smooth by means of a heated iron ball or stone; the eggs can then be replaced, and all extra building material removed from the cage.—B. P. B.]

CANARIES' FEET DISEASED.

ALLOW me to offer some advice to "R. S. V.," page 17, on the subject of a diseased Canary's feet.

If the perches, floors, and even the wirework of the cage itself are not kept well scraped, and scrubbed with scalding water and soap, they are liable to become infested with a minute inflammation—causing insects so small as almost to defy a magnifying power. These titillating animalcules form preserves, especially on uncleaned perches, in neighbourhood with the bird's feet and legs; and they eventually disperse themselves in myriads over the body of the poor perch, which may then be compared, parasitically, to those attacks on the human frame, the mere mention of which is sufficient to cause blessings on the Duke of Argyle, and to make us take every preventive caution to defend our feathered favourites from its ravages. For this purpose scrape over the convex surfaces of the perches every morning, as well as the floor-board when it is withdrawn from the cage, to release the debris, previous to the board being fresh sanded. Before it is returned insert the scraper, and clean away any residuum from off the bottom of the cage, well working the implement over its surface; when any living thing there will be made to feel very uncomfortable, and consequently emigrate.

About every six weeks during the summer, and twice or so during the winter, fasten down the windows, turn the birds out into a room, lock the door and put the key in your pocket; and take the cages and perches, and cause them to be well scrubbed—wirework and all—with soap and scalding water, and when they are dry, return the birds into them; or, rather, they will go in of themselves if they are kept without food half-an-hour or so beforehand.

Eschew sugar, sweet cake, hemp, rape, and moss seeds. Adhere to canary seed, plantain, and minute crusts of bread, now and then, as cereal food; groundsel, chickweed, shepherd's purse, or water cress, as never-failing supplies of green food; and apples, pears, and strawberries, in season, as pomological diets. When the birds are moulting, give modicums of chopped boiled egg.

Give the birds to drink pure fresh water every morning, and a wired-over cold-water bath, hooked on opposite the meanwhile-opened door of the cage, frequently, even during the coldest weather.

"Dick," a Canary, we have had in vigorous health during eight years, takes good care to remind us of remissions on our part anent the bath by imaginary dippings and plungings, shakings and bawlings; and when the glass is down below zero, his amphibious propensities are sufficient to make one shudder.

Do not keep the birds too hot during winter, though below 50° or 45° the temperature should not go; also give plenty of light and air. We, for a long time, bred Canaries in quantities, and have kept them all our lives, and never found any difficulty in warding off disease, and preserving them in health under the above dietary tables and attendance to cleanliness.

Our "Dick" is a great traveller, and makes himself most popular on the road. I remember once, in particular, at the Durston station, where we were kept waiting an unconscionable time for a train to take us on to Plymouth, "Dick" was placed in his travelling cage upon the apex of a heap of luggage, and his powerful song attracted every traveller to the spot. It was as good as broiled bones for supper, on board ship: every one soon became chatty friends, and *ennui* knew us not. Even the porters could not withstand the fascination; and it was really relishing to see the big fellows—on whom an ichthyosaurus might, one would have fancied, only have been able to make an impression—powerfully attracted to the spot, to enjoy the twitterings of "Dick."—UPWARDS AND ONWARDS.

THE CANARY AND THE BRITISH FINCHES. (Continued from page 35.)

9.—THE CHAFFINCH (*Fringilla Cælebs*).

German, Der Bachfinck.

French, Le Pinçon.

THE common Finch or Chaffinch, known also by the names of Twink, Shelly, Chaffy, Boldie, and Beech Finch, and in Scotland as Shilfa, has been surnamed *Fringilla Cælebs*, or Bachelor, because of the separation of the sexes in winter in those countries where they migrate. The females usually leave first, and return last; which, however, is also the case with some other migratory birds in this country. I believe the migrations of the Chaffinch are only partial, most of them remain with us the whole winter.

In plumage the males are certainly handsome birds, though the colours are somewhat softened and subdued. The head is dark bluish-grey, the back brown, the wings black, the base of the secondary wing-feathers and the ends of the larger covert-feathers being white, and thus forming bars on the wings; the breast is a dull pinkish-red, the belly inclining to white, the rump greenish, the tail dark, having white marks on the inner webs of some of the outer feathers. The plumage of the females is much duller, the head, breast, and upper parts being of a greyish-olive brown; the hen is also rather smaller than the cock.

The young ones all resemble the mother; but the males may be distinguished by the blacker colour of the wings, and their having clearer and more white; nor do they attain the full colour of the male till after the second moult. In autumn the beak of the cock is pale, but, as the spring advances, it changes to a deep blue shade; nor is his general plumage so bright in autumn and early winter as it is in spring, when winter and time have worn off the duller edges of the feathers, and he appears in his nuptial dress.

The Chaffinch breeds early. The nest is placed in the fork of a tree or bush, frequently in a fruit tree, and is a very neat and beautiful construction—smooth and rounded in the form of a ball, depressed at the top, firmly felted together with webs and wool, covered externally with moss and lichen, and often so much resembling the bough on which it is situated, as to be discerned with difficulty. Inwardly it is lined with thistle down, hair and a few feathers; the eggs, from three to six in number, are of a dull dirty white, spotted and streaked with coffee brown. Incubation lasts about a fortnight.

The food of the Chaffinch consists principally of insects, as caterpillars, grubs, moths, earwigs, &c., on which they rear their young; and in the destruction of which they do an immense amount of good, and therefore should be protected as much as possible. In winter, when their natural food is scarce, they are driven by hunger to feed on seeds; these they gather from the ground, and not from the plant as most other birds occasionally do. In hard weather they may be seen searching the horse-dung along the road for undigested grain, or collected in the farmyard in search of hay seeds, or scattered corn; and considering the great good they do all the summer, they well deserve a tride in winter.

The Chaffinch rarely eats green food; but in spring, when insects are scarce, they sometimes annoy the gardener by pulling up his young radishes, or cabbage and caulidower plants, and eating off the white parts of the root, occasionally also attacking the early peas in the same manner: it is, therefore, necessary to protect these from their depredations by means of nets, or strings of feathers, and not to kill the poor hungry birds that, all the summer through, are so active in destroying those insects which, if unchecked, would devour our fruit and convert our gardens into wildernesses. The Chaffinch is one of the few birds that eat that destructive insect the gooseberry caterpillar.

Young Chaffinches, if intended to be reared by hand, should be taken early from the nest, as soon as the tail-feathers begin to show, or they will soon fly, and then they are sullen and do not open their mouths readily to be fed. They should be fed on a paste made of sopped bread, hard boiled egg, and maw seed, or the bread may be soaked with milk; but it must never be given in the least sour. As the old birds rear their young exclusively on insects, principally on caterpillars, it is obvious that in artificial feeding some such food as egg or milk must be used to insure their well-being. Rapeseed is, in my opinion, decidedly injurious. Numbers of young Chaffinches raised on it die at the first moult; and I have noticed my old birds rejected that seed while anything else was to be had. The old birds may in confinement be fed on canary seed, oats, (shelled oats are best), bread, and occasionally, but sparingly, a little hempseed by way of treat; or during the moult a few mealworms, ants' eggs, or earwigs, will be relished and often found beneficial.

Of all our native Finches the Chaffinch is the most delightful songster. His short, but sharp, clear, thrilling note is the harbinger of spring. His joyous lay always brings to my mind the blossom of the sweet-scented hawthorn, the busy hum of the bee, the opening of the buds and early flowers, when Nature in all her freshness is awakening from the dreary sleep of winter, and when the fruit trees and orchards are clothed in snowy bloom, and the white petals are being scattered in showers by the gentle breezes. Who then but must admire the Chaffinch when, perched on a spray, he gives utterance to his pent-up love in a joyous burst every few seconds, jerked forth with an energy which tells of his sincerity—his loud call *twink, twink*; or with erected crest and waving tail, he utters his plaintive purring note, *churree*, to his mate, who is perhaps busy forming their nest, and his still louder and angry warning *pink, pink*, if he fears his brood will be discovered? The song of the Chaffinch is composed of three cadences, delivered with that earnestness which is so attractive to the ear of the fancier; and on which account it is so highly prized, not only in this country, but also on the Continent. The terminal notes or last cadence is that which attracts most notice, and as it varies in different individuals, it usually gives the name to the song and value to the bird. Mr. Hipkins, who so well describes the song of our birds, observes, "The English fanciers have several strains of birds thus denominated in former times, the choeweydo, the whitfado, the kissmedear, &c.; but the choeweydo is considered the best song, one of the best limbs being, *ching, ching, ching, ull, ull, ull, choeweydo*; the last note the oftener repeated the better, technically termed "heavy in the month." This applies to all the notes, the principal difference being the termination or finish of each strain; the birds vary the notes in each limb, but terminate with whitfado, kissmedear or choeweydo, according to the strain to which they belong." He also remarks, "The English fanciers will sometimes travel twenty miles to peg a bird, and I have seen good blind pegging birds sold from £2 to £3 each."

It is a curious fact well authenticated by fanciers that the birds which sing the choeweydo, or ehnekwidder song best are caught in Essex, therefore called the sweet-song Essex Chaffinch, while the other strains are caught in the adjoining counties, and other parts of England.—B. P. BRENT.

BEE-HIVES AND THEIR APPURTENANCES.

(Continued from page 53.)

WOODEN-TOPPED STRAW HIVES are favourites, and used principally for any early prime swarm set aside as a swarmer, affording superior facility for removing the surplus store compared to the dome-shaped, which are more used for seconds and late prime swarms not expected to yield anything the first season. These are cylindrical in form, the straw bands began on hoops, are 14 inches wide and 7 inches deep. Round the topmost band of straw one or two outer or second bands are continued, which serve as a rest for a flat circular ring of inch-wood—inner circumference 14 inches, outer 18 inches; on this is placed the usual 1½-inch bars with slides secured with three-quarter-inch brass screws, therefore moveable at pleasure; this top is fastened to the hive by stout screws inserted through the under side of the outer straw bands. Any inequality between the straw and wood has to be made up with putty or Portland cement: little crevices about the windows in the same manner. In case the latter should start from its place, I usually slip a little cord over the top and bottom of it, which, lying between the straw bands, is not much noticeable.

SLOPED WOODEN-TOPPED STRAW HIVES, I have latterly adopted as an improvement on the last, taking the hint from my roof bees, which always select a part with a good bevel. They are in every respect similar to the above, with the exception of the straw bands being kept thinner in front, thickest behind, and gradually tapered on each side between the maximum and minimum, the one 9 inches and the other 7 inches, including the hoop. I think the bees thrive fully better, and come through the winter in finer condition in this hive, ventilation being doubtless promoted by the bevel. Little slips of wood tacked on prevent the super from sliding.

DEPRIVING-HIVES.—For depriving-hives, the most suitable material is wood. The shape, is unquestionably the nearest approach to a sphere—an octagon. This and double swarms were two points on which that good old bee-keeper Thorley was perfectly sound, writing nearly 120 years ago: therefore the

STEWARTON OCTAGON-HIVES have a prominent place in my apiary, being, I feel confident, the cheapest and best ready-made hives for practical bee-keeping to be had. I order mine direct from Stewarton, where I find, from the demand, they can be purchased in quantity, with better workmanship, at a price nearly one-third less than local tradesmen will undertake to supply them at. To those of your readers who have them, they require no description; to those who do not yet possess them, my advice is, Obtain them as soon as possible, and they will by-and-by speak for themselves. Should these lines catch the eye of any of their makers, I would suggest the propriety of sending along with each set concise printed instructions as to their management. I am led to make the remark from observing, in a recent Number, a querist asking if they were wrought collaterally, and also meeting a clerical friend who complained of his want of success. The first question elicited the cause—How were they peopled and protected? A first swarm, no cover to be sure, that would quite spoil their appearance. Expect honey from a *single* swarm, in a set of Stewarton-boxes the *first* season—half-inch wood unprotected! Why, the only wonder was, that, despite all the attractions of such a terrestrial paradise as the manse garden, they had not at once made a precipitate flight back to the old-established stock from which they had seeded. Such of your readers as occasionally indulge in amateur hive-making would find the advantage of ordering along with their boxes a supply of bars and slides, forming the tops of these hives, long lengths preferable—say 7 feet for the former, 7½ feet for the latter. Bars 1½ inch for stocks, and 1½ inch for supers. They can be easily cut into any length, and fitted, instead of the clumsy adapters and crown-boards, to all the old hives of the apiary when again to be used, or the new ones about to be constructed. Odd ends of slides, the upper edge run off with a plane, are very useful to work shutters, moveable entrances, &c., in. I like to procure at the same time several additional octagon honey-boxes, both the fourteen-inch for these, and the twelve-inch size; they make cheap and tasteful supers for all the other flat-topped hives.

The beauty of the Stewarton-supers, that so attracted the lingering admiration of "UPWARDS AND ONWARDS" when in Glasgow, was not, as he supposed, indebted to the dark-coloured product of the heather then in bloom, which, on the contrary, would have quite spoiled their surpassing purity. They are

generally to market before it comes into flower. His surprise at the superiority of the octagons surely carried him too far when he awards the palm as a bee country to our poor bleak Scotland, over the rich pastures and flowery meadows of his own England. The contents of these supers are drawn chiefly from one little plant—the white clover. The light sandy soil of a large portion of Ayrshire is favourable to its natural production, even were the farmers so neglectful of their own interests as not to sow it liberally when laying down their pasture. The bee-keepers reap their share of the benefit by the painstaking and skilful manipulation of double prime swarms in a good hive while it remains in bloom; indeed, in many instances, moving them inland bit by bit, as the flower fades, to later localities, till the supers are completed; and then, and not till then, as a reward for their industry, are transported to the moors to rifle the purple heather of its dark juice for their own benefit during the winter. Such, having little local value, being sought after principally by the tourist. Thyme honey is only to be had in quantity in some districts on the border.

SQUARE WOODEN HIVES retain a place with me for two reasons only—the first, that to the amateur doretailing *four* boards neatly together is much less of a puzzle than *eight*; secondly, they afford space for a larger window for observation. The bulk of these hives is 14 inches square within, by 7 inches deep, to work with the large-sized octagon supers. They are fitted with eight bars, six of them 1½ inch wide, the remaining two 1½ inch, are placed one at each end. These every bee-keeper knows are devoted exclusively to honey, and are, therefore, better than the broad size. I have also tried, and still have, nine bars 1½ inch wide in some fourteen-inch straw hives, keeping them closer at the centre, so as to leave as wide end-openings as possible. The bars are notched out at each end the breadth of the back and front, so as to allow the slides to work flush thereon, project barely an inch behind (the corners nipped off for appearance sake). The object of this is to assist raising the bars when the three-quarter-inch screws by which they are fixed have been drawn. They are constructed of well-seasoned yellow pine front and back inch-dressed, ends three-quarter. The inner sides, unless very clean, had better first be dressed, and then run over with a toothling plane. Should that implement not be at hand, a good substitute is a bit of perforated zinc, the cut edge drawn along with the grain of the wood till it be well roughened: this materially assists the ascent of the heavy-laden forager. One window of *thick* glass 11 inches by 4½ inches placed behind, when bedded in the putty to prevent its starting, fix with four small sprigs; the putty above the glass then laid on. The shutters of wood 12 inches by 5½ inches dressed to a quarter of an inch thick; a check in the front edge top and bottom to work in pieces reversed slides as already described for straw hives. If I used a second window it would be in front, although more in the way there, it is of use by throwing the light through the hive at first, and showing the commencement of breeding in the spring: whereas an end window is nothing but a useless disfigurement to some hives, exposing to view only the end-sealed honeycomb. I have also wrought with considerable success, a size 13 inches between the ends, 12 inches front to back, and 9 inches deep, fitted with eight bars 1½ inch wide, in every other respect same as the above, with a proportionately large window and shutter, both fitted with end-handles for lifting, 4½ inches long by 1 inch deep, and three-quarters out, and entrances moveable, as will afterwards be described, 5 inches by three-eighths of an inch. These, as well as all my hives, are, of course, duly protected from the weather, when standing singly outside, by a good fresh straw thatch or some other cover.—

A RENFREWSHIRE BEE-KEEPER.

(To be continued.)

HOW I BECAME AN OXFORDSHIRE BEE-KEEPER.

SOME eleven years ago, a kind neighbour, when flitting from these parts, presented us with a hive of bees, and where to place them I could not tell, for from the only corner where I could domicile the insects I had grubbed up the protective end of an old yew hedge, anticipating the erection there of an orchard-house; but owing to the umbrage taken by a neighbour, and a flaw which the lawyers found against the rector felling two oak trees to repair his house upon his own ground, which had been the custom far beyond the memory of the oldest inhabitant, an

injunction in Chancery caused the timber to lay and rot, my orchard-house to remain "the baseless fabric of a vision," and to cost the rector between £200 and £300.

Now, having lived with the rector nearly all my life, it grieved me much to think that I should so unwittingly have been the cause of his losing so much money; but where to place the bees, that was the question. It was of no use to stand still and call upon Jupiter for assistance so I at once ran up a wattle-work fence, 7 feet high, on the site of the removed hedge, to be annually strengthened by driving in stout poles, planted Irish ivy against it, and, behold, from that time an evergreen shelter was established. Had I erected an orchard-house there, later experience has proved that it must many a time have stood the risk of being blown away; or, at least been partly destroyed over and over again by tiles and chimney-pots.

"Why, Brotherton, I told you to place the hive in the cloth, or otherwise rest it upon a piece of board the full size of its bottom." "Ah! I didn't use the cloth, for I thought that piece of board would do very well at this time o' night." "Thought! I suppose you calculated on the bees remaining as dormant and glued to their bed as you would be yourself? But look! it is not so, you have scattered them along the road, and numbers are crawling about you. There now, quick march! pray go and bring the stand as quickly as possible."

Poor old Brotherton! that was easier said than done. He has in his time been fighting for his country in different parts of the world, and is awarded a small pension, with one of his legs from the hip downwards twisted, and fixed at nearly right angles with the other, so that neither his pace nor the rough journey to the bees was much to be wondered at.

It was at Michaelmas time the hive thus arrived to us, considerably weakened by the distribution of the bees. The remainder lived through the winter, and became strong and populous during the next season, without offering to swarm. In the following year they threw a strong swarm and a cast, and three common stock-hives remained our bee capital. I was quite a novice, and did not understand supering, and as to destroying the poor bees for the sake of taking their honey, I could not do it; I had become attached to them, and they had become attached to me, and my attention was becoming excited by Mr. Payne's writings in *THE COTTAGE GARDENER*. Withal, the hives, after the manner of the old-fashioned common hives, did not behave through the next winter satisfactorily. The queen died in the swarm first hived, and the bees forsook it and the honey; and the cast put into the other hive kept me continually dancing attendance with an elder-wood trough feeder. The original hive remained strong and healthy, and from the quantity of dead bees and fighting observed in February, I became aware afterwards that all the bees that could do so had joined it from the queenless hive.

In fact, I was getting quite bewildered, and I determined in future to adopt Mr. Payne's cottage-hive system. He was written to, and kindly sent me a supply of his flat-topped hives, supers, and a bee dress, and I set to work with fresh vigour. My original hive threw me a swarm only the third year, and the cast stock gave a late swarm, so I had now established two new hives, and four in all. The early swarm in the new hive worked us some honey, and I cut a hole also in the top of the original hive, which gave a full super—great events!

Two years more passed, and I had established a rank and file of the Suffolk hives, and notwithstanding the supering, they would swarm; and in the winter time I found that deaths, reverses, continual attendance, and anxieties attached to them, even till my state of mind was becoming worse than my first.

Then followed experiments hopeful and hopeless; the jokes of my friends, and the metal (in two senses of the word) I was put upon, served to urge me on considerably, and to fill a lumber-room with I do not know what of bee apparatus, a description of which, and all that it led to, it would be useless to cumber these pages with. One plan, however, began to decide for me its superiority and I have that original hive now in a flourishing condition, after doing duty for six years. I exhibited a glass, and a straw super of honey worked from it placed on a new representative-hive *pro forma*, at the Oxford Horticultural Show, on the 23rd of June, 1857. It was mentioned in No. 458 of *THE COTTAGE GARDENER*. Certainly it gained its full share of attention, and when I was absent from its presence I placed Brotherton conspicuous, to answer what questions he could, and he told me a Frenchman was eager to purchase the whole thing as it stood "at any price;" but it was

not for sale: my object entirely was for the poorer sort to see it and to take the hint; and you know from letters I have sent for your perusal occasionally, the judgment expressed on the quality of my honey, and the glass mentioned above was pronounced, at Messrs. Fortnum and Mason's, one of the best samples that ever entered their establishment. I also gained credit there for my plan of packing honey for carriage. So having already been "smiled upon," and, furthermore, considering six years' trial a sufficient recommendation, I will describe the plan as being most applicable to myself, in the hopes that it may also prove beneficial to others.

The aspect of my apiary is very good—*south-east, and gaining the early morning sun*, and from the situation of some beech trees, it becomes shaded during the sunshine of summer by twelve o'clock, and remains so during the afternoon through the agency of the wattle-work fence. The passages in italics must be taken into consideration by all apiarists in embryo, and allow me to add, they are well worthy of acceptance to all bee-keepers whatever. The fence adjoins a corner of the house. My nearest hive is 8 feet distant from the latter (the garden front upon which my espereone vines are trained), and all the hives are placed in a line, 4 feet from each other, measuring from each pedestal, and 5 feet from the fence; this interval, and that flanking the house, are gravel walks. The ground in front of the hives is occupied as flower-border, and that beyond is cultivated garden. All operations are performed at the backs of the hives, and no person's walk, or shrubs and vegetables are allowed to grow so high within a certain distance as to interfere with the starting-point of flight, or return of the bees, and nothing immediately beneath and around the hives is allowed to grow; but the soil there is frequently stirred during summer and winter time with a Dutch hoe, for the disturbance of ants, &c., and to keep the soil dry and warm. A few loads of "log wood," stout limbs from barked oak trees, are annually purchased here to be sawn and riven up to heat the oven. Out

Fig. 1.

Fig. 2.

1. Pedestal, 6 inches diameter, 3 feet 10 in.
2. Block-board, 1 foot 6 inches diameter, 2 inches thick, with three screw holes.

of six-inch diameter stems culled from these I form my pedestals, taking care to choose a limb with a branch grown out at its side thus (see drawing), and to saw it off at the fork slightly slanting, through the centre of the bulge *AA*, where a broader and tougher surface can be got to screw on the block-board (see drawing). This I form out of a piece of gnarled ash, 2 inches thick, and 1 foot 6 inches in diameter. It is screwed firmly on to the top of the pedestal, its lip pointing away in the direction that the branch took, with three three-and-a-half-inch-long screws placed triangularly, 3 inches apart, and having their heads sunk into sockets in the block half-an-inch deep, so that in case of after-warps a plane may be worked over its surface to keep it perfectly level. The pedestals thus formed measure 3 feet 3 inches in length; the least split in them is well puttied up, and they are painted a dark ivy green colour, excepting the surface and the parts that are to become inserted in the ground—1 foot 6 inches deep at least. The soil that is dug from the holes to admit them, I take care to return it all again by degrees, and well ram it around

the stocks with not too large a rammer, for no post was ever properly secured in a hurry; and unless all the soil is returned that was taken out, I would not willingly hang my gate or place my bee-hive upon it.—UPWARDS AND ONWARDS.
(To be continued.)

VARIETIES.

MONROE'S PATENT EGG-BEATER.—We know of no minor invention more really useful than this. Every cook knows the time, and the arm-aching, and disappointment attending upon the beating or whisking of eggs, &c. Now, all this is prevented by Mr. Monroe's invention. It fixes to a table or dresser, and by turning the handle of the machine, a rapid and double agitation is given to any batter or liquid mixture on which it is employed; and in a few minutes works them to a degree of lightness, very far surpassing that which can be produced by the ordinary hand-whisk.

SEWING MACHINES.—The introduction of the sewing machine has established a new era in the manufacture of all articles requiring the use of the needle. The rapidity with which the invention has been perfected and applied to general use, is the most remarkable fact in the modern appliances of machinery. The structure of the machine has been so finely adjusted, that now every species of sewing can be performed with the utmost accuracy and neatness.

Six years ago, there were but 2500 machines in the country, whilst at the present time there are in operation nearly 100,000. The following statement gives the progress made in this department of manufacture from the year 1853 to 1859:—

In 1853—Sewing machines made	2,500
1854 " " " "	5,000
1855 " " " "	3,600
1856 " " " "	7,400
1857 " " " "	12,785
1858 " " " "	17,659
1859 " " " "	48,000
Total during 7 years	96,944

The manufacture of sewing machines is becoming an important branch of industry. One firm alone (Messrs. Wheeler and Wilson), employ upwards of 400 hands, with a monthly pay roll of 40,000 dols.; their works covering an area of nearly four acres in extent, and giving employment to a capital of 400,000 dols. Estimating their average selling price at 85 dols. (their value ranging from 50 dols. to 150 dols.), we have 8,240,340 dols. as the total amount for machines sold during the last seven years, one-half of the sales having been transacted within the present year. To show the importance of the export trade, we may take the following as a criterion of its extent.

Export of sewing machines from the port of New York for the week ending December 12, 1859:—

	No.	Value.
To Liverpool	3	375 dols.
To Glasgow	cases 129	12,408
To Constantinople	boxes 6	315
		13,098

We subjoin a statement of the several purposes to which the machine is applied, with the time occupied in making each article as compared with handwork.

	By machine.	By hand.
	Hrs. Mins.	Hrs. Mins.
Gentlemen's shirts	1 5	13 51
Frock coats	2 38	16 35
Satin vests	1 14	7 19
Linen vests	0 48	5 14
Cloth pants	0 51	5 10
Summer pants	0 33	2 50
Silk dress	1 13	10 22
Merino dress	1 4	8 27
Calico dress	0 37	6 37

Ordinarily at the rate of a yard a minute.

In addition to these purposes, this invention is applied to the manufacture of collars, cloaks, hats, caps, gloves, umbrellas, boots and shoes, harness, upholstery, &c. On striking an average from the above table, we find that the amount of work done by the machine is in the ratio of 7 to 1 as compared with handwork. Estimating the number of machines now at work

in this country at the safe computation of 90,000, and supposing that of that number two-thirds, or 60,000, are in constant operation, we shall have an amount of work performed equivalent to the production of 360,000 hands; or, to put the matter in another light, it would appear (deducting 60,000 for those employed on the machines) that the introduction of the sewing machine has displaced 30,000 sewing hands. It is manifest, however, that the latter consequence has not been realised; for it is a fact that hand-sewing labour is now both as scarce and as dear as it was seven years ago. The invention, therefore, has been no detriment to the operative class; but it has proved instrumental in developing the various branches of trade to which it is applied, by a large saving both of time and cost in manufacture. Its bearing on the health of a numerous class of our working population is most beneficial; the unhealthy posture, the closely packed work-rooms, and the painfully close application which belong to hand-sewing being exchanged for an easy and pleasant employment. This is one of the many boons conferred by the great ameliorator of human toil—machinery. All honour to the inventor of the sewing machine!—(New York Herald.)

HOME-MADE VINEGAR.—Every housekeeper with a yard or garden, on which the sun shines the greater portion of the day in summer, should make her own vinegar; it is so good, so cheaply made, and above all so pure and wholesome. Put 1½ lb. of brown sugar to 1 gallon of water; boil it as long as any scum rises, which should be taken off as fast as it comes to the surface. When milkwarm, or, say, at a temperature of 60° or 65°, dip a slice of toast in yeast, and put it in the liquid; which should then be put into a pan, or tub, to work for one day, then be put into a cask, which should be painted outside to keep it from being injured by the weather. The cask should then be placed on bricks to keep it from the ground, in a sunny place; a piece of coarse muslin should be nailed over the bung-hole, and a tile placed on it to keep out the rain. If this simple brewing is done in March or early in April, the vinegar is fit for use in October following. It is good for pickling and all family uses.

OUR LETTER BOX.

FOWLS DYING (A Constant Reader).—The bird sent was too decomposed to be of any service in forming an opinion. The symptoms, "a swollen crop, purple comb, and lingering five hours," are those of poison; but we wish to speak guardedly, as poisoning is too often held to include malice, whereas there are many things that fowls may pick up, and which may be fatal. A yard is sometimes depopulated by corn that has been arsenically dressed for sowing being thrown to the fowls; or water is poisoned by the remains of boot-top or copper cleansing being thrown down where the fowls frequent. Remove the fowls from the spot, and purge them thoroughly with castor oil, a table-spoonful every day for three days. Feed on oatmeal mixed with strong beer.

BOOK ON POULTRY (H. E. G. S.).—The best coloured portraits of fowls are in Johnson and Winkfield's "Poultry Book," a copy of which costs about £1; it also contains abundance of practical matter. Mrs. Blair's "If a Fowl," is price 7s. 6d., and is an excellent practical directory; so is Mr. Baily's "Fowl," price 2s., and so is our own "Poultry Book for the Many," price 6d. They may all be had at our office, or be sent free by post on the receipt of postage stamps to their respective values, and two extra for the dearest books, one extra for the last named for postage.

LUMP IN THE THROAT OF YOUNG PIGEONS (Leghorn Hunt).—When the lump of pus in the Pigeon's throat can be got at, remove it with a wooden instrument, and touch the place with caustic. As to the cause, I suspect it is often caused by mice wetting on the food. Drinking from metal vessels has been also supposed to induce the disease. As a preventive I would advise the Pigeons to have free access to salt and green food.—B. P. BRENT.

BREEDING CANARIES, MULES, &c. (A Regular Subscriber).—You will do well to take the hen Canary from the cock, with which she fights, or shut her in the small division of the cage till the cock has become master of the place, and she will then, most likely, beat her into submission. It would be a pity to separate the Goldfinch and his mate that agree so well. I do not think the loss of the toes will prevent the hen Canary breeding. See that the perches are of good size and firm. Probably she will not lay till her foot is well. A Linnet of the preceding year will breed very well with a Canary; but it is generally considered that a two-year-old bird is better to breed from.—B. P. B.

WEASELS (J. P.).—Keep the chickens shut up in a place without holes large enough for a Weasel to enter. Set a steel rat-trap baited with a piece of very fresh meat.

LONDON MARKETS.—APRIL 22.

POULTRY.

We shall have little to note in the way of change in this market till we have warmer weather. The increase is more in the trade than the supply.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 61.5° and 39.4° respectively. The greatest heat, 81°, occurred on the 4th, in 1833; and the lowest cold, 20°, on the 2nd in 1855. During the period 143 days were fine, and on 95 rain fell.

FLOWER SHOWS IN TOWNS FOR THE WORKING CLASSES.

ONG ago we began collecting examples of "gardening under difficulties;" and when we received, a few days since, a schedule of prizes to be awarded to members of the working classes exclusively in the London parish of Bloomsbury, we contemplated it as an addition to our store for use at some future period. At first it struck us it must be a joke—some satire upon our metropolitan shows, and that 'Bloomsbury' was selected as an apt name for such a quiz.

Our readers, however, will be no less surprised than at first we were, to find that it is sober earnest. There not only is to be such a Working-class Flower Show in Bloomsbury next June, but there was one last year, and a successful one, too. Let us, in the first place, detail the entire prize list, and the rules which will regulate the Exhibition. They are as follows:—

"BLOOMSBURY FLOWER SHOW.

"AN EXHIBITION OF PLANTS BELONGING TO THE WORKING CLASSES OF THE ABOVE PARISH WILL BE HELD (D.V.), ON WEDNESDAY, JUNE 19TH, 1861, IN THE NATIONAL SCHOOL-ROOM, BURY STREET.

"The following Prizes are offered for competition:—

"1. Prizes for Adults.

"1. Persons living in the little Coram Street district—viz., Little Coram Street, Abbey Place, Chapel Place, Russell Place, Coram Place, Marchmont Place, Tavistock Mews, Colonnade, Little Guilford Street.

First Prize. Second Prize. Third Prize. Fourth Prize.

For ANY PLANTS.....	10 0	7 6	5 0	2 6

"The following are the rules to be observed:—

"1. Exhibitors must bring their names and addresses, with the name and number of the Plants they intend to exhibit, to the Parochial Vestry, between the hours of 10 and 12, on any morning of the week after April 22nd, and no person will be allowed to compete who has not given in his name on or before Saturday, May 4th.

"2. The Plants so registered must remain in the parish, and under the care of the Exhibitor, until the time of the Exhibition.

"3. Different members of a family are eligible to compete for the Prizes.

"4. The Fourth Prize in each class will be given to Plants not in bloom.

"5. The Plants are to be brought to the Schoolroom on the day of Exhibition, before 10 in the morning.

"6. No Gardener or Flower Dealer to be allowed to compete for the Prizes.

"7. Admission to Exhibitors free, to non-Exhibitors 6d. before 5 P.M., after that time 1d.

"N.B.—Exhibitors are advised to procure Plants which may be expected to be in bloom by the day of the Show.

"WALTER H. BOSANQUET, Esq., 5, Torrington Place, has kindly consented to give further information to intending Exhibitors, and is also willing to register Plants within the time specified above, every evening after 7.

"EMILIUS BAYLEY, Rector."

This Schedule was accompanied by a letter, from which, though marked "private," we shall venture to publish some extracts.

"On the chance of your taking an interest in such a thing, and of your deeming it worthy of favourable notice in your widely-read Journal, I enclose a programme of an intended Flower Show for the poor inhabitants of the parish of St. George's, Bloomsbury. If you do not consider it worthy of favourable notice, I hope you will not condemn it. The same kind of show was tried last year on a very small scale in the same parish. The Rev. S. H. Parkes, one of the Curates, and a most energetic man, started a flower show, or rather an exhibition of plants, confined to the inhabitants of one of the narrowest and most thickly populated streets in the parish. The only rule which had to be kept by exhibitors was that each must have had his plant in his possession for three weeks. Any kind of plant was allowed to be exhibited, and it was not necessary that they should be in blossom. It was felt that at the first attempt it would not do to be too strict.

"The result was entire success, and the number of plants exhibited by no means limited. The Russell Square gardener and an amateur acted as Judges on the occasion, and awarded the prizes, which were given away on the evening of the day of exhibition, by Mr. Bayley, the Rector.

"One of the great objects of the Show was to induce the really poor to take an interest in plants, which may add so much to the cheerfulness of their dwellings. Great difficulty was

No. 657.—VOL. XXVI., OLD SERIES.

felt in awarding the prizes in consequence of the very large variety of plants exhibited, some of which were utterly unfitted to a London atmosphere. When a repetition of the experiment on a much larger scale was suggested this year, the difficulty which had been experienced was mentioned, and in consequence the competition this year is limited to Geraniums, Fuchsias, and Annuals. I feel that it is of no use encouraging the poor to cultivate plants which cannot repay them for their trouble, and which must cause them disappointment. By the rules you will see that each Exhibitor must on the day of the Show have had his plants in his possession rather less than seven weeks, and it is trusted that the great object in view—viz., the finding out, not who can buy the best plant, but who can take the best care of a plant, will be attained.

"At the same time the classes are so arranged that the inhabitants of the narrowest streets are not brought into competition with those who live in situations more favourable to the growth of plants.

"I think that the cultivation of plants is a very great civiliser, and I hope great good may come from the Show. I am in hopes that you may think the scheme worthy of favourable notice in an early Number.

"I say as well mention that although the programme says that only the fourth prize in each class will be given to plants out of blossom, there will be many more given in reality, because the people in the classes for whom the Show is meant, being without the means of procuring or taking care of many plants, could not insure having any in bloom at the particular time appointed for the Show, and much disappointment might be caused. Intending Exhibitors, it is known, regardless of the day fixed, would probably go and buy plants already in full glory or nearly so."

Now, if ever a step was taken in a right direction for benefiting the working classes, this is one. Nothing tends to raise a man, woman, or child above the temptations of sensual pleasures so effectually as a bright, cheerful, decorated home: and no home is so bright, cheerful, and winningly decorated, as that where flowers are fostered.

We have traversed the length and breadth of most parts of the British islands, and we record, as the result of our observations, that *life is longest, and the working classes are the most moral and well-to-do where a fondness for gardening prevails.*

This result of our experience is not extracted from rural districts only, for it is sustained by inquiries among the masters in the manufacturing districts. In Sheffield, Birmingham, Manchester, Coventry, Spitalfields, and elsewhere, those who cultivate florists' flowers, and those who love to search for wild flowers as members of the many botanical clubs that are so numerous among the weaving operatives, include scarcely any but men who are the most skilful and the most exemplary.

We think in all towns, whether manufacturing or commercial, the example set in Bloomsbury might be followed most advantageously; and in Bloomsbury we think they might have exhibitions for other flowers than those included in the present schedule—such flowers as the Auricula, Polyanthus, Pink, Antirrhinum, Pomponé Chrysanthemum, Cineraria, and Hyacinths, all of which may be successfully cultivated in pots and in city dwellings. Such shows would require to be held at three seasons of the year; thus the interest and care would be sustained throughout the twelvemonth. We think, also, that every exhibitor should pay a very small entrance-fee, to be carried to the funds of the exhibition.

One anecdote, and we have done.

We knew a village blacksmith, sober, industrious, and exemplary. Years passed, and we then found him an idle, sottish, ragged vagabond. We inquired of his brother how this ruinous change was caused, and the reply was this:—"When poor Fanny died, he married his present wife; and she never had home comfortable for him. Fanny kept things tidy—loved flowers, and had some for his button-hole on a Sunday—but she (his present wife), is no good, always gossiping, and pulled up poor Fanny's Geraniums to spite him."

CLIMBERS FOR A TRELLIS ON A NORTH-EAST ASPECT.

B. W. would be much obliged by the name or names of the handsomest and largest-flowered perennial Clematis, or other showy climber suited for a trellis, with north-east aspect. It must be perfectly hardy, as the situation is cold and exposed. Soil fine yellow loam. Locality near Ipswich. B. W. recollects many years ago seeing a splendid flower of the Clematis family and bought it, being assured it was quite hardy, but the first winter killed it; but B. W. must say it was placed in the immediate suburbs of London, where, from want of vigour, plants do not bear cold so well. Now would this answer (if you know the plant I refer to), for a climber in my small greenhouse where there is never a fire or any other covering but the glass to keep out the frost?

[For such a position out of doors we would use Clematis cœrulea, C. Hendersonii, C. flammula, C. florida bicolor; and such Roses as ruga and multiflora, and the hardier Noisettes. For the house grow Clematis Sibboldii, cœrulea grandiflora, Lonicera japonica, and Passiflora cœrulea, covering the latter with a mat or cloth in winter, as you use no fire heat.]

KEW GARDENS.

OF all the improvements in gardening for the last thirty years, none are so telling on the eyes which have seen the work of other days as the winter management of house plants, and the beauty and freshness of the plants themselves at the period of general potting in the spring. Kew is up to the highest mark in the records of this progress; yet the houses are not half large enough for the wintering of the vast collection.

When the new conservatories are finished and filled, as they will be before another winter, the gardeners at Kew may make larger specimens of their best plants; but they can hardly make them look more healthy than they are at present. The winter has hardly touched them, comparatively speaking. The annual deaths and casualties are not so heavy this spring as they have been in former seasons, yet the numbers of kinds of plants that are out there is not nearly matched in any establishment in the British dominions, nor anything like it. The situation is not at all favourable for holding out against frost, the water being constantly within a few inches of the surface in some parts of the grounds, and the whole surface not much above the level of the tide. It is the poor, hungry sand, and the gravelly bottom which save the exotic collections of Kew from severe seasons such as this last winter. Plants do not grow rank in such soil, and they ripen and harden before the winter, and if they are hardy anywhere it is in such soils.

I could see nothing to speak of among all their evergreens. No Rhododendron is hurt. The Sikkim Rhododendrons out in the lowest part of the grounds, but shaded and sheltered by some of the finest timber trees on the establishment, are safe as ponticums; and visitors to Kew at present must needs be told that the list of killed and wounded is made up by the writer from official documents, for neither they nor their informant could make the discovery in going over the grounds.

But it was the spring decoration in-doors that people from the country wanted me so much to report for years past; to whom I used to reply, "What can you expect that way in a botanic garden where nobody knows where to find room for the next plant he pots? Everything must be so crammed there that flowers are out of the question altogether." Indeed, such was my impression. I often wished myself to see their Acacias in flower; but then it occurred to me, that they may think I want only to criticise a certain deficiency. But this spring I had a very good excuse in the late frost, and so I went and found everything quite different from what I expected. Bulbs of all sorts forced for show as for a private conservatory; all sorts of forcing Geraniums, from Alba multiflora to Blanchefleur and Mrs. Johnson, which was new to me; Musk, Cherry Pie, and Violets, free as among country cottagers; Heaths, Eperisies, and Acacias as coming natural; magnificent Ferns, stove plants, and foliaged fineries all on the exhibition style of look and growth; Orchids done on the Kingston model at last, and no soul or body allowed now to go in and out in all weathers, which was the ruin of many plants besides the Orchids.

It is all very well and very wise of the Government to get young people down to Kew, and add to the poetry of their eyes and under-

standings; but it was neither wise nor well done from the beginning, to have allowed stove and other rare plants to be injured by a constant flow of visitors in and out the whole winter, giving an occasion to that enemy to have two strings to his crossbow. All that is altered now, and "private" on one of these doors does not mean you and I to have a private chat there, but that the place must be kept private for the safety of most valuable plants in winter and till their season's growth is done and ripened, then you can see them and welcome—and they will soon be worth seeing and something more. But my mission was about flowers, and began in the Heath-house, where, also, all the best Epacris were in bloom; where *Rhododendron javanicum* is now in full bloom, and many other fine things, from *Aphelaxis* to *Cytisus*, *Correas*, *Pultenaea*, and others, the host of March decoration. The Heaths in bloom, and the easiest Heaths for us and ours to have for March blooming were *mutabilis*, *pubescens* and *pubescens minor*, *persoluta*, *andromediflora*, *flava*, *triumphans*, *perspicua nana*, *colorans*, *urecolata*, *scabruscula*, *gracilis*, *viride* (vestita sort), *vernix*, *ovata*, *ramentacea*, just going out; *brunoides*, *lycopodioides*. Also, *Boronias* of sorts, and *microphylla* in fine bloom; *Polygalas*, ditto; *Chorozema varia*, and others; *Daviesia umbellata*; *Brachysema latifolia* and some others, and all in bloom gay as a show day.

No. 10, the grand show-house, and the best greenhouse in all England, where none is better managed, or is more gay in March and April, if not the whole year round. I was wholly surprised, as they say in Suffolk. All the best *Hyaecinth*s, early Tulips, and *Narcissuses*, which were recently before your eyes from Highgate and Pine Apple Place Nurseries, have been forced for this house. Everything that has a sweet leaf to it; all *Geraniums* that will force, and as many *Cinerarias* as would fill the tables of the Floral Committee with beauty, and their heads with dismay, are got up early for this decoration, and thus a man from London, with *THE JOURNAL OF HORTICULTURE* in one hand, and a guide-book for Kew in the other, may enjoy more flowers of an afternoon at this season of the year, than the Laird of Tullivolen, or the Duchess of Kippelbringham herself can do down in the provinces, to say nothing of all the *Cyclamens*, *Primula denticulata*, the varieties of *P. chinensis*, with *Dielytras*, *Deutzias*, *Daphne rubras*, *Lilacs* large as life, *Saxifraga ligulata*, with rhubarb-like sized leaves; *Solanum capicastrum*, in bushes with berries golden as the apples of *Hesperides*; *Rhododendron formosum* and *ciliatum*, *Ferugiums*, *Camellias*, *Roses*, and *Mignonette*. Then, in lesser numbers, are *Arctotis grandiflora*, blooming like a *Gazania pavonia* the year round—this is the source of an endless race of Hybrid Perpetual bloomers for in-doors and out; *Zieria macrophylla*, also a perpetual bloomer such as it is. Then most splendid tree Ferns, and the finest specimens of *Gleichenias* anywhere, in the rudest health, and in the largest tubs that must fall to their share. And then the *Acacias*—a sight when they are all in bloom, but this is only a small selection of them. *Acacia cecastrifolia* is one of the very best with large leaves, the stem size of a walking-stick, height under 5 feet, pot No. 16, and what more could stamp it for the smallest greenhouse? and some such consideration runs through the whole selection. *Acacia pentadena*, after *Drummondii*; *Acacia grandiflora*, after *grandis*, *suaveolens*, *Riceana*, *Drummondii*, *myrtifolia*, *sulcata*, *paradoxa*, *grandis*, *pulehiella*, *floribunda*, *grandiflora elegans*, *ovata*, *decipiens*, *premorsu*, *argyrophylla*, for its silvery, silky, shining leaves; *marginata*, after *cecastrifolia*. All these are as easy to keep as *Fuchsias*, and bloom, or may be bloomed, from the new year to April in a common greenhouse, and be out of doors from May to October. Some of them as standards, like standard *Roses*, would do admirably in the centre of flower-beds along the side of walks, or where there was no aim at composition-planting of beds.

The climbers in this large house are also well worth the attention of those who may be in want of such high decoration. They begin with the various *Passion-Flowers* and *Taconias*—as *Passiflora cœrulea*, *racemosa*, *Neumanni*, *Goutierii* after *alata*; *Taconia mollissima* and *pinnatifida*. *Tecoma jasminoides* and others; *Kennedyia monophylla*, *rubicunda*, and several others of that family; *Jasminum azoricum*; *Bignonia capreolata*; *Hardenbergia* of sorts, including *digitata* and *ovata alba*; *Mimosa marginata*, or the old *prostrata*; *Rhynchospermum jasminoides*, which can also be forced to come into bloom any time in the winter; *Zichya villosa* and others; *Lyonsia straminea*, looking like a large-leaved *Kennedyia*; *Holboellia latifolia*, related to *Stauntonia*; *Physolabium Sterlingii*, from New Holland, and looking like some *Hardenbergia*, are the principal kinds in that

house. And there is a fine-leaved climber in the large succulent-house called *Cissus quinatus*, which is valued entirely for the healthy looks of its large, green, shining leaves, and its free healthy growth. Here is a *Passion-Flower* which blooms most part of the year, and is called *hybrida floribunda*—a dark blue flower. Here, also, is *Hardenbergia digitata* in full bloom.

Here the succulents are as gorgeous as they are grotesque. *Littæa gemminiflora* is called *Agave* here. Two kinds of *Dasy-lirion glaucum* and *acrostichum* are two most beautiful plants for setting out in summer on terrace gardens; also *Agave*, or *Littæa striata*, and *gemminiflora* both equally good. *Gemminiflora* flowered at Kew last year, and, four or five years back, at Claremont; but the plants did not die, like some *aloes* do, after flowering.

In a forcing-house for cuttings and for supplying the show-house, lots of *Baron Hugel Geraniums* were in bloom as free as on a ribbon-border from the beginning of March. The *Baron* is the best of all *Scarlet Geraniums* for winter work; but one, like *Tom Thunab*, and called *Right's Queen*, is the best spring *Scarlet* brought to Covent Garden after being forced. The rafters were alive with *Tropæolum Lobbianum*—the best of all the winter bloomers, especially if it receive a few more degrees of heat than a common greenhouse. The plants were in No. 16-pots. *Fuchsias* for summer decoration; also large specimens of the *Unique Geranium*—the best in-door plant of the whole family in July, August, and September. Here, also, were shelves of *Brilliant* variegated *Geranium* in full bloom; *Calceolaria violacea*—a useful plant for spring use; *Cinerarias*, *Kalmias*, *Heliotropes*, and no end of *Flower of the Day*, and other bedding beauties; and a long, deep pit of twelve lights, just outside, was full of variegated *Geraniums* of sorts, still in store-pots for want of room.

My old favourite, *Lupageria rosea*, in the cold, or cool Fern-house, is now in a No. 1 or No. 2-pot, and growing and blooming as freely as ever. The Ferns make a forest in the rest of the house. Next to the propagating department—and there is a good day's work for bookmaking if one could spare the time—one thousand *Stachys lanata* for permanent bedding, all just rooted; *Arabis variegata* the same; *Frosted Silver Plants*; *Tropæolums*, *Gazanias*, and especially *splendens* in myriads; besides the *Verbenas*, and all the old requisites of that turn and style, with indications of a still higher strain.

What would you say to a hundred yards of *Cantauria candidissima* as the second row on a ribbon-border? Or to a full-length fourth line with a Fern variegated to vie with—what shall I say?—*Brilliant* in prime mood? The *candidissima* will do certainly when one can afford a ten-pound note for the hundred yards of it; but the variegated Fern is yet at so many half-guineas a-piece according to the size—the smallest size for the smallest piece of gold in circulation; but the plant seeds as free as poppies, and every seedling comes variegated, and will soon be as cheap as *Alma* for the ribbon-borders. It is the old *Pteris cretica* in a new dress from Java. Mr. Smith, who knows them better than any man living, says *cretica* is found in all parts of the world where Ferns grow; but this form of it is found only in Java. It grows 15 inches high, is of a quick, spreading habit, and sturdy growth, makes the finest exhibition plant of all the variegated kinds, is in all the London nurseries, and Mr. Linden is going to send it over for the ribbon-borders for the summer months. I am to prove it, and let you know: and the Floral Committee had a basketful of it from Mr. Veitch, and one plant from Mr. Bull the same day; and there is no mistake about it, for it took a first-rate prize, and no voice or word "to the contrary."

Camellia-horse in forcing for wood and early buds for next year. The *Sikkim Rhododendron-house* the same, but kept much cooler and more moist than the *Camellias*. Here, then, is an answer to "AN OLD SUBSCRIBER" or two, who have been wishing to know how to do the *Sikkims*. The plants there are glorious in their looks and luxuriance. They are kept as cool as *camellias* during the winter; and in the spring, when they move naturally into growth, they are very gently encouraged to grow freely in a moist atmosphere, and little sun, with a rise of a few degrees of heat. The turning-point in their management seems just the same as that for the *Nepaul great Rhododendron trees*—to see that all stimulus is avoided as soon as their growth is finished, lest they start a second growth, and thus hinder them from setting their flower-buds; also to take special notice that the sun does not strike heavily on their new leaves till they are quite ripe—or say to the end of September, or nearly so. When

the frost is over they are turned out doors, and the pots are half plunged in a sheltered piece of ground, which is shaded by trees from the mid-day sun, or where the sun can reach them only in the mornings and evenings, and their strong leathery leaves are supposed to need a vast deal of moisture from some damp mulching all over the ground among the pots, and round about where they stand during the whole summer.

The bulbous *Tropæolums* had a new device for training their slender threads on—thus: When the bulbs are potted, a strong stake is placed in the centre of the pot, and firméd there with copper wire—first across the top of the pot, and fastened to a wire round the rim, and secondly by another run across the first wire, the two forming an X in the centre, and fixing the stake at the cross. The stake is gimlet-bored all the way up; and twigs of old birch brooms are stuck into the holes to form a Christmas-tree-like support, or a dried spruce fir without leaves. There is even a leading-like shoot out of the top hole on the stake, and the whole is firm from the very first. The diameter at the surface of the pot is from 16 inches to 20 inches.

In the botanical propagating-house were the grandest sights. It was there that *Peris eretica albo lineata* was first proved from seeds, that *Cinchona Calisaya* will root slowly from cuttings and layers, that the largest Pea or Bean in the world is 5 inches in diameter, that it opens in two parts like a scarlet runner, and that three young sprouts for trees come from the same germ within it: that is the size and shape of the seeds of *Mora excelsa*, the most majestic tree of Guiana, according to Sir R. Schomburgk, who first discovered it, and says the timber is as good as that of our best oak. Glasses for growing Ferns and Finellas under are there on a new and economical plan—four large squares of glass set in a strong frame as for the bottom of a hand-light, and a moveable roof of two panes set at different angles like the roof of a house, and two small pieces of glass for the gables. The roof and gables come off like the top of a hand-light, but the bottom never if it could be helped, so as not to let the softest breeze or touch come nigh the great variety of *Hymenophyllums* and their allies which delight in such quiet retirement. But why not have the like and the same care for our cuttings? They, too, or some of them, dislike popping off and on of tumbler glasses, as much as film ferns anyhow.

In one of the tropical stores was a fine plant of *Meyenia erecta* in bloom, and there is a white-flowering kind of it at Kew; *Gardenia citriodora*, a fine thing; *Howardia caracacensis*, with brilliant pinkish bracts, as conspicuous that way as the white bracts of *Muscenda frondosa* itself; *Franciscia macrantha*, with very large flowers and leaves; *Ixoras*; *Gesneras*, of which *cinnabarina* is the queen; *Thunbergia Harrisii*, flowering free as gloxinias, and with the same shaped flower of a light blue colour—a famous stove climber for winter-flowering either in large pots or out in a free border; *Rixia glandulosa*, a fine thing; and the old *Plumbago rosea* done to a T at last, and blooming from November to March; *Linum tigrinum*, blooming as freely the whole winter; *Clerodendron splendens* ditto.

But one of the finest new winter bloomers is an *Acanthid* from the unfortunate Barter who perished in the late Niger expedition. This is called *Stephanophysum Baikiei*, after Capt. Baikie the Commander. The flower is of the shape and colour of *Thyracanthus rutilans*, only brighter, and the spikes of blooms are upright. The plant also is of a good habit, and is invaluable in large country collections. Another useful plant of the same class is *Dipteracanthus Kerhishi* from Rio, with more pink in it than in *stephanophysum*; *Allamanda nerifolia* in bloom as usual; *Callysandra hæmocephala*, a bottle-brush-looking flower of the Inga group; *Gleisomeria nitida*; and a very curious little *Aristolochia flavoites*, with a bulbous-like stem, producing a host of flowers all round the surface of the pot; the grand *Brownea coccinea* in full bloom, large heads of drooping crimson scarlet flowers of vivid lustre. To make out the circle of economies, they grow their own coffee, tea, and tobacco.

In the first Orchid-house was a spotted or variegated something, like a little Mexican maxillaria, with round white dots all over the leaves. It was found by Mr. Ross, of *Cinchona* celebrity, in the forests of Guauquil—the only one of the kind he had seen among thousands of common *Oncidiums*, which made the forest blaze as our commons do when the Gorse is in bloom. The Indian Orchids are in the first house, and coming away in grand style, with the stronger *Oncidiums* at the coldest end coming into bloom freely as in that forest. The next is the *Victoria*-house, in which victory is won already in fine-leaved and

variegated plants. The leaves of *Cyanophyllum magnificum* are 35 inches long and 16 inches across. *Eucharis grandiflora*, in a No. 8-pot, with six or seven bloom-spikes—pitchers planted out in peat-borders, and rambling over everything, and they get them from seeds to pitcher from the first; *Æschynanthus* of sorts, hanging over the Lily-lake in beautiful ringlets; and *Colocasia edulis variegata*, the very best of all good things of that stamp.

The last house I went through was the alpine Orchid-house, or where the Mexican and other hardier kinds are kept. Here, too, was a fine display of various flowers—as *Begonias*, *Gesneras*, *Bletias*, *Dendrobiums*, *Lycastes*, *Cypripediums*, *Epidendrums*, and *Gloriosa superba*, all in bloom. *Gesnera cinnabarina*, in a long vista row in this house was the richest colour I ever set my eye on; and there was a climber on one of the rafters which was new to me—a *Littonia modesta*, with the exact habit of a twining bonarea, and the looks of a gloriosa, with pale yellow drooping flowers. In another store was a new way of doing *Platycerium grande*. It was tied to a log which was hollow in the centre, and through a hole the roots got inside, the hollow being filled like a garden-pot, and the plant grew amazingly, and preserved its barren leaves or fronds in the most healthy state, which it never does in pots or any way where it touches a damp surface. But the way to understand this is to suppose a pair of new top boots to be filled with the right compost for that Fern, to have holes at heel and toe for drainage, to pin a young *Platycerium* against the top part of the boot outside, and to make some slits over the calf of the boot to let in the roots to the mould, to water from the top of the boot, and let no water rest on the folds of the fronde viridi.

D. BEATON.

VINERY AND CUCUMBER-HOUSE COMBINED.

I HAVE a vinery heated with hot water (four-inch pipes flow and return), and being very anxious to build a Cucumber-house—say 12 feet long by 6 feet wide, could I not attach it to the end of my vinery, and by taking off the syphon and air-pipe put another 6 feet of flow and return pipe on, so carry it through a tank to be placed in the Cucumber-house underneath the bed where the Cucumbers would be cultivated? By this plan I should save the expense of a boiler, and only use one fire instead of two.—B. Z. ARMISTRO. G.

[Unless your vinery is very large, a small boiler will do easily all you propose; but then the heat must all pass through the vinery before reaching the Cucumber-house, so that you cannot heat the latter without heating the former. Perhaps you do not mind this, and will prefer heating them simultaneously. You could also, in the case of early Cucumbers, have more heat there than in the vinery by giving more air in the latter. We should carry the pipes all the length of the Cucumber-house with or without the tank. We find no fault with the latter, only the expense. The pipes and plenty of them, according to the season of the year, would give us all that we should require; but by all means have a tank if you prefer it as a hobby. If you had your Cucumber-house on the other side you might easily heat it independently of the vinery from the same boiler.]

A GLIMPSE OF WOODHALL.

THIS celebrated place, the country residence of Abel Smith, Esq., is about four miles from Hertford. I visited it on the 8th of February, the same day as that on which I called at the Hertford Nurseries; and though it was a very unsuitable time of the year to visit a fine garden and I took no notes, some impressions and recollections may be worth recording.

However the traveller goes from Hertford to Woodhall, he will pass through a varied, picturesque, and well-cultivated part of the country. The park itself is very large, much varied in outline, and well supplied, perhaps in places too densely supplied, with timber. When trees for a large space stand thickly together, we are more impressed with the ideas connected with the utility of a forest than with the more refined associations connected with massive groups in a park comparatively open. It is always, however, an easy matter to cut down and thus admit, not only of diversified light and shade, but of great variety in outline. Large breadths of Bracken Fern add to the picturesque beauty.

The mansion, so far as I recollect, is more massive and com-

modions than ornamental in its architecture. It stands on the edge of an elevated platform, the carriage entrance being on the north-east side, with a small lawn in front of it. On this lawn fine plants of *Pinus insignis* seemed quite killed; *Araucarias* had suffered severely; *Deodars* were brown and white, but would recover; and such plants as *Cupressus funebris* and *Lambertiana*, were killed outright. There was a pretty little thriving plant of the *Abies elegans*, with which I was unacquainted, quite as hardy as the common spruce, and seeming to have a fine habit of growth. Common Laurels and Portugal Laurels had suffered severely, and *Laurustinus* were next to killed. A slightly raised walk bounded this lawn; and on one side at least it passed through a rough shrubbery, where Mr. Beale intended forming a rockery and fernery.

The wood in the park in front of this lawn had been thinned with great propriety, so as to bring a number of fine Cedars about forty years of age within view of the windows of the house. Just as I stated some time ago in the case of Gorhambury, a fine effect would be produced by an avenue of *Deodars* between this lawn and the kitchen garden.

On what I may call the east side of the mansion is a flower garden somewhat sunk, and, of course, in February having little attraction, backed by a small conservatory, the front facing that end of the mansion. The roof was a perfect picture of long yellow racemes of a fine glaucous-leaved variety of *Acacia pubescens*. The two beds were supplied with fine plants of *Camellias*, *Oranges*, &c., grown in pots, but plunged so as to conceal the pots, and enable the visitor to look down chiefly on the flowers instead of looking up to them. Some fine *Acacias* and creepers were growing against the pillars; and the front shelf was very gay with bulbs, *Cinerarias*, *Epacris*, &c. Nicely, however, as this conservatory looked, it seemed to me to detract, even by its smallness, from the massive grandeur of the mansion; and having no direct connection with it, the interest was to a great extent lessened, as ladies could get to it only on fine days. No position could be more appropriate for a conservatory worthy of the mansion and of the demesne; and by doing away with the flower garden, the new conservatory could be connected with the mansion by a wide promenade all covered with glass and with plants on each side. The conservatory, as a whole, would then resemble the letter T, and if deemed desirable a small artistic parterre might be placed on each side of the long leg of the T. In these days of cheap glass, such structures connected with a mansion must be a great source alike of health and rational enjoyment. Those possessed of the means might thus, to a great extent, enjoy a Torquay, a Naples, or a Madeira, not far from their parlour fireplace.

The fine panoramic views from the south-west side of the mansion will, however, chiefly attract the attention of the visitor. The ground for a great distance slopes somewhat gradually through an open park to the river Beane, and then rises seemingly more variedly as far as the eye can reach. The front of the house has a wide grass terrace bounded by a gravel walk and a terrace wall. The terrace at my visit had some clumps of low evergreens, &c., but it was to be entirely remodelled. Unless when close to the lower windows, the height of the terrace wall intercepted the view of the silver waters of the Beane. That wall was to be removed, that the eye of a person sitting in any part of the lower rooms could take in the whole scene. In front of that wall in part of the park a new geometrical flower garden is to be formed, with fountains and other accompaniments, and then, lovely as the scene now is, it will be lovelier still. I shall count on the pleasure of seeing it some June or July.

Few can gaze on such a demesne of a hundred thousand acres and say literally "It is mine;" and yet every one permitted to look upon such scenes, and possessing the large-heartedness that prevents the intrusion of a spark of envy or discontent, may make all that beauty his own, and realise as much pleasure in contemplating it as the benevolent proprietor himself. I have several times in these pages given utterance to these ideas, though with little of the force and beauty presented in the following extract from the last work of the great statesman and writer of Hertfordshire, and which I commend to the attention of all those especially who visit places and gardens that they think much finer than their own.

"The grey cripple and the bright-haired child often paused and gazed upon the demesnes and homes of owners whose lots were cast in such pleasant places. But there was no grudging envy in their gaze, perhaps because their life was too remote

from such grand belongings, and, therefore, they could enjoy and possess every banquet of the eye. For at least the beauty of what we see is ours for the moment, on the simple condition that we do not covet the thing which gives to our eye that beauty. As the measureless sky, and the unnumbered stars, are equally granted to king and beggars, and in our wildest ambition we do not sigh for a monopoly of the empyrean, or the fee simple of the planets; so the earth, too, with all its fenced gardens, and embattled walls, all its landmarks of stern property and churlish ownership, is ours too, by right of eye—ours to gaze on the fair possessions with such delight as the eye can give, grudging to the unseen owner his other, and, it may be, more troubled rights, as little as we grudge an astral proprietor his acres of light in Capricorn. Benign is the law which saith, 'Thou shalt not covet.'"—R. FISU.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE.—A Meeting of this Committee was held on Tuesday last, Rev. Joshua Dix in the chair. The room was liberally decorated with a profusion of fine plants and flowers. Among the most conspicuous were a table filled with very fine specimens of Indian *Azaleas*, another with a splendid collection of *Anriculas* and forced *Roses*, and a third with *Pelargoniums* from Mr. Charles Turner, of Slough, for which he received three Special Certificates and the thanks of the Committee. Messrs. Cutbush, of Highgate, sent a very nice collection of *Hyacinths* in pots, to which a Special Certificate was awarded; and a letter of thanks was voted to Mr. Young, West Hill House, Highgate, for a collection of bedding *Tulips* in pots.

Mr. Turner, of Slough, sent a seedling *Scarlet Geranium* called *Herald of Spring*—a large flower with good truss, and of a fine orange cerise colour, to which a First-class Certificate was awarded. The same gentleman also sent *Queen of Scarlets*, a dwarf variety, *Fairholmsland*, a rosy white and pretty, and *Prince of Hesse*, a fine large flower of a salmon colour, shading off to the edges. These were more or less admired and requested to be seen again. Clara, a seedling *Scarlet Geranium*, of fine shape, received a Label of Commendation. The leaf is finely marked with a dark disk and a darker zone, yellowish-green margin, with an orange zone when young, and with large, deep crimson scarlet flowers.

Mr. Bull, of Chelsea, sent a hardy *Heath* with a white flower, which was called *Erica mediterranea alba*, but which had no resemblance to *mediterranea* in habit, being a dwarf dense plant like *herbacea* in its growth. Also *Thrinax elegans*, a pretty little stove Palm which has been some years in cultivation, and which is the *Thrinax radiata* of Loddiges and of Martius. Mr. Bull also sent a collection of *Variegated Begonias*, and a box of *Agathaea celestis*.

A box of flowers of *Bougainvillea speciosa* came from Mr. Daniel, of Henley-on-Thames, and were certainly the admired of all admirers. Dr. Lindley has shown that this is not, as was formerly supposed, the *Bougainvillea spectabilis* of Lamarek, but a distinct species altogether, and which he has named *speciosa*. Dried specimens of both species were exhibited by Dr. Lindley, and the difference was at once apparent. A Special Certificate was awarded. Messrs. Lee, of Hammersmith, exhibited a lovely Fern called *Lomaria cycadifolia*, which produces a globular stem or stipes like a *Cycas*. It was awarded a First-class Certificate, as were also two other beautiful Ferns—*Lomaria fluviatilis*, and *Polystichum vestitum*, var. *venustum*.

Mr. W. Wilson Saunders, sent *Prenanthes pinnata*, and *Prenanthes arborea*, the latter a pretty-foliaged plant, which was awarded a Label of Commendation. The same gentleman also sent a pretty, delicate-stemmed, rambling, small-leaved species of *Asparagus*, and a pretty plant called *Erodium guttatum* with purple flower, and a dark spot at the base of each of the petals. The latter received a Label of Commendation.

Mr. Veitch, of the Royal Exotic Nursery, Chelsea, sent a free-blooming, dwarf-growing *Pultenea*, called *Gilesii*, and *Erica imperatrix*, the latter a seedling of Mr. Storey's. From the same nursery came a beautiful-foliaged new plant called *Adelaster albinus*, an acanthaceous-looking plant, related to *Justicia*, with long, ovate-lanceolate velvety leaves, of a very dark green tinged with purple, and with pure white veins. It was awarded a Label of Commendation, but deserved a higher award.

Among other articles exhibited, we observed a large basketful

of very fine *Mushrooms* grown by Mr. Young, gardener to R. Barclay, Esq., West Hill House, Highgate, produced from Cutbush's Mill-rack spawn.

EFFECTS OF LAST WINTER UPON PLANTS IN VARIOUS PARTS OF ENGLAND.

(Continued from page 60.)

I HAVE for many years remarked the effects of our severe winters, and have seldom or never known them to extend with a like result over the whole of England. One severe season has been remarkable for killing the evergreens in the neighbourhood of London—the warm sheltered valley of the Thames, and in Surrey; leaving unscathed those in the home counties to the north and east of London. Another severe winter has passed over these districts with effects exactly the reverse. As a general rule, the hills in Sussex and in the south of England rarely have their evergreens injured by the frosts of midwinter; but have suffered, if at all, by the dry cold winds of March. The Christmas frost of 1860 seems to have been nearly equally severe over a very large tract of country, including the northern, eastern, north-western, and home counties nearly as far south as the Thames valley, over which the frost does not seem to have passed with equal severity; for while at Chiswick the lowest temperature was 7°, at only a few miles to the north-east, as at Ware, it was —1°.

The destruction of what we fondly hoped were acclimatised coniferous trees and shrubs over this large district is enormous—quite beyond all precedent; for never in gardening annals were so many choice *quasi* hardy trees and shrubs to be seen in our gardens and pleasure-grounds as in the autumn of 1860. In the north, at Darlington, in the nursery of Mr. Harrison, *Deodars* and *Arancarias* are all completely killed down; and all his *Roses*, even the stocks of the *Dog Rose* planted in 1859, with live buds in them, are also killed. Common *Hollies*, and *Portugal Laurels* even, are leafless and brown. It is also reported that the large stocks of *Arancarias* and *Deodars* in the Liverpool nurseries, more, perhaps, than in the whole kingdom, are all killed. In the large district I have above alluded to, the *Cypress* tribe seems to have suffered greatly. Large and small trees alike of *Cupressus macrocarpa*, *C. Goveniana*, *C. Knightii*, *C. funebris*, *C. majestica*, *C. sempervirens* with its varieties, *C. torulosa*, *C. Uldema*, *C. Benthiana*—in short, all but *C. Lawsoniana* and *C. nutkaensis* (*Thuopsis borealis*), are among the things that were and never more to be considered hardy—a term of late years so often misapplied to new trees and shrubs. One cannot but lament this: for *Cupressus macrocarpa*, and two or three species besides, bid fair to be such permanent and beautiful evergreen and ever-pleasing ornaments to our gardens.

In great contrast to the *Cypress* family are the *Arbor Vitæ* (*Biotas* and *Thujas*). The Chinese *Arbor Vitæ* (*Biotas*), have borne the temperature of the eastern and home counties bravely; and that very pretty, small-leaved, bright green variety called *Biota compacta* better, perhaps, than any other; for in the species, and even with *B. aurea*, some browned shoots are to be found. We need not feel surprised at this, for the Chinese *Arbor Vitæ* is remarkable for its hardiness: witness its growing so freely about Paris (a death-dealing place to evergreens), more particularly in *Père la Chaise*, where there are thousands of trees of all sizes. *Thuja gigantea* and *T. Lobbii* seem to have stood the winter perfectly unscathed, and seem as if they would partly compensate for the great losses we have sustained among *Cypresses*, two only of which, if we make *Thuopsis* a *Cypress*, are to be depended upon—viz., *C. Lawsoniana* and *C. nutkaensis*.

Among the true *Pines* it is much to be regretted that the beautiful *Pinus insignis* is in most places quite killed, or so injured as to cease to be ornamental. All, or nearly all, of the Mexican *Pines* so largely introduced of late seem totally destroyed. The *Silver Firs*, as well as all the species and varieties of the *Spruce Fir*, seem in all situations entirely to have escaped injury, which is a great comfort to the lover of coniferous trees, for among them are the most beautiful of trees. The *Junipers*, with some few exceptions, seem to have stood the winter well. The exceptions, so far as I have seen, are *J. Bedfordiana*, *J. gossainthiana*, and *J. macrocarpa*. *Libocedrus chilensis* seems to be totally destroyed. The *Yews* of all kinds appear scarcely to have a leaf injured. *Wellingtonia* in most places has escaped without injury. I have, however, observed that in some exposed

situations a great number of its young shoots are brown and dead, and are now falling off; still, its leading shoots are safe, so that but little disfigurement will take place.

One of the most remarkable effects of the late winter is the destruction in the district I have mentioned of the evergreen Oaks (*Ilex*). Nearly all the trees I have seen, whether old or young, seem totally destroyed. At Hunsdon House, near Ware, Herts, large trees upwards of a century old are killed; their branches and stems not slightly browned as they were last year, but perfectly sear. The *Lucombe Oaks* are also, many of them, too far gone to recover. Trees of the narrow-leaved sort, called the new *Lucombe Oak*, seem to be quite dead, their stems and branches as sear as those of the *Ilex*.

As to common *Laurels*, the pride of our gardens, *Laurustinus*, *Bays*, and a host of other evergreens, they are among things of the past. I may, however, mention that at Epping, lying very high, and the soil a heavy retentive clay, the evergreens of all kinds are nearly unimpaired.—*QUERCUS*.

HINTS ON MELON GROWING.

THE past season of 1860 to a goodly number of Melon growers proved a perverse one, and it certainly told as much relative to this species of fruit, as about any other that was grown, driving not a few to their wit's end.

The fruit's seemingly natural propensities to crack were a regular poser to even some of our best growers, although brought on in a great measure by themselves.

That it was an excessively trying season to every grower there is not a doubt, and there are but very few that can remember such a season before. It seemed a general complaint, for go where you would amongst the gardening community one question was sure to be asked—"How are your Melons? are they cracked?" and I was told by several that theirs cracked long before ripe. Why was it?

Various were the reasons assigned for their cracking: but the majority that I came in contact with attributed it to want of sun. Was this the whole and sole cause of their cracking? No. Although it must be admitted that there was an unusually limited number of sunny days in comparison with the corresponding summer months of years upon years gone by, and, naturally, if there is a deficiency of sun you are told there must be a deficiency of power to abstract that excess of moisture the plants were continually endeavouring to eject, or that ought to evaporate from them. It might be justly termed a trial year for Melon growers, and leaving only the one road open for those that then failed, which is to try again.

But, generally speaking, the Melon plants that came under my notice suffered more when about three-parts ripe or grown, from excess of moisture at the roots and want of sufficient air than from want of sun. Excess of moisture at the roots is far too often caused by inefficient drainage, which is of the most imperative necessity for the successful culture of this well-known fruit. Inefficient drainage also takes the command of the beds entirely from any one's hands. Inefficient drainage is also in direct opposition to obtaining that great desideratum, a rich flavour, which is so required, and which they must have, or whoever is the grower will fall far short of ranking amongst the best growers of his day.

Much more might be said on the evils that accrue from non-efficient drainage of the plants. See the havoc the over-abundant supply of sap causes at the setting and first swelling of the fruits, for these swell to excess. Yet, eventually, the inefficient drainage destroys a great portion of the principal fibrous rootlets or thread-like feeders of the roots of the plants, causing the fruits to turn off one after another, leaving in the end perhaps from three to six inferior fruits in a two-light frame, instead of the same number three times told, and those which remain are scarcely worthy of the place generally allotted them when placed on the dessert table.

There are many that are impressed with the idea that the Melon is of the most easy culture; but that idea is erroneous, for of all the fruits that are cultivated on this isle few require more care and attention than this does, and few repay better than this for the care and attention they receive.

Some will fail this year, and will continue to do so, for are they not planted in many instances (although not by all growers), without considering for a moment the natural habits of the plants? In some cases they are grown far too luxuriantly to

produce many fruits; while in other instances through mismanagement, they form a feast for the red spider and other insects before any of the fruit is ripened at all.

The most essential points to be borne in mind for good Melon growing are these:—

First, the imperative necessity for thorough drainage for the plants. Secondly, the greatest care and attention to giving them constant and regular ventilation.

For the drainage, broken potsherds might be used rather freely in a similar manner as for pot plants, to be mixed with the compost for growing them in.

The compost used here is a rich turfy loam chopped to about the size of walnuts, with about one-third of old mushroom-bed and leaf mould combined. This the plants fruit most freely in. They have never more than from 1 foot to 15 inches deep of this compost to grow in, which I far prefer to a greater depth—that is, on dung-beds. Here they are grown on them with the greatest success in a most simple manner, outweighing all that I have ever grown, either in a house or hot-water pits.—A. J. ASHMAN.

(To be continued.)

CULTURE OF TRUFFLES.

WITHOUT being able to name either particular persons or particular places, where and by whom the experiment has been tried, I think that certainly not less than seven or eight different persons have, all of them, informed us they could never succeed in raising the Truffle artificially, although every pains was taken in procuring the soil from the very identical spots where the Truffle is obtained in tolerable abundance—in those parts of Hampshire about Cheriton and Alresford; and we also know that in those particular spots where they have been plentiful one year, they may be scarce or altogether absent in another or the following season.—T. TAYLOR, *Covent Garden*.

In answer to your inquiry about Truffles, I know that they are in great request in some parts of France, but little is known about their propagation. Having the “*Bon Jardinier*,” I translate the following:—“*TRUFFLES (Lycoperdon tuber)*, an extremely singular vegetable, having neither stems, leaves, nor roots; consisting simply of a kind of dark or white tuber, according to the variety, always hidden under ground. Nothing is known of its propagation. They are found chiefly in the autumn, especially at the roots of the oak. Their cultivation has been tried, but without any real success.” All I can say to your “*OLD SUBSCRIBER*” is that it is difficult to throw a light on a matter of thing which delights to be in the dark.—E. PERSAC, *Exeter*.

A CORRESPONDENT has obligingly forwarded us the following cutting from a newspaper, but without either date or name:—

“Next to wine and corn, I believe the crop of Truffles stands highest in the estimation of Parisians; and it is not surprising that tubercles, which sometimes cost 16s. to 20s. a-pound, as these did last year, should be regarded with great interest. Fashion or taste fixes the value, and such prices give importance to the commodity in a commercial point of view. These dainty fungi are now coming to market, and are fetching 10 to 20 francs the kilogramme, but it is expected that the lower price will reach 15 francs by Christmas. Périgord, Comtat, Provence, and Dauphiny produce the finest Truffles. The demand for them increases rapidly, and, in spite of the cultivation which has been carried on to a great extent in some parts, the supply is insufficient. An important discovery has, however, been made. Africa, whence Pliny, Apicius, and Lucullus imported Truffles at a great cost, produces in some parts large quantities of the black specimen of a delicate texture and delicious aroma. A large house of business in the Drôme, which has been engaged in the trade for a century, has lately extended its operations to Algeria, and a considerable quantity of new supplies has already been received from the colony in question. A curious fact has been brought to light by this adventure in search of seasoning. In France Truffles are almost always found near oaks and hornbeams, but in Africa they seem to prefer the neighbourhood of pines and cedars, and are often found far away from any tree whatever. This seems to put an end to the theory of the Truffle fly picking the roots of the trees, and thereby causing

the growth of the tubercle; or, in the words of a correspondent, this insect and his exploits are the fruit of imagination. If this be true, it is very hard upon those who have been taught to watch and calculate the effect of the seasons on this interesting gastronomic purveyor. As an instance of the faith that is placed in the fly theory, I may quote what was stated the other day in the *Périgord*, not *paté*, but newspaper. A writer in the journal which has such an appetising word in its title says:—“When the ground is very hard the flies cannot descend to the roots of the trees; but this season, as the months of July and August were sufficiently moist, the crop of Truffles is likely to be large.” If the insects are to be given up, the theory that a wet July and August bring a good crop may still be maintained.

“The consumption of oysters here is immense. If any disease should seize that interesting family, we shall certainly all be carried off; and scientific men are doing their best to increase the danger, by converting the coasts of France, both in the Channel or in the Mediterranean, into huge colonies of natives. Messrs. Cloquet and Coste have supplied us of late with much information relative to the propagation of these fishes, and the latter gentleman has been furnished with a steamer called the *Chamois*, by the Emperor, for the purpose of picking them up and planting them in the most advantageous manner. At St. Marc, Côtes du Nord, the success of the new beds has been very great. Three hundred fascines were moored to the banks in June 1859, in order to afford shelter to the young oysters; and three of these, being taken up last year, were found to contain the enormous quantity of nearly 20,000, measuring from 1 inch to 2 inches in diameter. The fascines thus loaded were exposed to public view at Bric and Portrieux for several days. It is said that the beds in the bay of St. Briac have obtained such celebrity abroad that M. Van Beneden of Louvain, M. Eschricht of Copenhagen, and many other foreign scientific men, have visited the place in order to study the system and apply it in their own countries. The next step undertaken by M. Coste was the *plantation* of oysters above the low sea line, in order, to quote his words, to see if they could not be *grown, protected, and gathered* with the same facility as the *peaches in our gardens*. He published his views upon this subject in 1855, and has since been busily employed in carrying them out. The basin of Arcachon has been converted into a vast oyster park: 112 capitalists and sailors are associated in the business; and 200 acres, which are covered by the sea at high water, are now producing large quantities of fish. The Government, in order to assist the undertaking, has established two model oyster farms on the spot, where experiments are made in the necessary operations of *sowing and gathering*. The beds are arranged with fascines, kept in their places by bricks, cement, and planks in geometrical order, and each part is literally covered with oysters of every age, from the mere infant to the bearded old grandfather. A single tile has been found to support a thousand shells, and M. Coste exhibited some very remarkable specimens the other day at the meeting of the Academy of Sciences. Within two years parks extending along the coast for about four leagues have been formed in the Isle of Ré, opposite Rochelle. Fifteen hundred of these are now in full activity, and 2000 more are being planted. The oysters are said to average 600 to the square metre; and as there are 630,000 mètres under cultivation, the crop is now somewhere about 378,000,000, and is valued at about seven millions of francs. It appears that all the *seed* oysters have not been obtained from the ocean, for about 500,000 were taken by the Chamois last year on the English coast; these were deposited at Thau and Toulon.”

KEENS' SEEDLING STRAWBERRY BLOOMS GOING BLIND.

At the beginning of August last year I replanted a small piece of ground with Strawberries (Keens' Seedling). The runners were the very first from the old plants, and laid into pots, and I was particularly careful to take them from plants which had borne fruit. The ground was well mulched with stable-dung before gathering the previous crop, and the young plants were well dressed with fowls'-dung laid between the rows, which they seemed to luxuriate in. To my great vexation they nearly all appear to be blind, and are beginning to put forth runners. Can you inform me the reason why? I am the more surprised, as on the same piece of land there are some British Queens which were put in rather later, and which are

nearly all trussing up. Will the Keens' Seedling bear next year if I let them remain? I am inclined to think they will not, although some of my neighbours say they will.—C. H. C.

[We never met with such a case of Keens' Seedling. Without any selection whatever, we hardly ever have a barren plant. We can ascribe it to nothing but the extra care and the extra manuring you have given them, which have kept the plants in

vigorous luxuriance when they ought to be ripening their buds. The late planting seems to have done this for the Queens in spite of you. We should leave the Keens' alone, and if you remove the runners, and give all the sunlight to the plants possible, we have no doubt you will have a wonderful crop next year. Under your treatment the wet and dull autumn was much against you.]

NEW PLANTS FROM JAPAN.

PICEA VEITCHI—Veitch' Silver Fir.

shoots are hairy. The cones are from 2½ inches to 2½ inches long, and about 1 inch in diameter and are like those of a small silver fir.

INSECT RAVAGERS OF THE ROSE.—No. 1.

THE gardener has about twelve insect marauders from whose inroads he has to protect his Roses. Those which attack the flowers are most fatal to his decorative intentions, but those which attack the leaves are not slightly disfiguring and injurious. We will commence with three of these.

THE LEAF-CUTTER BEE (*Apis centuncularis* of Linnaeus and Kirby, *Magachile centuncularis* of Latreille.) Every cultivator of the Rose must have noticed semicircular cuts made in the edge of its leaves with as much accuracy as if done by a mathematical instrument. These segmental cuts are the work of the Leaf-cutter Bee and made by its mandibles. Messrs. Kirby and Spence have described the proceeding as follows:—

"The mother bee first excavates a cylindrical hole 8 inches or 10 inches long, in a horizontal direction, either in the ground or in the trunk of a rotten willow tree, or occasionally in other decaying wood. Latreille says the nest is also made in the earth. This cavity she fills with six or seven cells wholly composed of portions of leaf, of the shape of a thimble, the convex end of one closely fitting into the open end of another. Her first process is to form the exterior coating, which is composed of three or four pieces of larger dimensions than the rest, and of an oval form. The second coating is formed of portions of equal size, narrow at one end but gradually widening towards the other, where the width equals half the length. One side of these pieces is the serrate margin of the leaf from which it was taken, which, as the pieces are made to lap one over the other, is kept on the outside, and that which has been cut within. The little animal now forms a third coating of similar materials, the middle of which, as the most skilful workman would do in similar circumstances, she places over the margins of those that form the first tube, thus covering

and strengthening the junctures. Repeating the same process, she gives a fourth and sometimes a fifth coating to her nest, taking care, at the closed end or narrow extremity of the cell, to bend the leaves so as to form a convex termination. Having thus finished a cell, her next business is to fill it to within half a line of the orifice, with a rose-coloured conserve composed of honey and pollen, usually collected from the flowers of thistles; and then having deposited her egg, she closes the orifice with three pieces of leaf so exactly circular, that a pair of compasses could not define their margin with more truth; and coinciding so precisely with the walls of the cell, as to be retained in their situation merely by the nicety of their adaptation. After this covering is fitted in, there remains still a concavity which receives

Among the many new things sent home by Mr. John G. Veitch there are several Conifers, some of which have been hitherto undescribed, and, in fact, unknown until discovered by him in his journeys to the interior of Japan. Of these the subject of our present illustration is one which Dr. Lindley has dedicated in honour of the discoverer under the name of *Abies Veitchii*. Mr. Veitch met with it in his ascent of Mount Fusi Yama, where it attains the height of 120 feet to 140 feet. He describes it as being intermediate between *Picea nobilis* and *P. Nordmanniana*, and it will doubtless prove a valuable acquisition to our already excellent collections of Conifers.

The leaves are from half an inch to an inch long, glaucous beneath, and all turned to one side on the shoots, and the

the convex end of the succeeding cell; and in this manner the indefatigable little animal proceeds until she has completed the six or seven cells which compose her cylinder.

"The process which one of these bees employs in cutting the pieces of leaf that compose her nest is worthy of attention. Nothing can be more expeditious: she is not longer about it than we should be with a pair of scissors. After hovering for some moments over a Rose bush, as if to reconnoitre the ground, the bee alights upon the leaf which she has selected, usually taking her station upon its edge so that the margin passes between her legs. With her strong mandibles she cuts without intermission in a curve line so as to detach a triangular portion. When this hangs by the last fibre, lest its weight should carry her to the ground, she balances her little wings for flight, and the very moment it parts from the leaf flies off with it in triumph; the detached portion remaining bent between her legs in a direction perpendicular to her body. Thus without rule or compasses do these diminutive creatures mete out the materials of their work into portions of an ellipse, into ovals or circles, accurately accommodating the dimensions of the several pieces of each figure to each other. What other architect could carry impressed upon the tablet of his memory the entire idea of the edifice which he has to erect, and, destitute of square or plumb-line, cut out his materials in their exact dimensions without making a single mistake? Yet this is what our little bee invariably does. So far are human art and reason excelled by the teaching of the Almighty."

Fig. 1.

This bee lives alone, belonging to the group of solitaires. The body is about half an inch long. The female, which is the leaf-cutter, is black, covered with ashy-coloured hairs; jaws or mandibles large, terminating in four teeth; antennæ black, rather longer than the head; wings slightly transparent, dark tipped, veins black; legs hairy, spurs dull red, pollen brushes of hind legs golden; abdomen heart-shaped. The male's body thickly covered with yellow hair; antennæ longer than head; jaws two-toothed; dense yellow beard between the antennæ; fore thighs dirty yellow at the outward tip; abdomen rather oval, extremity inflexed, obsoletely toothed.

MICROSETIA CENTIFOLIOLA.—The leaf marked *f* in the preceding drawing shows the mining of the larvæ of a most minute moth bearing the name we have prefixed. The moth is only one-sixth of an inch across when its wings are expanded.

It is a most brilliant little creature, the body being golden with a purple gloss at the end, and the head red and woolly. The larvæ or grubs are orange-coloured, without legs, hatched from eggs deposited in the substance of the leaf during the spring. When ready to form cocoons they eat their way out of the leafy labyrinth they have formed, pass down the stem to the earth, and remain there until the time arrives for them to arise in the moth form.

LYDA INANITA.—For all the information we possess relative to this insect we are indebted to Mr. Westwood's notes in a work no longer published—"The Gardeners' Magazine of Botany." "For many years past we have regularly observed this insect in our garden at Hammersmith, in the last week in May and the first in June. It is constantly seen flying over, or settling upon, the leaves of the Rose, and its extremely glossy yellow wings, together with the rapidity of its movements render it quite a conspicuous object. Although, however, we have so repeatedly seen the insect, we have never yet been able to find a single male, all the individuals which we have observed and captured having been females. This sex measures five-twelfths of an inch in length, and the expansion of its forewings measures seven-eighths of an inch. The head and eyes are black; the front of the face, a heart-shaped spot between the antennæ, and a curved spot behind each eye, pale yellow. The jaws, palpi, and antennæ are also pale yellow, the extremity of the jaws being black, and the tips of the antennæ rather brownish. The thorax is black above, with the collar pale yellow on each

Fig. 2.

side. The abdomen is black, with the second, third, fourth, fifth, and terminal segments of a rich orange yellow. The legs are pale yellow, and the wings very glossy, and of a yellow tinge, with dark veins. Fig. 1. *e* represents the female of the natural size, and the woodcut (fig. 2), shows it magnified.

"The male, which is extremely rare (and for an opportunity of figuring which we are indebted to James Francis Stephens, Esq.,) is smaller than its partner, measuring only one-third of an inch in length, and five-eighths of an inch in the expansion of its wings, it differs also in being considerably darker in its colours; the antennæ being brown, except the two basal joints; the abdomen is black, the fourth and fifth segments being variegated with yellow, of which colour there are also spots at the sides of the preceding and following segments; the head is black beneath, with the sides pale yellow, the body

Fig. 3.

(including the whole of the abdomen), is pale yellow beneath, with the hind part of the mesosternum, and the greater part of the metasternum, black. The wings have very little of the yellow tinge of the female. The woodcut (fig. 3), shows the

male magnified in the same proportion as the female. We believe that no figure has hitherto been published of the male.

"At a later period of the year—namely, in the month of July and beginning of August, we met with a curious object on the same Rose trees which we are able at once to recognise as the larva of this Sawfly and its moveable case. Fig. 1, *d*, in the preceding cut, represents this larva with its head and the anterior segments of the body protruded out of the case, *b*, the wider part of which is formed of portions of the leaf upon which the larva is feeding, and which it has not yet actually detached from the leaf. Fig. *c* indicates the narrower part of the case formed of portions of other leaves; fig. *a* showing the opposite leaflet almost entirely stripped to its midrib; one portion having been consumed, and another portion employed in the construction of the narrower part of the case.

"The proceedings of this larva in the manufacture of its case are full of interest; it will be observed, for instance, that the instinct of the insect teaches it to arrange the narrow strips of the Rose leaf, of which the case is formed, in a spiral direction, that being the only method in which greater length can be given to the case, in order to keep pace with the increased size of the insect; the spire is kept in its position by means of silken threads, which the larva weaves from its mouth, and by which it attaches the mouth of the case to the leaf when it has finally detached the strip. As the soft skin of the larva requires a covering for a defence, so the insect, on the slightest alarm, withdraws into the mouth of the case, otherwise when it desires to feed it protrudes the front of the body for about a quarter of an inch out of the mouth of the case, and then gnaws the Rose leaf at its ease; the pair of legs at the end of its body enabling it to keep firm footing within. Now, it will be seen that the length to which the body is protruded is just the width of the strip of the leaf of which the case is made, and so it is that, commencing at one end of a leaf, it cuts away the strip, fastening it by degrees with silken threads to its house. Huber has given a very full account of the proceedings of a species with precisely similar habits, found upon the nut, a translation of which appeared in the 'Annals of Natural History' a few years ago. The curious reader will, in this memoir, notice not only the detail of the proceedings themselves, but the intensely inquiring mind of the author, whilst his name is a guarantee for the correctness of his observations."

FOREIGN CLIMATES AND PLANTS.

No. 4.

HAVING now left Nice for a rather more extended tour, it will be necessary somewhat to alter the heading of these letters. Most of the English and other winter visitors leave Nice on the return of the warm weather of spring. The power of the sun becomes so great that country excursions begin to get too hot in the middle of the day; and, consequently, large numbers take their departure during April, and the early part of May: so that by the end of that month it is almost deserted, except by those to whom sea bathing is an object. The Flower Show which I mentioned in a former letter as being about to be held at Nice, duly took place, and caused considerable interest, being the first thing of the kind there. Under these circumstances, of course, the perfection of London shows could not be expected; it was, however, very creditable as a beginning. One thing was rather against it: as it was set on foot by way of commemorating the anniversary of the annexation to France, and as all parties are not in favour of that movement, some did not cordially unite in promoting the matter. A new seedling Rhododendron was exhibited, white spotted with black, very pretty, to which the name of "Nice Français" was given. One immense bouquet was shown, the centre of which was white Camellias, in the form of a star; it was more than 6 feet in diameter. It may, perhaps, help our national pride a little, to say that our countryman, Mr. E. Stuart (whom I have before mentioned) took the prizes offered for three new Camellias, Collection of eut Roses (very fine), collection of Cinerarias, and for ten varieties of Stocks, which were much admired. As a rule, Camellias do not succeed well in this climate, it being too dry for them; they do much better in the open air on the banks of the lake of Como, where the atmosphere is moister, and there they attain a large size. As being different to the proceedings of shows in England generally, I may state that on the day following the close of the Exhibition, a public meeting (by announcement) was held,

at which a large number of persons were assembled, when the chief government officer, the Prefect of the Maritime Alps (M. Gavini), presided; and after a very laudatory speech, the prizes were distributed to the successful competitors.

The increased warmth of the atmosphere has, of course, considerably changed the appearance of the country. The numerous Plane trees are nearly in full leaf, so are also the Figs and Vines. The Horse Chestnuts and Hawthorn (it can hardly be called May here, as it blossoms in April), were in flower on the 2nd instant; Iris germanica (our large blue Flag), wild, and Apple trees, on the 6th; Judas trees and Lilacs are finely in blossom; and the Alpine Strawberries have, for the last fortnight, been sold in the market at Nice.

At the close of our meetings for the study of wild flowers, to which I before alluded, it was found that at the eight meetings upwards of 120 different kinds had been examined and discussed. Some of the dried collections were quite ornamental, as well as useful for future reference.

The drive from Nice to this place (Mentone), along the celebrated Cornice road, said to be one of the finest in Europe, is very splendid. The bright, green, fresh foliage of the Figs, Cherries, and other fruit trees contrasts well with the dusky dark appearance of the Olives standing out from the bare rocks. Near Turbia it attains an elevation of about 1800 feet, the aneroid barometer sinking upwards of 2 inches, and rising again on descending to Mentone on the sea level.

Almost the first thing which strikes a stranger entering the town is the constant stream of women Lemon-carriers, that fruit being very abundant and fine—just the opposite to Nice, where Oranges are principally grown. The Lemons are carried in the hot sun by women, barefooted, in open baskets, containing about 500 each, on their heads; they are of a great weight, being balanced by the overhanging ends of the cloths on which they are laid. It has very much the appearance of female slavery. The fruit is taken down to the ships for exportation to England, America, and other places; the price is from 1d. to 1½d. a-dozen. The Mesembryanthemum edule, or Hottentot Fig, flourishes upon the rocky banks; its magnificent pink blossoms expanded in the sun measuring 3 inches across. Gazania splendens is very fine in the gardens, and the size of the Stocks of various colours is enormous: in the evening the air is quite scented with their perfume.

The rare Ferns found in this district are the elegant Cheilanthes odora, Asplenium Petrarche, Gymnogramma leptophylla (very pretty and graceful, being annual in its habit), and the Asplenium Fontanum or Halleri. The two former are difficult of cultivation in England, but here they grow freely. I may mention that when at Nice I discovered another habitat of Pteris cretica in a damp valley, where the breath was visible as in a frosty day; it there attained the height of 3 feet.—E. COPLAND.

ZEPHYRANTHES PRATENSIS.

I HAVE a lovely bulb in bloom, which I purchased as Zephyranthes pratensis, but I can find no such name in any book to which I have access. Can you tell me anything about it? It is a bright vermilion red, with a green base to the flower, the stem bearing three flowers—unlike any Zephyranthes I have seen, the flower being generally solitary in that class. It rises about 18 inches high, the leaves narrow and strap-shaped, not erect. It is a beautiful thing, and I should like to know if that is its true name. It is not in London's "Hort. Brit." nor in the supplement.—A. R.

[No Zephyranthes has been named pratensis as far as we know; and if it had, your bulb could not be it, for by your description it is altogether out of the difficult group by which Zephyranthes is surrounded. A Zephyranthes with more than one flower on a stalk was never seen; and if it were, it would break down the most and best definition of the family. Your bulb seems to be a Phycella, or something that way. The "Wild Flowers of Great Britain" will be published "just as they come to hand."]

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, when cutting, allow the weak shoots to remain. *Beans*, make a sowing of Longpods and Windsor. When the early crops show bloom pinch off the tops. *Cauliflowers*, fork

up the soil surrounding them, and afterwards give them a good soaking of water, to be repeated frequently during dry weather. *Cucumbers*, prepare trenches for hand-glasses $2\frac{1}{2}$ feet wide and 1 foot below the surface, and then fill with prepared dung, leaves, and short grass 6 inches above the surface. Light, rich mould to be placed beneath the glasses, and the rest of the dung to be covered with the soil that came out of the trench. *Endive*, sow a little of the White Curled for an early crop. *Lettuce*, give a few of the earliest plants a good supply of water to bring them forward. Some of the *Cos* to be tied up to form heads. *Mushrooms*, if they should be required during the summer, make a bed now; they will keep longer in bearing, and the crop will be sounder and better during the hot summer months if a good portion of cowdung and loam is mixed with the droppings when making the bed. Water old beds when dry. *Tomatoes*, see that they are getting properly hardened off to be transferred to spare palings or open parts of the garden walls towards the middle of the month. Embrace every opportunity of destroying weeds and insects. Clear away all Cabbage and Broccoli stumps as soon as done with.

FLOWER GARDEN.

Old plants of *Chrysanthemums* planted at the foot of a wall in good rich soil will cover a wall 6 feet or 8 feet high by the autumn, and if properly trained will flower beautifully in the dull months of November and December. Many of the herbaceous plants will now require a little attention in staking each branch separately. Attend to the young growth of climbers before they get crowded, and remove any strong branches that are not likely to produce flowers.

FRUIT GARDEN.

Continue to disbud wall-fruit trees a little at a time and often till there will not be a superfluous shoot left on at the end of the summer: this, with shallow, well-drained borders, is the grand secret of the successful culture of these trees. Look out for curled leaves, and destroy the grub. Thin Apricots, if set too thickly. Stir the surface of the earth among Strawberry plants, and if in a dry state give it a liberal supply of water. Have ready a well-prepared piece of ground for planting out as they are brought from the forcing structures all the pots of forced Strawberries; they will produce strong runners for the next year's forcing, and the crops next year from those left in the ground are generally far superior to the crops grown in the usual way.

STOVE.

Very little fire heat will now be sufficient if the practice of shutting up early in the afternoon is adopted. Attend to training the shoots of twiners as they advance in growth; also, attend to the stopping and training of other plants, and afford the free growing ones plenty of pot room. Proceed with the potting of Orchids as they require it. Do not allow the plants on blocks or in baskets to suffer for want of water; for when the soil in baskets is allowed to get thoroughly dry, the water is apt to run off. Persevere in keeping down insects.

GREENHOUSE AND CONSERVATORY.

Camellias now making their growth require large portions of water daily, if the pots are thoroughly drained. Watch carefully the progress of climbers, see that they are frequently trained, as they soon get out of order. Hybrid Indian Rhododendrons and Chinese Azaleas will now be in great beauty, and every precaution should be taken to preserve the blooms from damp and drip. Supply them liberally with water at the roots, as, during their blooming season, they require large quantities. Many Heaths and hardwooded plants will now be in bloom, or approaching that state, and, therefore, will require careful attention in watering, and abundance of air, bearing in mind the injurious effects produced by currents. Plants out of bloom to be placed where they can enjoy a rest for a short time, as otherwise they generally break weakly when the new growth commences.

PITS AND FRAMES.

Pot off all recently-propagated plants, and see that you have a sufficient stock of everything to plant your beds properly, if not, get in some more cuttings without delay, which will do well to fill up gaps in the summer. The long-continued easterly and north-easterly winds with frosts render the management of bedding stock rather difficult this season; for it is still dangerous to risk even the hardier kinds from under the protection of glass. All that can safely be done, until the weather changes, for

hardening the stock preparatory to its being planted out is to give as much air as the weather will permit without injuring the plants, and to place Calceolarias and the stronger Verbenas in turf-pits, where they can be protected at night, and sheltered from the drying winds. W. KEANE.

DOINGS OF THE LAST WEEK.

KEPT turning over the unoccupied ground in the kitchen garden, turning over the beds in flower garden to pulverise the heavy soil, and getting the heated soil down and the cold soil up. Staked all the Peas that were up and any length, as the ground was nice and dry, and forking the ground slightly among and close to the rows to encourage active growth. Sowed succession crops of Peas and garden Beans, and the first sowing of Kidney Beans and Scarlet Runners out in the open ground. Sowed also French Beans in boxes, to plant out under a little protection. Sowed also a succession of Turnips, and Scarlet and Turnip-rooted Radishes; and of Turnips, now preferring chiefly the American Red-top, for its white colour, and delightful, crisp, sweet flavour. There are several fine yellow Turnips as the Maltese, but there is not one cook in a hundred that will cook them. Watered newly planted trees and shrubs, and Currants, Gooseberries, and young plants of Strawberries, and those turned out of pots in which they had been forced. Hoed the surface between the rows, but not deep, so as to cut up any small seed-weeds, and chiefly to make a loose surface to prevent the ground cracking in the dry, cold weather. Strawberry plants showing very well, and will have a dressing of lime with a little soot, if it can be spared, between the rows, to kill or set a-flitting the whole tribe of snails or slugs before the fruit begins to swell, and thus prevent, if possible, the annoyance when picking an extra fine dish to find that many of the best fruits have had a hole pierced in their sides before you gathered them. Disbudded Peaches and Nectarines, and watered those in pots as required. Tied out and thinned out all the extra shoots in second vinery, and removed extra laterals in first vinery, and nearly finished thinning fruit, and when that is done, will allow more laterals to remain to increase root action, and remove and thin gradually as the fruit approaches perfection. As the fruit is now swelling in the small Vine-pits and the early house, the night temperature averages 60° , the day temperature from 70° to 75° without much sun, and with sun and air early given rising from 75° to 85° , and 90° . In the second vinery where Muscats and others are coming into bloom, we like the night temperature to range from 65° to 70° , but are content even with 60° , if we get a good rise from sun heat during the day. The Muscats generally set well. The house is kept in a medium state as respects atmospheric moisture, and in a very warm day has the floor and stages sprinkled whilst the Vines are in bloom. Extra dryness and extra moisture in the atmosphere are equally prejudicial at that period. In the late vinery, tied up last week, went over it and thinned out a number of extra shoots, and marked those with a piece of matting attached to them that were intended to be fresh leaders and rods for another year. Keep this house just beginning to show fruit at about 50° at night, and plenty of air during the day, as it is coming quite as early as we wish. Filled all the underpart chiefly with Fuchsias, fresh shifted into large pots, and the front, back, and suspended shelves near the glass with Strawberry plants. This house being the only vinery now in which they will do any good except at the front of the house, as even if the fruit should swell, it will neither have fine colour nor good flavour without the direct action of light. The great dependence here is on Keens' Seedling, but Prince of Wales (Ingram's), is showing and setting well; British Queen is also showing well but later; and much the same may be said of Sir Harry, the chief merits of which, in-doors, I always consider to consist rather in the size of the individual fruits than the quantity that can be gathered from a plant, or a row of plants. It also sustains carriage better than Keens', and so do the Prince of Wales, Queen, and others. But for a regular continuous daily supply, to be sent at once from the garden to the table, none I have yet met with is so useful when grown in-doors as Keens'. Took up a number of small plants of Keens' that had been pricked out thickly in a border in autumn, and potted those showing strongly and plunged them in a bed of leaves out of doors, in case they should be needed before the out-door supply should come in. Such plants are very useful at this season for filling a pit, or frame, with or without the assistance

of a little artificial heat. Regulated Cucumber and Melon plants, and in the case of the latter disbudded all incipient shoots not wanted, preferring to have no fruit shown until the plants had obtained strength to set and swell the young fruit when it did show. Of this more next week if I can think about it. Cleaned and swept Mushroom-beds, and gathered large ones to prevent the beds being exhausted. Put up a bed consisting chiefly of old stubble and tree leaves, in a shed out of doors all open in front, making the bed about 15 inches deep, and treading it firmly just to secure a little mild heat, and using the above because I could find no better, and knew it would answer my purpose. On that spread about 2 inches of short straw and fresh horse-droppings, and beat or trod firm. When that bed heats and begins to cool moderately to 80° or 90°, the spawn will be inserted almost on the surface, and be covered with 1 inch of similar droppings, and as soon as practicable be earthed down and covered slightly with dry hay. In such a place we generally have a fine supply in the hot summer months, when the Mushrooms in houses are apt to become thin and eaten by maggots. The open side of the shed faces the west, but trees intercept the sun's rays, and to keep it out more effectually and prevent too great a sweep of air, wattled or thin-strawed hurdles are placed along the sides in front. Thinned out and regulated the shoots in the Fig-house, generally showing plenty of fruit. Here I may note, my White Marseilles is showing few fruit, while one of the small plants obtained from Mr. Rivers is showing fruit at each joint, thus proving so far that there must be two varieties of that fine Fig. The trees being planted in stiffish soil, above a layer of brickbats, and with openings to let out extra water, gave the trees a good watering with water from the farmyard drainage, adding other water to prevent it being too strong. Continued to put in cuttings of Verbenas for the last time, and to turn out those struck, generally in lumps or small potfuls, in soil below calico protection, and to prick off seedling Petunias, *Cineraria maritima*, *Lobelia*, *Calceolarias*, *Chilices*, *Tomatoes*, and other things too numerous to mention, using large pots or boxes for this purpose, filling the pits half full of any rough material and just having some fine soil within 1 inch or 2 inches of the surface. Sowed Balsams for the first time, as it is useless to sow if you cannot find room to grow. It will be time enough to sow in the first week in May, for plants intended to be placed in rich soil in the flower garden.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

TRANSPLANTING TULIPS AFTER BLOOMING.—(L.).—The 1st of May will be too late and too early to remove Tulips; the later in May they are removed the better. But there is no risk in moving them any day; the effect of moving them too early will be smaller bulbs for another year.

NEW LARGE BED (D.).—Your new large bed of bad wet soil, for which no preparation can be made this season for planting it, might puzzle a lord; but a lady would soon turn it to good account, it only as a refuge for the destitute. But another "D." and a "B." would probably make it the best-telling bed in the garden after the following manner:—Line it off in shallow drills 2 feet apart, and drop seeds of *Tropaeolum majus* at 2 feet asunder in the drills; or without drills, put them in at the same distances, like planting winter beans. When the plants covered the surface, he would also, probably, put a row of stout pieces from the tops of pea-takes all round the bed at a yard from the sides: these would stand 3 feet apart, and be just 2 feet only above the surface. Another row of such stakes, but a yard above the surface, he would place along the centre of the bed, in such a way as would make every stake in the centre row stand midway between each two in the first row all round. The shoots would soon run up and cover these stakes completely, and festoon themselves on the natural system. He might assist them to run up, it is true, also incline them to the artificial system of festooning, but that is not here or there; and you might take another turn, and hit on a whole collection of the seeds of all the new Tropaeums, and do them on that plan, and perhaps make an edging of Tom Thumb Tropaeum all round, putting in the seeds 10 inches from the sides, and 10 inches seed from seed, if the seeds were all to be depended on for sprouting. No plants pay better in the worst soil than the Tropaeums, provided always the worst soil is fresh, and has been recently dug, trenched, or knocked about.

BASILLA CORDIFOLIA (O. P.).—There must be some mistake about the plant you received from Philadelphia, as *Basilla cordifolia* is an annual which needs to be reared like ridge cucumbers; the leaves only are of any use, being a kind of bad Spinach not worth growing in England. The French have used it as orach.

ROSEWOOD (A. H. W.).—It is the wood of *Physocalymma floribunda*—a tree about 80 feet high, found in the province of Goyaz, Brazil.

NEW FUCHSIAS (F. M.).—Your list of twenty-nine kinds of new Fuchsias contains only such kinds as have not yet been proved by public competition; none of them, therefore, could with justice be recommended before another, and no one could do so but at random. Selections can only be safely made after public judgment has passed. We recommend all new seedlings which are promising as new plants, not as selections. There is a wide difference between recommending new plants and recommending a selection of new or old plants, which ought to be well understood by the public, to save the purse and the credit of editors. *Cineline* is the only one out of your list that we have yet decided upon as first-rate.

POTATO ONIONS (*Ignoramus*).—These should be divided before being planted.

VINES FAILING (*Bib*).—The leaves falling and shoots dying intimate that there is a failure at the roots. Want of drainage, or bad subsoil, or some other circumstance depriving the Vine of a supply of sap, is the cause of the mischief; but no one can tell without an examination of the roots.

ONOTHERA TARAXICIFOLIA AND MACROCARPA (W. C. W.).—The two *Onotheras* ought to bloom from February-sown seeds after the middle or end of July; but much depends on the kind of summer and the nursing of the seedlings before turning them out.

FLOWER-GARDEN PLAN (*Rector*).—Your planting is very good and choice, save the edging to *Gazania splendens*, which trails like a *Verbena*, and no edging could be safely kept round it, except, perhaps, an edging of *Gazania rigens*, which is a stiff, upright plant, with the same kind of flower.

EMPLOYMENT AT CRYSTAL PALACE (G. & M.).—We do not know that more gardeners are required there, and none would be employed without unexceptionable testimonials.

STUMPS OF TREES ON LAWNS (*A Notice*).—Scarlet Geraniums encircled by *Nummularia* look well; but not knowing the size of the stumps, nor their situation, near or far from the house, we cannot advise you. Send a ground plan, and what you propose planting, and we will tell you what we think.

CUTTINGS OF MONTHLY ROSES (J. T.).—These root well managed just like *verbena* cuttings in the spring and autumn, but take longer time to root. An old Myrtle is an enormous rooter and needs great room; but at this season almost all the ball might be shaken off, and one-third of the tops of the roots be then cut off. Give strong fresh loamy soil, and in July and August it requires abundance of water.

AZALEA AND CAMELLIA CULTURE (A. F. W.).—You would see lately in "Doings for the Week" much that would suit your purpose. Azaleas and Camellias may be treated much the same. As soon as finished blooming, and all the old flowers removed, it is well to try and stimulate fresh growth by extra heat and moisture, so as to get the flower-buds forced early. When the end of the young shoots become hard, they may stand anywhere in the open air, provided they are put in doors before suffering from cold. This assistance now is all the forcing the Camellias will need; but the Azalea-buds being properly set and matured, you may bring them into bloom in winter and spring, just as you like to apply the heat. Perhaps ere long Mr. Fish may meet your wishes by fuller directions, though they chiefly be repetitions of previous papers on such subjects.

CLIMBERS FOR CONSERVATORY ARCHES (H. B.).—It is no easy matter to manage evergreen climbers to cover arches ways, under glass, when they must be grown in pots or boxes. *Teocoma jasminoides* is the best we know, as you care more for a fine green than for flowers; and *lithyospermum jasminoides* is about as good a plant as the other and blooms freely. Put them in the largest boxes you can manage, with strong loamy soil, and a perfect drainage, as in summer you will have to water often. When three flower-beds, or thirty, or three hundred, are seen from one end in a line, there need not be a match pair in the whole, and a bed of *Tropaeolum elegans* must never have an edging of anything; it would kill the edging plants. The rest of your proposals are very excellent.

HARBY ORCHIDS AND FERNS (A. C. W. P.).—The information has been printed in our columns, and a separate work on the subject by Mr. Appleby, will be published at our office in a few days.

SHADING ANNUAL SEEDS SOWN, &c. (*An Old Subscriber*).—All annual seeds should be shaded under glass until the seedlings are up; it saves watering and they come quicker. Sowing on a border in patches, and a pot turned over each patch, is a good plan. After the seedlings appear, shading does more harm than good, except in the middle of hot days. We never mix manures with them. No watering is necessary to Crocuses, Irises, early Tulips, or bedded Hyacinths, after the leaves begin to turn yellow at the bottom. The best plain-leaved Scarlet Geranium for bedding, is the Crystal Palace; and of the horse-shoe-leaved, Baron Hugel. Punch is kept dwarf and level in growth, by merely making late autumn cuttings of it.

NAME OF ORCHID (A. Z.).—It could not be told from such a fragment. There is no novelty in your treatment of the Nymphæa; and speculation about the Cucumber would be waste of time and space.

NAMES OF INSECTS (J. M.).—The insects which have devoured your rows of Peas are the striped Weevil, *Sitona lineata*. Strew soot thickly along the rows, having previously watered them. Pulverised unslaked lime spread half an inch thick upon the ground has also been suggested as a remedy.—W.

NAMES OF PLANTS (S. Dero).—No. 1, *Alliaria officinalis*, commonly called Sauce Alone and Jack by the Heds.; No. 2, *Stellaria holostea*, the Greater Stitchwort. (*Trisulca*).—Your Fern is *Blechnum spicant*, var. *imbricatum* (R. F. S.).—The leaves are like those of *Hoya carnea*.

FLOWER SHOWS FOR 1861.

MAY 18th. CRYSTAL PALACE. (Plants, Cut Flowers, and Fruit). Sec., W. Houghton.

JUNE 5th and 6th. ROYAL HORTICULTURAL SOCIETY. (Plants and Fruit). Garden Superintendent, G. Eyles.

JUNE 12th and 13th. YORK. Sec., J. Wilson.

JUNE 19th and 20th. BRIGHTON AND SUSSEX FLORICULTURAL AND HORTICULTURAL SOCIETY. Sec., E. Carpenter.

JULY 6th. CRYSTAL PALACE. (Rose Show). Sec., W. Houghton.

JULY 10th. ROYAL HORTICULTURAL SOCIETY. (Rose Show). Garden Superintendent, G. Eyles.

SEPTEMBER 4th and 5th. CRYSTAL PALACE. (Dahlias, Cut Flowers of other descriptions, and Fruit). *Sec.*, W. Houghton.
 SEPTEMBER 11th. ROYAL HORTICULTURAL SOCIETY. (Dahlias and other Cut Flowers). *Garden Superintendent*, G. Eyles.
 SEPTEMBER 18th and 19th. BRIGHTON AND SUSSEX. *Sec.*, E. CARPENTER.
 NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums). *Garden Superintendent*, G. Eyles.
 NOVEMBER 12th and 13th. STOKES NEWINGTON CHRYSANTHEMUM SOCIETY. *Sec.*, W. T. Howe.
 NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show). *Sec.*, W. Houghton.

N.B.—*Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.*

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

MAY 21st, 22nd, and 23rd. CHESTERFIELD AND SCARSDALE. *Hon. Sec.*, Mr. Thos. P. Wood, jun., Boythorpe House, near Chesterfield. Entries close May 1st.
 MAY 22nd and 23rd. BEVERLEY. *Hon. Sec.*, H. Adams. Entries close May 4th.
 JUNE 4th, 5th, and 6th. BATH AND WEST OF ENGLAND. *Steward*, S. Pitman, Esq. Entries close May 4th.
 JUNE 19th, 20th, and 21st. COALBROOKDALE. *Secs.*, J. B. Chune, and Henry Boycroft, Coalbrookdale.
 JUNE 25th. ESSEX. *Sec.*, W. R. Emson, Slough House, Halstead, Essex.
 JUNE 25th. DRIFFIELD. *Sec.*, Mr. R. Davison. Entries close JUNE 22nd.
 JUNE 28th and 29th. TAUNTON. *Sec.*, Mr. Charles Ballance. Entries close JUNE 14th.
 JULY 3rd, 4th, and 5th. BLACKPOOL AND WEST LANCASHIRE. *Sec.*, Mr. E. Fowler, jun., Market Street, Blackpool. Entries close JUNE 30th.
 AUGUST 26th, 27th, 28th, and 29th. CRYSTAL PALACE SUMMER SHOW. *Sec.*, W. Houghton.
 SEPTEMBER 3rd. POCKLINGTON (Yorkshire). *Sec.*, Mr. Thomas Grant. Entries close AUGUST 26th.
 SEPTEMBER 24th. BRIDGNORTH. *Sec.*, R. Taylor, Bridgnorth.
 DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. *Sec.*, Mr. J. B. Lythall, 14, Temple Street. Entries close NOVEMBER 1st.
 DECEMBER 11th, 12th, 13th, and 14th. CRYSTAL PALACE WINTER SHOW. *Sec.*, W. Houghton.
 N.B.—*Secretaries will oblige us by sending early copies of their lists.*

PRICES OF POULTRY IN LONDON.

THE dearth of poultry in Leadenhall Market still continues, and with the dearth the high prices. The supply at this season of the year is as important to those who deal in it as cotton is to Lancashire, and to Manchester in particular. It is the same with both parties. So long as the supply is regular, prices tolerably easy, and things smooth, it is hardly worth asking whence the goods come; but when there is the prospect of losing the article on which the trade depends, there is eager inquiry for a new market, or for a substitute; and vows are made, that for the future they will not expose themselves and their trade to the chance of suspension, nor to the fluctuations of one market.

We will leave cotton to fight its own battles, but we must continue our remarks and instructions on market and its supply. Since we last wrote the quantity sent to market has diminished rather than otherwise: as a natural consequence prices have been more than maintained. We have always fancied that unusually high prices in a public market are like the fiery cross of former days in Scotland—the message is heard and understood by all whom it concerns, and the summons is attended to.

In Kent, Surrey, and Sussex, the electric telegraph works from Leadenhall Market to the different towns on market days; and those two hale, hearty men who are squabbling, almost fighting, over that basket of fowls, are roused to their state of excitement by the news sent from London of that morning's market, and an increase of price. Perhaps our readers have no idea of a poultry market at this season of the year when it is scarce. There is none entirely devoted to fowls and chickens; but as the cottagers and small farmers go with other produce, so they take their poultry; and the higgler who collect, attend for the purpose of buying it.

When the demand for fowls is as great as it is now, you will find the first people at market will be two or three men who will arrive in skeleton carts filled with crates for live fowls. When they have put up their horses they walk uneasily about the market place, watching those roads by which fowls mostly arrive. If a well-known face is seen, one who has the reputation of feeding good ones is seen, or if a crate is seen at the back of a cart, all three start at once at a run; each wants a promise of the refusal of the lot—that is, the offer of them at a certain price. We do not believe those who talk of "picking up" things, or, to speak plainly, those who do not buy bargains, but who are continually trying to persuade the world that their superior knowledge has enabled them to buy things at a price far below

their real value. Our experience is, that as a rule, sellers know quite as much as buyers, and that it is next to impossible to buy 5s. worth of anything with 2s. 6d. The owner of the fowls is aware of their value, and refuses to commit himself in any way. He will pitch his wares in the market. He does so, and often a bigger will take each end of the crate, and thus without handling they will bid against each other till one or the other gives up, and the fortunate purchaser has carried his point at a price that renders profit impossible. The first time this happens, it acts like the "fiery cross." Far and near it is spread that such a one made such a price of his fowls; every one who attends that market becomes the "colporteur" of the news, and many a chicken is crammed that day for the first time in consequence.

It also acts as a summons, every fowl that is nearly ready for killing is taken at once to market and finds an easy sale at a large price. But there are times like the present, when those who are habitual senders cannot supply a sufficient quantity, and then there should be help from the class we wish to interest in it. We wish amateurs to be providers; we wish ladies and gentlemen to take trouble with marketable poultry as they do with honey, fruit, or cattle. No man, whatever his position, hesitates to sell surplus fruit; a nobleman will have an annual sale of fat stock, why may not a lady in the country sell some spring chickens? Too many imagine that it is useless to undertake it unless they can send dozens at a time. They would soon see their mistake if they attended the markets. The higgler who collects two dozen does so very often from five or six different people. They bring that which they have—one four, another three, and so on, and these often take back the figures we quote, and which are sometimes called in question.

(To be continued.)

ENDURING INFLUENCE OF THE MALE—CHARACTERISTICS OF DORKINGS.

SUPPOSING a Spanish cock escapes for half an hour or so with a Dorking hen, how many eggs are laid before the cross shows itself? and does it affect one egg or the whole set?

How may I distinguish a coloured Dorking cock from a Silver Grey Dorking cock?—A NEW SUBSCRIBER.

[If the Dorking hen has been running without a cock, then the probability, but not the certainty, is that the eggs she will lay are all spoiled. If she has been running with a Dorking cock previously, we do not think the accident will have any result.

A Silver Grey Dorking cock *must* have a black breast and tail, *white* hackle and saddle, and *must not* have any red or chestnut feathers. An ordinary Dorking has no colour, and may indulge in any vagaries as to tint or hue of feather, but he *must* have white legs.]

PROFITABLE POULTRY KEEPING.—No. 3.

(Continued from page 70.)

MUCH has been said and written relative to the soil on which hens and their chickens best thrive. There can be no question that sand or gravel is to be preferred; but let none despair should their lot be cast on a stiff clay, for it was on such that the results given in my last were obtained.

And now for the life of a chicken from the nest to the salesman. This I will endeavour to exemplify by a few simple rules, which will require the exercise of common sense only to bring matters to a successful issue.

KEEPING OF EGGS FOR SITTING.—Eggs intended to be used for sitting should never be laid on their sides, but retained in an upright position, with the narrow end downwards. This is readily managed by putting a few inches of moss into a shallow box, and placing the eggs therein.

SITTING THE HENS.—In spring and summer put the "magic number," thirteen eggs, under the hens; but in autumn and winter do not exceed nine or ten; and care must be taken that the eggs are all of one day's laying if possible. More depends upon attention to this than may at first sight appear. It is well to sit more than one hen on the same day, should you be so fortunate as to have more than one hen broody. This simplifies after-management, by making one hen nurse two hatches; and allows the others to recover strength and come into laying again sooner. If possible, sit on the ground; but should the

hen have chosen her nest do not disturb her, unless the situation be manifestly disadvantageous, and place a large turf under her.

HATCHING TIME.—If attention was given at sitting time to use none but eggs of an equal age, the chicks will, as a rule, break the shell within a few hours of each other. New laid eggs will be hatched under the twenty-one days; fresh eggs (those laid three days or a week before sitting), will take the entire time; and stale (though not unprofitable eggs), I have known take from twenty-two to twenty-four days. Chicks from the latter, are generally not so lively and do scarcely so well; but I have rarely noticed any difference between those from new laid, and those from fresh eggs as to their after-thriving, each coming as early to profit as the other. It is a most reprehensible practice to remove the chickens from the nest as they are hatched; it irritates the parent bird, and I think it is positively essential to the well-being of the young ones to be left with the hen. I cannot lay too great stress on this point, for it is the fruitful source of disappointment and loss. When all are free from the shell, entice the hen off the nest by throwing down some food, and then remove the shells. Do not afterwards disturb her for twelve hours or so. She knows when her young are strong enough to move about, so leave this to her.—**LEIGHTON.**

(To be continued.)

LEG-WEAKNESS IN A COCKEREL.

I HAVE a Dorking cockerel eleven months old which cannot stand to eat its food. Its legs tremble very much when standing, and the claws are now getting drawn backward. It has been in the same state since being a chicken. I attribute the whole to entire weakness. The bird eats greedily, and appears in every other shape quite healthy—the comb being red, and stands erect. I fear his walk has not been good, being short of food, and under-walked with other cocks.—**R. P. B.**

[It may be that the bird has been badly walked, and that would account for the weakness; but if that were the only cause, better feeding would remedy it. We should be disposed to attribute it more to a bad flooring of the roosting-house. Stones, bricks, and boards would all cause paralysis. If this be the reason, the cock is in the same state as a man, who, having slept in a damp bed, recovers his health, but loses the use of his limbs. Whether this be the cause or not, a bird of his weight (10 lbs.) is worth saving at the cost of some trouble. Feed him frequently a little at a time on stale bread soaked in strong beer; give him boiled egg chopped fine, and if that does not succeed, give him some raw beef.]

LIGURIAN BEES IN SCOTLAND.

I HAVE just received the following letter from a correspondent, to whom I sent the only Ligurian queen which I was able to part with last season. I have again commenced rearing Ligurian queens, and have every hope of being enabled to supply all who apply to me with as many as they may require.—**A DEVONSHIRE BEE-KEEPER.**

"Now that the rigours of a more than ordinarily severe winter and also somewhat untoward spring may be considered over, I may now be able to give you a pretty correct idea of the state of my Ligurian-hive, which I got from you last season. I have every reason to be satisfied with its present appearance. They are a strong hive and breeding rapidly for this season of the year, and working very vigorously whenever the weather will admit of their being out. I see that they are generally at work an hour earlier in the morning than the others, which will be an advantage in the honey-gathering season; and, indeed, in every respect they seem perfectly adapted for our northern Scotch climate. They have been breeding young bees since the beginning of March, but, of course, now producing them in a greater ratio. I have been feeding with Glasgow peameal for fully a fortnight, but have withheld it as soon as the blossom has got out on the berry bushes, &c.

"It has fared better with my apiary than with most of my neighbours, as my stock appear all in working order, with the exception of one which has lost its queen, which I hope to be able to replace if the weather proves favourable. However, I may mention that I shall not be greatly disappointed if I should fail in this case, as they are not very strong of bees.

"This winter has proved very disastrous on bees throughout

this county (Berwickshire); as I am decidedly within the mark when I say, that fully two-thirds of the bees have died throughout the county: in several instances, only one is alive out of a stock of eight or ten.—**J. S.**"

BEE-HIVES AND THEIR APPURTENANCES.

(Continued from page 72.)

MOVEABLE FRAME-HIVES are only different as regards the frames. The mode of fitting may be worth mentioning. I carry the notch on the bar in as far back and front as to allow the top of the end pieces to be sprigged thereon (which saves clamps). They are held together below by a narrow slip of wood, or, as good, a stout wire. Having the bottoms of the frames as broad as the bars impedes the ventilation of the hive.

ADAPTER-HIVE SYSTEM.—A common fault of many depriving-hives is a *fixed breeding space*, possibly too large at the outset, and too small afterwards. Take for example the absurdity of Nutt in his collateral-hives, devoting a space of only 1 foot square by 9 inches deep, as his pavilion of Nature for a *non-swarming* colony, expected to fill two end-boxes of pure comb of similar dimensions. No ventilation could possibly keep a prolific queen from either breeding in the end-boxes, or swarming in disgust. He must have made but a slight acquaintance with bees who has not observed their contrivances, if I may use the word, the diversities in the breeding powers of queens, the unequal size of swarms, the variableness of our seasons and climate no doubt materially affecting the whole. The great desideratum, then, to the practical bee-keeper is, the possession of a hive at a moderate outlay, that in his experienced hands can be adapted to meet the peculiarities of every case and season. This leads me to narrate some observations how storing of honey in the super may be promoted, and the breeding of the queen encouraged by a change of system I have latterly adopted, which, for want of a better term, may be styled "adapting." From the experience I have had of strong colonies wrought on the storifying plan, I have noticed in some of my Stewarton-hives—for instance, when the breeding-boxes had attained a height of 18 inches or 2 feet, a disinclination in the tired honey gatherers to elbow their way up such an altitude to the super, and rather avail themselves of the handy vacated brood-cells in, say, an upper breeding-box, thereby unnecessarily protracting the completion of the super. This temptation is also enhanced by the predilection of the queen to take up her quarters in the box containing the greatest quantity of brood, to the partial neglect of the others, besides a general shyness to pass from box to box. Take, for instance, a set of three breeding-boxes. At the end of the season, in addition to the super, the upper will be found filled with sealed honey, a fair supply with the queen, and the bulk of the bees in the centre, and little but empty combs with some bees in the lower. No doubt a partial deprivation might be made from the upper box, still as the comb had been bred in, it would only be valuable as run honey. To obviate these evils I have devised a means which, so far as I have acted on it, has given me satisfaction. Suppose a good prime swarm hived in any of the boxes already described (the octagon is preferable), and after a few days another in a box of like dimensions, placed under the first the evening of swarming. All the slides drawn and an amicable junction effected, admission being given at the same time to the super by drawing each end-slide only of upper box. The following morning the lower box to be withdrawn (by which time the bees will, in all probability, have ascended to the super), and in lieu of it substitute an eke one-half the depth of the box, having windows of similar length, and one-half the depth, handles and entrance the same, with four little buttons or bars to prevent displacement. Across and flush with the top of the eke, place a half-inch-square support to the combs an inch into a half-inch cut in each end to receive it. The box-entrance will, of course, be closed, the bees passing out through the eke. The bee-keeper to use his discretion in supplying another eke so soon as the exigencies of the case imperatively demand, and so on to the end of the season. Should both swarms be large, and particularly if the first has had a week or more start, filling the box a considerable way with comb, it may be safer to prevent brood in the super, placing two ekes at first in lieu of the second box, or better, one eke the full depth of the box. A good deal must be left to the judgment of the apiarian in handling the hive to meet various peculiarities as already hinted at. The advantages of this system are as follows:—When a colony is naded in the usual way, a *large*

addition is at once made to the space, larger, perhaps (unless the weather be all the more favourable), than their immediate wants demand. Bees generally show a hesitancy in commencing in a new compartment (sometimes rather swarm than do so), except the weather be hot and the hive unusually crowded. When once possession has been taken, a number of the gatherers are called off work to cluster together so as to raise the necessary heat for comb-building. By the system I have adopted, the additional space is supplied more gradually and less perceptibly to the bees, the comb-builders carry on their work continuously down, more in keeping with their habits, and the order of operations thereby suffers no change. The hive is thus divided into two compartments only, a breeding and a storing, the queen having unrestricted range over a much larger area of comb, will have the effect of stimulating her breeding powers, and the space occupied by brood will be gradually extended downwards as the combs are lengthened. So soon as young bees leave their cells she is at hand to re-occupy with eggs. The honey gatherers are less tempted with vacant cells to stop short of the super, where a greater deposit of honey in pure comb more rapidly stored, is the result. The body or breeding space being thus appropriated in a great degree to its intended use, and the bulk of the store removed in supers, the hive will not attain an undue altitude as with storifying-boxes. The saving in employing ekes instead of boxes is apparent. By severing the comb with a strong thread or a comb-knife, the hive can be reduced at any eke, a spare one placed below to keep the comb off the board, the separated portions made available for another colony, by simply screwing on a board above; a partial deprivation could also be made from the top box in the same manner, should the weight justify the proceeding, or be made useful in any way almost as easily as storifying-boxes, the comb remaining securely attached to the cross supports.

COLLATERAL-HIVES.—Suppose we invert a common straw or any hive, where do we invariably find the honey stored? The merest novice is at once prepared to answer—The upper portion of all, and the end combs exclusively, are devoted to this purpose. Additional storing space is, therefore, appropriately given above by supering, as in the storifying, and at the sides, as in the collateral system. The nearest approach to a complete hive, strictly copying the procedure of the bees, is one combining in a measure both, such as I am about to describe, offering equal facilities for either. Again, What proportion should the space set aside for brood bear to that for store, taking the natural procedure of the bee as our criterion? Not, certainly, Nutt's of one of brood to two of store (exclusive of bell-glasses); the reverse would be much nearer the truth: hence the disappointment by swarming, queens breeding in end-boxes, as previously mentioned, and the blasted expectations of the possessors of his hives regarding the great harvesting prospects held out by that author, with, I am afraid, the too great partiality of parental fondness. Whether it be that our cold, variable, northern climate is less suited, causing the bees more readily to abandon the end-boxes than in the more genial south, I never yet met a Scotch bee-keeper who spoke favourably of the system.

Some years ago I constructed collateral-hives, saw and endeavoured to remedy their defects; but never yet tested them so fully, or pitted them against the storifiers. Under similar circumstances, to pass a decided judgment, I will describe for the benefit of such of your readers as have a fondness for the system what I have done in the way of improvement, and should they think of adopting my hive with the advantage of a superior climate, it will afford me pleasure to hear of their success in these pages. Adopting Nutt's as the basis, which consisted of three

boxes, a central or pavilion as he styled it, 1 foot square, by 9 inches deep, communicating with two end-boxes of like dimensions, by a half-inch way at bottom, and another perpendicular one carried up the centre of each end with dividing-tins and other lesser details. The main defect of this hive is a difficulty to induce the bees to commence operations in the side boxes, as they will often swarm in preference. My first expedient was to close the central entrance, and open the one in the side-box, thus forcing them to pass through it, affording at the same time a fair opportunity of inspecting the "shop to let." This if resorted to in time, and the weather unfavourable for swarming, may have the desired effect; but should they have previously determined to go, no amount of coaxing will force them to remain.

I then met this defect by the original notion and effectual plan of fitting sliding ends to all the boxes, thereby saving the dividing-tins, &c., proceeding as follows:—Suppose the pavilion crowded, I carefully draw out the end of the central and side-box, thereby throwing both into one; it is at once looked on by the bees as but an ante-drawing-room after all, and they extend themselves into it, and commence work on the guide-combed bars. When once fairly established therein and comb appearing, I as carefully slide in the ends to within half an inch of the front, this serves in lieu of Nutt's central half-inch-way, and I think a decided improvement, for this reason:—Any one looking through a back window must have noticed the partiality of the bees on entering, to turn up on and run along the inner front of the hive. The two boxes being placed exactly parallel, they without obstruction pass along from the front of the one to the other. Whereas by Nutt's mode they were obliged to go round to the central-end opening; part of the heat would also escape through this opening into the ends; by the other a greater quantity of pure air will seek its way from the entrance to the sides, and the breeding central portion be kept more compact.

The first set of collaterals I constructed were of Nutt's proportions. Finding the side-boxes too large to be fully completed, I halved their depth, substituting two boxes $4\frac{1}{2}$ inches instead of one 9 inches deep for each side, with the further improvement of six $1\frac{1}{2}$ -inch bars on the side, and seven $1\frac{1}{2}$ -inch on the central-box. I was thereby enabled on finding the latter too small to nadir with one of the side and super with the other, working the remaining pair collaterally. Being fully convinced subsequently of the disproportionate smallness of Nutt's central-box, I have increased the size to $15\frac{1}{2}$ inches between the ends, and $1\frac{1}{2}$ inches back to front, both inside measure, retaining the nine-inch depth; the top formed of eight bars (six narrow and two broad); window of proportional depth and entrance, all as previously described for the square wooden hives. The way I manage the sliding end is so simple that any amateur can easily apply it, and construct from the full description a set for himself. When the front and back boards ($15\frac{1}{2}$ inches by 9 inches), are all neatly dressed and squared, the ends made particularly smooth with the hand-plane, an entrance and space cut for the window-glass, take two bars (bar-and-slide hive), 16 inches long, notch out 1 inch from the under side of each end as if intended to lay on the top, place the two boards on a flat, smooth surface, and after fitting a slide into the lower groove of each bar attach the bars to the back and front as low down as will allow the slide to work easily. This forms my half-inch-way at bottom. When the bars have been firmly screwed the boards will stand exactly 11 inches apart, the top bars can then be placed and screwed to keep all firm. Prepare the sliding end of one-quarter-inch dressed, a check top and bottom front edge, the latter working into the upper groove-end bar, the former in a bit of reversed slide sprigged on above. There is a slip of wood nailed on the front end to prevent the end sliding too far, and a little narrow button of wood on the inside top to prevent it slipping inwards. It projects an inch behind for a catch to draw by, and is roughened on the inner side as before mentioned. The wood dressed so thin must be well seasoned to prevent warping. To further guard against this, I generally fix with small screws when the end-boxes are not in use. The inner ends of the side-boxes are to match, and precisely similar, their outer ends of three-quarter stuff nailed fixtures, of course. They should not exceed (what-ever less), 10 inches from end to end, this allows room for five $1\frac{1}{2}$ -inch bars, they can either be of a similar depth or in pairs. Should they be anything neatly constructed when the ends are drawn, the inside of the roof, centre, and side will be exactly on a like without obstruction, save the little checking-button already mentioned, and the nearer the end-bar in the one the other

the better. A full-sized Stewarton-super can be placed on the top of the central, admitting through each end-opening only.

On the shelf where this hive stands, there is cut out below the centre of each end-box, a portion 9 inches by $5\frac{1}{2}$ inches, lengthways. These pieces work downwards with a pair of small brass hinges, kept up when at rest with a button bolt fitted on below; over this space perforated zinc is nailed. When the heat of the weather or the state of the hive calls for ventilation, it is afforded by means of these little falling trap-doors. A similar piece—say 10 inches by $5\frac{1}{2}$ inches, placed the other way, under the central-box, with a knob behind pulls out as a drawer to admit the earthenware feeding-trough 9 inches by $5\frac{1}{2}$ inches.

I never found ventilation easily effectible or useful, except below; any benefit that way from tubes as in bell-glasses is chimerical, the first act of the bees being to stop up the perforations; not so below. In some of my roof-hives I have found brood extend to nearly the edge of the zinc, all above and forward from it entirely free.

The advantages of my collateral-hive as now explained, must be apparent, from the facility with which the bees can be admitted into the side-boxes and supers simultaneously. The apiarian has a good opportunity of testing their partiality for either mode at one and the same time, the whole being so much in keeping with their habits, their energies are fully tasked, rewarding during a favourable season, with an abundant honey harvest. I do hope more than one of your southern apiarian readers may people this hive with a couple of prime swarms in the coming season, and report progress.

OBSERVATORY-HIVES.—It having been proved that bees work equally well in light as in darkness, the smoothness, closeness, and coldness of the glass unfit it for taking the place of wood for general use; and their susceptibility of being influenced by all the variations of light, must, of course, cause an increased consumption of store, and is prejudicial to their accustomed dormancy. Still a single observatory may be allowable as a curiosity placed in a staircase window—for instance, fronting the back or gable of a house. In such a situation, from the constant stir of busy life within, it is an object which never fails to attract attention long after the beauties of the most graceful piece of statuary palls upon the sight. I have one exactly such as I have described, for my central collateral-hive, with this difference, that there are placed in front two large thick panes of glass, 13 inches by 7 inches, the inner sunk flush with the frame, the outer in a rabbit, leaving a half-inch space between, the same in back. Finding it close, to promote ventilation, in room of the slides, slips of fine India matting tacked to the under side of a portion of the slide to draw by wire is introduced—this answered nicely—a six-inch thermometer is behind. This hive stood exposed to the full light all the winter, in a staircase window, north aspect. At the commencement of the long frost, on bringing the top covering over the front, they set up such a roar of displeasure at being deprived of their accustomed light, that I withdrew it. The thermometer indicated 25° of frost on the morning of the 24th December (as previously reported); yet, notwithstanding, the bees came through in good order.

Having already dilated on bee-hives with a diffuseness sufficient to lay the foundation of a new bee manual, or subject the writer to the suspicion of harbouring a latent wish to be assumed as inventive partner in Messrs. Neighbour & Son's High Holborn concern, I must reserve till a future Number some remarks on what may be termed their appurtenances.—A RENEWABLE BEE-KEEPER.

(To be continued.)

IRON PIGEON'S NEST.—At the meeting of the Sheffield Literary and Philosophical Society, on April 9th, Mr. Stirling Howard exhibited some horseshoe nails as a sample of two gallons, by measure, of the materials which a number of Pigeons had carried from a blacksmith's shop, and used to make their nests. The facts, as communicated by Mr. E. S. Howard, of Woodside, are briefly these:—"Over one end of the blacksmith's shop is a rude loft, in which are a number of boxes, the domiciles of the Pigeons. The nails, which were taken from canvass bags and other receptacles, are of the ordinary horseshoe kind, of various sizes, some new, others old and crooked. They were, however, laid with some regard to comfort, inasmuch as the points were not allowed to project upwards, but without the admixture of softer materials. This is the more singular, as there is abundance

of straw, shavings, &c., in the neighbourhood. On these 'iron beds' the birds had laid their eggs, which were just ready for hatching when the discovery was made of the use to which the nails were applied. The nails when removed filled a watering-can holding about two gallons, one of the nests containing more than a stone weight. The eggs were destroyed. The Pigeons are of the ordinary kind, but some of them have a cross between the 'Carriers.'"

MILCH GOAT.

FEED them as you would a cow or sheep; milk them at regular times, and strip them dry. They will eat almost any kind of food. Mine was a common Irish Goat, cost 21s., and gave three pints of milk at a meal. Tie them up while milking, and milk from behind the leg. They are subject to lice: a little oil rubbed on the back is all that is required to remove the vermin.—W. S.

GOLD AND SILVER FISH DISEASED.

I THINK "J. B." will find no remedy for the slime upon gold and silver fish, but that of catching them and wiping them carefully (so as not to injure the scales) with a dry, clean, soft cloth. I have found this an excellent remedy when mine have been similarly affected.—GEORGE M. BURTON, Southtown, Larnmouth.

"**THE** fishes with hard skins have, however, one advantage over the soft-skinned fishes, to a greater or less degree—they are not so much troubled with parasitic animals adhering on them. To sickly fish do these parasites principally adhere, just as the bill-stickers in London select a tumble-down house, or else premises in Chancery, to stick their paper parasites, in the shape of advertisements, upon. At Teddington Lock I caught one day, this year, three barbel. I observed that the bellies of these fish were covered with little, round red spots, as though they had been pricked with a needle. I could not understand what these spots were till I caught the third barbel; on to its belly was still adhering a little leech-like beast, that curled himself into a ball when touched, like a woodlouse. With some difficulty I got him off the barbel's belly, and in the place where he had been sucking was one of these little round red spots. The mystery was thus fully cleared up: this parasite had an amazingly sharp pair of nippers, wherewith to pierce and hold on to the barbel's thick skin.

"When fishing at the weir, at Thorney Broad fishery, near West Drayton, in the month of May, a gentleman who was angling above me cried out, 'Look out, there is a great fish coming down the weir!' and sure enough there was a fish coming down in the rapid stream, tail foremost as fast as it could. I just managed to catch him with the landing-net, and found that he was a large roach, weighing $1\frac{1}{2}$ lb. The poor fish had been wounded in the back, probably by a punt-pole, and was in a bad way. It was quite covered with the same kind of parasites that I found on the dead polling bait, so that these little creatures perform in the water the same office that the flies, by means of the maggots, do on land: they devour the offensive animal matter which would otherwise pollute all around.

"The gold fish in the round pond at Hampton Court are also much troubled with a parasitic fungus, which grows upon them; but I never had an opportunity of examining one out of the water.

"Mr. Hall tells me that his fish are much troubled with this fungus. Occasionally they are attacked with a disease of the eye, causing it to bulge out like a small bladder, and sometimes the scales to stand up. The most fatal complaint they have is a sort of ulceration, which takes place on the body on which this vegetation occurs, and shortly covers the fish; after which very few recover. This is, doubtless, a vegetable fungus. Near Hammersmith there are several floodgates communicating with the Thames, round which the roach and dace collect; these fish are covered with this parasitic fungus. It ultimately causes the death of many of them, as it becomes adherent to the gill substance, and prevents their breathing."

In answer to "J. B." I send you the above extract, from "Buckland's Curiosities of Natural History." I cannot send a personal remedy; but I surmise the Thames water to be at the

bottom of the mischief. I myself have observed the diseased state of the fish in the tank at Hampton Court Gardens, which must nearly resemble "J. B.'s;" and just possibly it may be supplied with the Thames water also, in which, were I a fish, it would be difficult for me to maintain a healthy state of existence. It would be well if "J. B." could supply his tank from some other source.—UPWARDS AND ONWARDS.

THE CANARY AND THE BRITISH FINCHES. THE CHAFFINCH.

(Continued from page 71.)

THE French and Belgians are great fanciers of the Chaffinch, and highly prize its song. They keep them in small wooden cages, having only wire at one end, where it is slightly bowed to contain the water. The birds, after being caught, and as soon as meat is off, are deprived of the sight of one eye, and when accustomed to find their food and water the sight of the other is also destroyed by means of a heated needle. These poor blind captives being less easily frightened sing very much; but I abhor the cruelty, and detest the sight of these miserable-looking prisoners in their little dark cells.

The old birds when taken are often very shy, and do not sing the first season. Nestlings when reared by hand are very familiar, and may be taught any of the approved strains; they also vary their song more, but, to my fancy, are less bold and original in execution than old-caught birds. The best Chaffinch I ever remember hearing was one I had at St. Pierre les Calais in 1844, and which was captured in rather a strange manner. A pair had commenced building in an apple tree near the house, and while the servants were at dinner the pair flew into the kitchen—one alighting on the nursemaid's head and the other in her soup, when she grasped one in each hand, and brought them to me. I placed them in a cage, but the cock did not sing that season, and in the autumn I let the hen fly. The next year the cock was kept in a room with many other birds, but I did not notice his singing. The third spring, however, he broke forth in the most delightful rolling melody I ever heard in the way of bird music. He had a large cage to himself, and he continued in full song all the spring and summer; he would repeat and vary his song several times in succession without stopping, pealing forth his lay in a full clear tone. At the end of the first limb he would drop his voice into a murmuring warble, and then again pour forth his song with redoubled energy.

I have reared several nestlings that proved fine singers, and added snatches of other birds' songs to theirs; but none sang so bold and clear as the old Calais bird.

Dr. J. M. Bechstein, the German writer on birds, who was himself a great fancier, has described twelve songs of the Chaffinch as noticed by fanciers in that country. So great is the fashion for these birds among the Thuringian cutlers, that they will sometimes subsist for a fortnight on bread and water in order to purchase a good song bird; and examples have been known of persons going from Ruhl to the Hartz mountains to catch a good songster, as well as of a cow having been given for a first-rate singer; hence the German proverb, "The Chaffinch is worth a cow."

The favourite song is termed the bridegroom's song and runs—"Fink, fink, fink, horst du, willst du, mit dem, Brautigam zierem." In Saxony, particularly in Erzgebirge and Vogtland, the "Reitzug" cavalier's song is preferred.

The wine song, or "Fritz, fritz, fritz, wilt an mit zum Weingehn," is also a great favourite in Ruhl. Several others, as the goodyear and the double song are mentioned, but the above are, I trust, sufficient to illustrate the German reading of Chaffinches' songs. In conclusion of this matter, I will make one more extract. "When a bird only sings one of these songs so is he the more prized, the slower, more distinctly, and deeper his singing; and still more admired if at the end of each song the bird calls 'Pink,' which the amateurs designate the amen."

Pied and even white Chaffinches have been recorded as being met with, but very rarely.

M. Hervieux mentions them as one of the birds that will breed with the Canary. Dr. Bechstein says, "It is an acknowledged fact, that they will breed with the Canary, and that they have paired with the Greenfinch and Yellowhammer." I myself had a Chaffinch raised from the nest that paired with a hen Canary. The courtship was a very rough one, the cock often dashing after his mate, catching her by the crown of the head and holding

her thus suspended. The hen, however, unfortunately proved barren, and I could not prevail on the Chaffinch to take another mate. A Chaffinch is recorded to have lived in confinement twenty-four years.

In summer and autumn the young branchers and old birds are caught in clap-nets when on flight. In winter, when they draw near to the houses, or congregate in the farmyards, I have caught them in small wooden traps made like a box of old weather-stained board, baited with seeds buried in the earth level with the ground, and set like boys do the common brick traps. The Chaffinch is a jealous bird, and in spring each male takes a beat which he claims as his hunting-ground, and drives all others off. This habit has been taken advantage of by bird fanciers to capture the cock when in song at the commencement of the breeding season; to effect which it is necessary to be provided with a song bird as a decoy. These birds are moulted off early like the Linnet, in stop-boxes. A glazed frame in which two or more Chaffinches are enclosed, each in a separate back cage, and thus kept for a time in an equitable temperature, and fed or rather fattened on an extra allowance of hempseed, the moulting is advanced and the birds come earlier into song than they otherwise would. The trapper is also provided with a stuffed Chaffinch so arranged that by means of sharpened wire it can be stuck against a tree; and in the same way a twig besmeared with birdlime is stuck above the stuffed bird or "stale;" the call bird being placed below, the operator hearing a bird whose song pleases him, arranges his decoy in a convenient place and retires a short distance. The birds begin to sing against each other, and the wild male enraged at the presumption of the call bird for singing in his domain, and mistaking the stale for the intruder, dashes down at it and becomes entangled by the limed twig. A somewhat similar arrangement is practised by the German fanciers, a forked stick attached to the back or tail of a live bird which is placed near the wild songster, and he dashing down to attack and drive him off is detained by the birdlime, or a braced bird is pegged beneath the tree, and limed twigs are so arranged round it as to capture the wild one when he charges the decoy.—B. P. BRENT.

(To be continued.)

SCARCITY OF STARLINGS.

YOUR correspondent complains of the small number of these birds seen in Cheshire. I have made the same observation in Gloucestershire, which I attribute partly to the excess of cold in December and January last; and also to the number of juvenile sportsmen and idle men, with guns in their hands, during the whole of the frost. Not only are the Starlings scarce, but the poor Thrushes and Blackbirds also are reduced to less than half their usual numbers; and we lose a great portion of the beautiful notes of the two latter—which (next to the Nightingale), charm us during seven or eight months in the year. Such a slaughter of singing birds I do not remember since the year 1838, a frost which lasted more than six weeks.—H. W. N.

ABUNDANCE OF STARLINGS.

IN the neighbourhood of Wickham Market, Suffolk, I have seen them in very large flocks this month, and there are plenty about the farm buildings and pollard trees.—W. S.

HERE (Claughton, near Birkenhead), they have seemed more numerous than usual all the winter; and up to the present time. I suppose the severe weather caused them to seek the neighbourhood of houses for food and shelter, as they were scarcely ever absent during the winter from the projecting roof of a tall house near me, and now in mild weather they seem to have less shyness, and come nearer the door or the windows looking on to the lawn than usual—in fact, comport themselves with much the same boldness as the common house sparrow.—E. Q.

DURING the late severe winter I missed the flocks of Starlings that were wont to disport themselves in former winters, like small clouds buffeted by the winds, over the trees in Blenheim Park; but, most likely, ere your correspondent, "E. M." reads this, the usual number of happy couples will have arrived at the church, and to domicile themselves in their usual haunts in

Gawsworth—at least it is the case here (Woodstock), within this last week or two: and wherever they may have been, they appear in uncommonly good case, chattering, whistling, and snacking their bills, as much as to say, "Isn't this life and this fine weather really enjoyable, my spouse?" What beautiful-plumaged birds the males are! But the fraternity of them are dirty fellows in the immediate vicinity, when they were allowed to build in the roof of one's house. I take care to get the masons to stop all holes in the roof; but then there are plenty of trees with cavities in them—too many I am sorry to say for the sun shining on to this garden—to accommodate their impudences.—EDWARDS AND ONWARDS.

STARLINGS are very plentiful in this part of the country (Cardiff), they were also here in very large numbers during the whole of the severe weather we had last winter. I intend rearing some of those beautiful birds this season. Will you kindly inform me if you publish, or know of any book that is published, which could give me some useful information as to how the young birds should be treated?—W. J.

WITH regard to the scarcity of the Starling, I beg leave to say that I have found it just the reverse. I have not seen so many about here for several years as I have noticed this spring. They fly about in large flocks and build in precisely the same places as before. I have shot a good many, and find them in good condition and feather.—G. C. WHITWELL, *Kendal*.

VARIETIES.

THE GHOST OF AN IMPRESSION.—If a wafer be laid on a surface of polished metal, which is then breathed upon, and if, when the moisture of the breath has evaporated, the wafer be shaken off, we shall find that the whole polished surface is not as it was before, although our senses can detect no difference; for if we breathe upon it, the surface will be moist everywhere, except on the spot previously sheltered by the wafer. Again and again we breathe, and the moisture evaporates, but still the spectral wafer re-appears. This experiment succeeds after a lapse of many months, if the metal be carefully put aside where the surface cannot be disturbed. If a sheet of paper on which a key has been laid be exposed for some minutes to the sunshine, and then instantaneously viewed in the dark, the key being removed, a fading spectre of the key will be visible. Let this paper be put aside for many months where nothing can disturb it, and then in the darkness be laid on a plate of hot metal, the spectre of the key will again appear. In the case of bodies more highly phosphorescent than paper, the spectres of many different objects which may be laid on in succession, will, on warming, emerge in their proper order.

MALT WINE.—Notwithstanding the introduction of Cape wine, and the still more recently increased importation of those from France, home-made wines have kept pace with these imports; and as their manufacture becomes better known, there is no doubt but their qualities will be improved, and the prejudice which condemns home-made wines without deigning to submit them to a trial is fast wearing away. Combined with that, the manufacture of these things is becoming better known; and, doubtless, when they become still more so, and when they assume the proportion of some of our breweries and every point in the making and fermentation be as well known as that of our national beverage, we may reasonably hope to compete with the foreigner in producing an article of greater purity than his, and, though different in flavour, still equally agreeable, and when the palate becomes used to them, they will be immeasurably more wholesome. But it will likely be some years yet ere any extensive alteration in the mode of making these wines be brought about, the amateur, whose means are not, perhaps, equal to his hospitality, will, doubtless, be glad to learn a way whereby he can treat his friends to a glass of wine bright, agreeable, and strong, and at less than one-fourth of the expense of the foreign article. I purpose, therefore, to give a few recipes of the mode by which I have been successful in making wine; and I have ascertained from a friend still more noted for the contents of his cellar, some little points on the management of his wines, which I have his authority to impart. Commencing, therefore, with

one of the cheapest and best of home-made wines, I will detail the process by which it is made. At a time when the brewing is going on (for malt wine can only be made then), take 10 gallons of sweetwort, 10 gallons of beer that has been boiled with the hops, and has cooled and received some yeast, and 10 gallons of soft water; boil this water and the sweetwort with 45 lbs. of loaf sugar; and when it is nearly cool, mix it with the tunned beer, and let it stand eighteen hours in a tub; afterwards put it into a cask, and let it work about four days, filling the cask up with liquor that has not been in it before—not the yeasty portion that works out, which would prolong the fermentation—a thing much to be avoided; and as soon as it is about settled bung it down, giving it vent now and then by a vent-peg. The cask ought to be a fresh-emptied spirit cask, or a wine one will do. After it has stood a fortnight or so, put in 10 lbs. or 12 lbs. of raisins, and bung it down tight, only occasionally looking to the vent-peg. At the end of twelve months it will, if all be right, very much resemble sherry, and would be much improved if bottled off then; but we generally allow the bulk of ours to remain in the cask, and it improves much in three or four years. If it be too sweet, keeping will correct that, and the sweeter it is the longer it will keep. Observe, no spirit is added, neither does it want any—it is quite strong enough without any brandy; and as there is no acidulous fruit used in the making of it, the sharpness which fruits often give to wines is avoided. Some little judgment is required in proportioning the tunned beer: for if this be unusually heavily hopped, less of it must do; at the same time wholly sweetwort is also faulty. A smaller quantity than the above can easily be made, for as it is plentifully charged with fermenting matter from the tunned beer, it is sure to work, and a small quantity sooner becomes ready for use: but it is, perhaps, not quite so good, as, in fact, few wines made in small quantities can hardly expect to be so good as when more is made at a time. But when we can equal the foreigner in the extent of our operations, and also know the various points conducing to excellence, we may look forward to equalling him in the article produced.—AN OLD SUBSCRIBER.

OUR LETTER BOX.

DUCK'S EGGS WITH THIN SHELLS (*A Constant Reader*).—The shell of the Duck's egg is the result of faulty secretions, and we know not what medicine to advise for a Duck, because in our experiments on them we have tried calomel in doses from one grain to a teaspoonful without any effect. We know that on some waters the Ducks lay eggs with thinner shells than on others, and we know if they are very fat it is unfavourable to laying. We know not how you have been feeding; but we advise you to leave the bird full liberty, and to feed her on nothing but whole oats. The egg is only unfit for sitting because the shell would not bear it.

WENS WITH WENS ON THE CROP (*Constant Subscribers*).—Your hens are very much diseased, but judging from your description they need not be killed. They are suffering, probably, from fever, and drink immoderately; this causes the crop to hang down, and we fancy this is the wens you mention. Give castor oil, every day a tablespoonful, feed on stale bread soaked in milk, allow only a little water four times a day, and as soon as they have drunk take it away. We always advise that diseased fowls should be separated from any others. If they really have wens, an operation will be necessary.

DUCKING COCK WITH CONTRACTED TOE (*Subscriber from the First*).—The cock's toe bent under the foot is a very bad case, but not incurable, unless under one circumstance, which we will describe. If the thigh of the diseased toe is wasting, and less than the other, and if the knee swells, there is no hope, and it will be a charity to kill the bird. If such is not the case, give him castor oil every other day, feed him on oatmeal and bread and milk, and be careful that he never treads on anything but grass, hay, straw, or dry gravel or earth—no stones, bricks, or wood.

STOCKING AN OBSERVATORY-HIVE (*R. J. W., Preston*).—A second swarm should be lived in a common straw skep and knocked out on a sheet immediately in front of the uniomb-hive in the evening of the day on which it is used. The observatory-hive having been slightly elevated from its floor-board, a stream of bees should be directed towards it by means of a twig or feather. After all, the process is frequently very troublesome, and for this reason we avoid it altogether, by lifting our uniomb hive with moveable bars, which we place in a box, and having hived a swarm therein, and set it on the spot intended for the uniomb-hive, leave it undisturbed during three or four days, by which time good-sized combs are usually formed. Choosing the middle of a fine day, we lift out the bars with the adhering combs and bees, arrange them in the observatory-hive, and the job is complete. Glasses should be put on as soon as the stock-hive is pretty full of bees. The latter end of April is about the right time. Better give room too early than too late.

GOAT-KEEPING (*B. W.*).—You will see a short communication upon this subject in our columns to-day, but we hope to have more detailed information on the subject, and shall be obliged by any one sending us the results of his experience. We believe one obstacle in the way of Goat-keeping is the need of keeping a buck Goat as well as milch Goats. If several persons kept Goats in one vicinity, the fragrant gentleman in question might be joint-stock.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 62° and 40° respectively. The greatest heat, 81°, occurred on the 6th, in 1830; and the lowest cold, 21°, on the 8th in 1855. During the period 146 days were fine, and on 92 rain fell.

REFINED TASTE IN FLORICULTURE.

FTENER than once lately the question has been put to me—Do you consider that the education of a taste for any particular flower adds to your pleasure? and were you to strike the balance between the pain that you experience when a flower does not come up to your idea of what it ought to be, and the enjoyment that you have when

the reverse is the case, which would preponderate?

The answer to this opens a wide field of inquiry.

It has a great deal to do with the philosophy of human life—the relative value of earthly and spiritual things, and the present condition of our race. If the object of such a question be to depreciate the cultivation of taste, the education of the eye or ear, then “I will have none of it;” for, carried out to its legitimate conclusion, it would make the savage state the *beau ideal* of human life, and as effectually “snuff out” civilisation as the Pope would do. For, take the very commonest subjects—the mere speaking of our language: One who has passed through what is called a liberal education is most grievously racked with torture when he hears unfortunate letter H sacrificed, and people talking about “heggs,” “osses,” “am,” &c. Are we to say, therefore, that the pain he thus suffers would be at all to be compared to the enjoyment which he can alone appreciate when he hears, in clear, mellifluous, and classical language, our good English tongue well spoken. See a number of persons on Easter Monday going through the National Gallery, or the rooms where the Sheepshanks and other Collections are contained at Kensington. They think them pretty; and any of an amusing kind—some little scene of domestic byplay—is sure to have a crowd around it, who are admiring, not the artistic manner in which it is executed, but the naturalness of the scene. Follow that other quiet-looking individual—he will soon exhaust your patience if you are not yourself a connoisseur. See how he lingers over one picture, how vacantly he gazes on it, what brightness fills his eyes as he looks at each point. Ask him, if you will, what it is that so engages his attention—it is, perhaps, some clever management of light and shade, the delicate manner in which a sunbeam throws its light upon the floor, on the airiness of some fleecy clouds in the distant sky. What if he does come across an inferior production now and then and writhes under it, surely he never for a moment balances that with the thorough enjoyment he has experienced an hour before. And without much trenching on what is my own peculiar sphere, may I not ask, Is it not so in the far higher and more important concerns of religion? There can be no doubt that he who is really and sincerely engaged in the Christian warfare does feel more acutely the power and acting of sin than he who is merely contented with a cold and lifeless profession. But will the true Christian, with every feeling so finely strung, that

all discord jars his frame, say for a moment that he would forego the true and abiding peace which he enjoys because of that? Oh, no!

But I have wandered, perhaps, overwide from my subject; for, as I said, it enters largely into the whole philosophy of our being, and to deny the advantages of a refined taste would be to second the vagaries of that southern writer of whom Dr. Mackey speaks in his “Life and Liberty in America,” who wrote elaborately to prove that not only was slavery not wrong, but that it was the happiest condition of man, as all his wants were provided for without anxiety on his part.

But there is not only the enjoyment of looking at these things with a refined eye oneself, but there is also that equally great one—looking over them with brother craftsmen, who appreciate their properties as much as yourself. I have, let us say, a fine frame of Pansies in full bloom. Neighbours hear of it, and wish to see it. By all means! One feels a little pride on being able to point out some fine-looking and well-grown flowers, and hearing the exclamation, “How pretty!” “What a size!” But make way, ladies and gentlemen; here is one, who, not far off, has another collection. We sit down on the edge of the frame; we talk—some would say wildly—long over each individual flower; speak of large eyes, rounded and smooth edges, depth and intensity of colour:—time flies rapidly on, and we really wonder it has taken so long. Nay, what may seem stranger still—I have sat with friends on the edge of an Auricula-frame for hours, when not a pip was to be seen, quietly enjoying a talk about their properties, handling the gems of the collection, and speculating on the probable appearance in the next spring; and a quiet, peaceful enjoyment it was—it is needless to say utterly incompatible with an uneducated taste.

My object in writing thus is not merely to answer an objection which may be sometimes made to the pursuit of floriculture strictly so called, but at the same time to urge the positive side of the question. The advantage of cultivating some one particular class of florists’ flowers—Pinks, Pansies, Auriculas, Carnations, Dahlias, whatever it may be—I am sure would afford to many who have tried it great pleasure. The facilities for obtaining collections are now great. Florists are not the churls they used to be—they are ready to take and give, to exchange their surplus stock; and the diffusion of information on every subject of the kind leaves no room for ignorance, which must needs be wilful if it exist at all. Amidst the cares, business, and turmoils of life we all need something at times to turn to; and even where the pleasures of a garden—which, as Lord Bacon says (Essay xlv.) “is the greatest of human pleasures, and is the greatest refreshment to the spirit of man, without which buildings and palaces are but gross handiworks”—cannot from circumstances or position be entertained, there may yet be the management of a little frame filled with some favourite flower, whose care and culture at all times will afford the greatest enjoyment. I am not in the position of the fox who lost his caudal appendage and recom-

mended his friends to get rid of theirs, but rather of one who, having for many years served an apprenticeship to the craft, can confidently recommend it as the source of much true enjoyment both to myself and others.—D., Deal.

THE EXPERIMENTAL GARDEN.

POLYANTHUS CROSSING—RULE IN CROSS-BREEDING—NEW RIBBON-BORDER OF GERANIUMS.

THE owner of the Experimental is no more. The place is advertised for sale, but the executors allowed such plants as were not yet in the hands of the public to be removed to my private garden, and no contributor will be the loser by the mournful event but myself. It was in anticipation of this change that I announced, some time since, that I could not receive any more seedlings to prove. However, as every book and periodical which treats on gardening, every nursery and garden which keeps the subject alive before a willing public, and every exhibition, meeting, and committee which awards prizes for merit in our line, helps to keep up trade, to make a demand for gardeners, and to increase the innocent enjoyments of gardening pursuits, it is not good to let down one of such books or periodicals, nor one of such nurseries and gardens, nor one show, nor one opportunity of keeping the wheels and the wheel within the wheel in active motion: therefore, I shall in future devote my private garden on the principle that every little helps. What I see and hear I shall say; and what I shall think without seeing or hearing, I shall suggest to the end of the chapter.

Well, my "Good Gracious" has, this spring, more than ever proved that no kind of Polyanthus is so telling in our new arrangement of spring flowers as a yellow Polyanthus. No matter whose strain it may be so it is yellow, it is more valuable now than any, or all, that I have heard of or read about, from the days of Gilbert and his father-in-law to the present. My "Good Gracious" was not my strain, it only came by chance as did all Polyanthuses that ever I knew; but it is by far the strongest and the best bloomer I have ever seen, and the easiest to raise a good stock from, and to keep the plants after you once have them.

I have not the slightest merit in producing it, nor any interest in the sale of it, but I am bound to say it is far superior to any other kind of yellow Polyanthus for ribbon-lines; and in a few years, when it will have rest from excessive propagation, it will have the same run as the Shrubland Rose Petunia and Punch Geranium, and in all probability it will see them both out. Remember, the name was suggested to my friends at the Wellington Road Nursery from the exclamation, "Good gracious! where did you get such a Polyanthus as that?" but no one has since, or could since then, have seen such a stalk and such a truss. The plant has been so forced and so cut about that it has not had sufficient root-rest to show its character.

I kept four plants of it in 1859, and in 1860 I made one hundred plants from them on the system of propagation I wrote about, and now one of them with four leaves only has thrown up a nearly "Good Gracious" truss. I shall never cease talking about it till it is as common as Punch.

But I have an entirely new and independent strain of most beautiful kinds of yellow Polyanthuses from the gentleman who surprised me so much last year by his saying, these or this yellow strain came true from seeds and could be crossed. One of his strain is nearly white with a large yellow eye, one is light lilac all over, one is hose-in-hose and each hose as yellow as the flower, one a brownish-yellow, and one red and yellow after the fashion of Ghent Azaleas, one is as good a yellow as "Good Gracious" itself; but the bred seems much more dwarf than mine, though the plants were grown in strong, adhesive, black loam, while my garden is so light that I can push down a walking stick a yard deep in it as easily as into a cask filled with dry Reigate sand.

I recollect a very large dark blue Pansy which Mr. Barnett had in the Experimental Garden in Edinburgh, and which would come as true from seeds as a wild violet. Mr. Barnett is in the Regent's Park Botanic, and may, probably, be able to tell the origin of that species of Pansy, for an accidental kind it certainly was. Now, if any one knows another Pansy that comes always true from seeds, the two could be crossed, and their progeny would be genuine cross-bred plants. The same phenomenon

might occur in Primula, in Dianthus, and in all the genera which yielded to the operations of the florist anterior to the discovery of the influence of the farina of old authors, or the pollen of our times. But they are very rare exceptions indeed, and supposing any or all of these yellow Polyanthuses came quite true from seeds, my "Good Gracious" will not be worth a straw to cross them with. It is a *negative*, as it were, and I suppose them to be a *positive*, and I am old enough to know that it needs two positives to give birth to one true cross-bred plant. If either of the parents sports, it only follows a law of Nature; and the fact of man's assumption in crossing them is not sufficient to cancel a natural law, although the fact of one of the parents being a *positive*, or always coming true from seeds, may influence so many of the seedlings—an event concerning which I have no experience, and, probably, no one can tell me, because philosophical experiments do not pay in gardening in these days as they did in the early days of Knight, Neil, and London.

At this point I have a notice of a white Polyanthus in Norfolk, which I shall be very glad to receive, or any other peculiar seedling of Polyanthus that is likely to come true from seed, or to be influenced in its seedlings by a different soil and culture. Perhaps we may yet meet with exceptions to the theory of crossing florists' flowers in all the families except those in the Composite order. If there are two kinds of Polyanthuses in the world which will come true from seeds, they must give a true cross-bred crop. Pansies the same, and so with all the rest of them. But if we can improve spring flowers by the exceptions to a weighty law, we shall do well and learn something to the bargain.

Here, again, I have been called out of my sanctum to unpack another basket containing seven kinds of yellow Polyanthuses, two of them being different from those I received the previous week, and a yellow Primrose with a large orange eye. I should like to know how stands this form of the wild Primrose over the country. I think his majesty of the cross-breeders had some seedlings like it a few years since. The rectory garden and the garden to the National Schools at Surbiton are now one blaze of Primula bloom, all seedlings from my "Good Gracious" Polyanthus, and as good a strain of kinds as you could find in the three kingdoms; yet when the mother was in flower there was not another Polyanthus in bloom within one mile and a half of it.

I have one more selected kind I raised from a packet of the first seeds which Mr. Smith, of Harwich, advertised. I sowed a packet of every collection of Polyanthus seeds which were advertised since 1852, and there was very little difference in the seedlings, only that the whole of them, without an exception that I can think of, were good border flowers.

But what I was going to remark about the one I selected for a future parent is, that it is quite as sportive as the "Good Gracious" kind. Out of sixty seedlings from it not one is just like itself; but they are all nearly as good. These two, therefore—my yellow and the rich brown from the Harwich packet—are two negatives, or two sporting characters. Now, as I have just said, do you think if I were to cross these two best kinds in my garden I could induce two blacks to make one white, or two negatives to make one positive? Not a bit of it. The autumn of 1855 brought to a close a long list of experiments began in 1829 on purpose to decide that point, both for flowers and fruit trees. Good practical physiologists suggested the experiments, and I had to conduct them; but the gentleman who owned the garden died the year after, and hardly any account was ever given of that experimental garden. But the then Lord Chancellor (Lord Cottenham), and his father-in-law, W. Wingfield, Esq., a Master in Chancery, with the assistance of J. Bidulph, Esq., of the firm of bankers near Charing Cross, enabled me to keep the collection of plants from passing under a common sale, where everything else was sold. Much of the collection was got together by contributions, and for the credit of the craft it was a sore point to let them under the hammer. Mr. Knight, of the Exotic Nursery, valued the collection, and I undertook to have it sold by private contract. I did so, and got more money than the valuation. The Messrs. Dickson, of Chester, were my best customers in out-of-the-way plants.

That experiment was successful; but all the crossing experiments were entirely for searching out the secrets of Nature—not one of them had the least pretension to "improve" a flower. I do not know if Mr. Knight was convinced or converted to the plan of testing his own theory of improving fruits, but the arguments about two blacks making one white were used freely against

his doctrine; they were also multiplied at his own suggestion. The conclusion arrived at was that *any two species, kinds, or varieties which did not reproduce themselves true from seeds could not act on each other by the process of crossing so as to change their nature, and that no reliance whatever could be placed on obtaining a true cross-bred plant between them.* So that, in fact, if the Green Gage and the Golden Drop Plum do not come perfectly true from pure seeds, crossing the two could not be considered as producing an intermediate seedling. Apples, Pears, Peaches, and all of them, were catalogued in that category; and I would ask after another quarter of a century's practice if the fact can be shown to be really so or not; for I am far from being certain about any one thing respecting the crossing of plants.

I may be wrong when I say that no one has yet suggested the true way of improving any one of our common fruits; but I said so a quarter of a century back, and have received no answer yet; and if I live till the florist prove the doctrine of two blacks being able to make one white, I fear my memory will fail me in counting back to the years of our "Good Gracious" things. But if I were a young gardener now, and knowing such questions to be yet questionable, do you think that I could noodle away my time as some do at the present day?

But if no more baskets of plants come in to disturb the rest of this letter, I can tell of a nice ribbon-border I dreamed about the other night. It seemed as if it were a show day at Chiswick, that we were in the large conservatory, that some one tapped me on the shoulder from behind, that she was a fine-looking figure, on the right side of the censors; that she had the advantage over our conversation, and twitted me on the length of time it took to make a Berlin-wool-shaded border out of seedling Geraniums. "Yes, madame," said I, "but did you hear of that ribbon-border I made?" and it (the ribbon) struck me all at once; and I thought madame was going to strike me too with her parasol for very pleasure at the idea of the arrangement—I stumbled back a little, and was wide awake.

That ribbon began in front with a close row of the variegated Arabis set at 4 inches from the edge of the border, and measured nearly 6 inches across. The second row was 9 inches or 10 inches across, and took two rows of the Crimson minimum—the last seedling I sent out. This is one of the best telling of all the very small Geraniums. You would not know the flowers from those of Imperial Crimson; but the plant is not quite one-half so big as Imperial. For a front row it has no rival, and it is as easily propagated and kept as Imperial Crimson—thirty plants of it may be wintered in one No. 32-pot, without a misfit of any kind.

The third row was of the Golden Chain throughout, medium-sized plants, and occupying 10 inches across. The fourth row was my Victoria Rose Geranium; but as I cancelled that sort in favour of Mr. Kinghorn's Christina, you must take the latter which is all but the very same. I had these last two running side by side in 1860, and no two Geraniums can be more contrasting than the Golden Chain and Christina, nor than Golden Chain and Crimson minimum, for I saw the two together in 1859, which was about hot enough for both. As to the contrast between the variegated Arabis and Crimson minimum, I cannot dream that any one can make objections on that score. The fifth row comes more in combination than in contrast to Christina, it was of my Carmine Nosegay—the best bedding Geranium I ever originated; it is of a shade between lake and carmine, which no rain or sunshine can impair. It is just the next highest size after Christina, and between Christina and Tom Thumb. The sixth row was the strongest contrast on the border—a dark purple or atro-sanguinea colour; it was Stellatum, or the stellate Nosegay—a new style of flower, half way between a Nosegay and a Tom Thumb flower. The seventh row was Punch, one-year-old plants, and not trained down: up to the back leaves of Punch you might run a straight edge along the whole border to touch the tops of all the plants in the slope, although the border was a dead level. The eighth row was of old plants of the Cottage Maid horseshoe Geranium, the only horseshoe kind they plant now, largely, at the Crystal Palace. But I should, myself, prefer a globe-flowered Geranium at the back of Punch; for the Globe form of truss is just as good a contrast to the flat truss of Punch and most other Scarlet, as the Nosegay style of flower is on the other side; and without making strong contrasts in real good colours, a ribbon is not one half so telling as a plain sash, or a border all of Punch, Tom Thumb, or Crystal Palace Scarlet.

Last season I saw a new Globe Geranium from Mrs. Conway,

of Earl's Court, Old Brompton, which is, probably, the one which is now named Princess of Prussia in the Wellington Road Nursery; and if so, Mrs. Conway's seedling would be my Globe, and my last row on a wide-awake border; but in the dream the old Compactum, and two-year-old plants of it, was the plant.

Now, that certainly was a showy ribbon, and all of the very best Geraniums, with only an edging plant, as it were, for a bed for the front row. There were two more rows at the back; but from what the lady said when she missed the hit with the parasol, I shall never tell them or say a word about them.

D. BEATON.

A RAID AMONGST THE NEW ROSES.

EARLY days for this! Why not "bide a wee," when more fitting opportunities will be given, when the summer or autumnal bloom will be more in character, and when we can judge more correctly of what they are? My answer is, I see every day advertisements ament them; hear inquiries—"Are they as good as they are said to be?" "Is it safe to get them so early?" and many other questions of a similar character; and so, having had an opportunity of seeing some of the brood, I hope a few observations, made under what are, of course, indifferent circumstances, may not be unacceptable.

I say indifferent circumstances, for they must be so. The plants are removed in October or November, and as soon as possible every available bit is used for grafting. This is, of course, done in a very strong though moist heat. In a fortnight or three weeks the graft is pushing along. Away it goes with railroad speed; you may almost see it grow—it has not time to stop for anything. In a couple of months it has run up a foot, or a foot and a half. Now comes the cruel propagator. "We want Roses on their own roots," he says, "that's the cry now. Sir, these must go!" and so off come their heads. "But we want to see what they are." Very well, leave a few for blooming; and under such disadvantageous circumstances we must take our few notes. "The grain of salt is meted," and by-and-by we may have quite to modify our opinion of them. However, they are worth, I think, this much—that if a Rose shows well in such a position we may reasonably anticipate that it will improve, while we cannot positively condemn anything that may not look well now.

As the autumn of 1859 introduced several light-coloured Roses, so that of 1860 brought before us an unusually large number of high-coloured flowers. Some of these I have seen, and one I see characterised by some growers as the best of the season—I mean *Peine des Violettes*. Of this I feel confident, that that is very, very far from its true position; and unless it alters very much in the future it will not, I believe, be found "anywhere" in a year or two. No doubt its habit is vigorous, and on its opening day it is pretty; but its beauty is of the most short-lived character. It immediately in twenty-four hours assumes a dingy, shty appearance, gets lighter and lighter, until it perishes. Now, we found fault with *Géant* because he does something of the sort, but he is twice as long-lived.

As far as I have been able to judge, the best dark Rose is *General Washington* (there would be no wonder if *he* grew faint at seeing the fratricidal contest in the once *United States*). It is of a splendid shape, rich in colour, and very full, without being too much so. Its habit is good, and I shall be much disappointed if it be not *Al*. The charge of want of fulness cannot be made against *Madame Furtado*, figured in the May number of the "Florist" with Mr. Andrews' usual accuracy. The only question to my mind is, whether it will not be too full. The centre is filled with a large number of smaller petals, and there is a *La Reine* aspect about the flower, which makes me doubtful as to its opening well in the open air; but it is a beautiful Rose, and we may hope well of it. On the other hand, *Abdel Kader* is approaching more to *Général Jacqueminot*, of which it is probably a seedling: very brilliant in colour, and large in petals. Of its future I am also hopeful as a valuable and useful Rose. The gem of pot Roses is unquestionably a seedling of *Trouillard*—*Comte de Falloux*, one of the *Géant* race (I was wrong in questioning this, I think), but most abundant in flowering, never showing a shoot without a bloom, or two, or three. Brilliant in colour, and deliciously fragrant, forcing well, and growing well at all times of the year. Jean

Bart promises to be a decided acquisition, being one of the very dark Roses, of the Empereur de Maroc style, but vigorous in habit, holding a fine head of bloom, and showing well on the plant. Then, for hardiness, there is probably no Rose which will better (or so well) deserve the character than Madame Standish; not novel in colour, pink or rose satinée, but of very fine foliage and good form. Where others have perished around it in thousands, it has been comparatively untouched. It will doubtless make a fine pillar or trellis Rose. Then, amongst Teas, La Boule d'Or seems as if it were likely to be what it is said to be. Margottin does not usually say more than a flower deserves; and although I have as yet seen it only in bud, it promises well. Its habit is good, and the colour excellent: the yellowest of all Tea Roses.

If an amateur have the means of putting them into a *warmish* place for a while, and gradually hardening off, there can be no danger in getting Roses now; but on no account ought they to be subjected to cold, which will infallibly produce mildew. If had now, and carefully managed, they will afford buds in July for budding, and this should determine persons who can to get them now; moreover, the tops will now make good cuttings, and if *no time be lost* they will root rapidly enough. And such has been the havoc, that every one will be anxious to make as much way as possible in filling up vacancies.—D., Deal.

FORCING.

(Continued from page 62.)

GARDEN CRESS, WHITE MUSTARD, AND RAPE.

THESE are grown in many places all the year round for their seed leaves to be used as salading. On board ship they are generally grown in very shallow boxes of earth, or on thick coarse woollen cloths. To have it regularly, the seed should be sown every five or six days, and be placed in heat, from 50° to 65°, from the middle of October to the end of March. From April it can be grown out of doors, first with the protection of a hand-light, and then fully exposed, using a mat or a piece of calico merely to lay over the seeds before they are fairly up, when it should be removed in order that the tiny leaves may become green. As soil, nothing is better than old tan or decayed leaf mould mixed with sand. Shallow boxes are best in most people's estimation, though I prefer small pots about 4 inches in diameter, as the produce is easier cut; and as you cut two or three pots you can just remove the surface soil or fill afresh and sow again, which always gives a nice, regular succession. Whether, however, grown in pots or boxes, I prefer the surface soil to be made rather smooth, the seed sown thickly over it, so as to touch each other, and then gently pressed on the surface and watered, but no covering of soil or sand put over them, but covered with a piece of cloth or paper until they are growing. By this means the seedlings rise clean, and require but little washing in comparison with what they need when sand or light soil is thrown over them. The Golden Cress is more yellow in colour than the common. The Normandy Cress is very hardy, and where heat cannot be given should be used by those who like it. Sow in September and October for winter and spring, and in April and May for summer use.

CUCUMBER.

This, in northern latitudes, has received more or less forcing since the days of the Romans. In fine summers it is never more at home than out of doors in the south of England. Even at Sandy, in Bedfordshire, vast quantities are sown in the open ground in April and May, and the plants are thinned out like a crop of carrots or turnips, and allowed to occupy the ground. In fine seasons the produce is immense. In such seasons as 1860, this crop was next to a failure. Even those privileged with hand-lights and large glasses were not much more fortunate. These may be considered the means for furnishing Cucumbers to the working men in the late summer and autumn months. To obtain them in spring and early summer as well, hotbeds have to be resorted to. To get them all the winter, and all the year through, such beds and brick-pits heated by linings need to be resorted to, developing much skill and attention on the part of the gardener. For winter and very early spring supply it is now common to have heat supplied by hot water, or flues, or some means more certain and regular than dung linings, though, as stated above, great things have been done with dung and leaves alone.

There is a good old custom existing, where there is a large garden possessing every convenience for raising young Cucumbers, of giving a few plants in March or April to their neighbours who have only their two-light box and a small dung-bed. Keen amateurs, however, in general prefer sowing and raising their own plants. To save repetition, I would refer them to page 89 of the last volume, for the modes of preparing most fermenting materials, and at page 106 for the simple forms of frames and pits that will be most suitable—the first for general purposes, and the second for early or winter work. For the latter purpose we strongly advise a close wall; or, if there are pigeon-holes in the wall opposite the chamber either open or filled with rough stones, the floor above it, whether of slate, stone, or fine gravel, ought to be so close, or the soil kept so close to the sides of the pit, that no rank steam can find its way into the atmosphere of the pit. All such pits for winter and spring work should be heated by dung that has been only slightly fermented beforehand, so as to obtain all the heat that it can give. Economy will also be secured by straw hurdles or hurdles wattled with evergreen branches being set round the linings. For winter and very early spring work the plants will do better on a trellis fixed 14 inches or 15 inches from the glass than when the vines are lying on the ground. Early plants when so grown on a trellis we would prefer also to have in large pots instead of in a bed, as then there might be a chance in severe weather of increasing the bottom heat by putting sweet hot tan, or sweet hot leaves inside, and even elevating the pots a little without disturbing the plants. Such plants should be trained to a single stem before reaching the trellis, and then be stopped and trained in the usual manner.

Now for the minutiae as respects dung-beds.

Temperature.—However seasoned, it must be sweet, and sufficient to yield from 75° to 85° bottom heat, and an average of from 65° to 70° top heat, with a rise of 10° or 15° from sunshine. Long fancy kinds generally require a temperature averaging 75° to swell them long and regularly. That mentioned above will be high enough for such serviceable kinds as Cuthill's Black Spined, Ayres' Prolific, and the improvements on the Kenyon, as the Telegraph, and Cox's Volunteer, which are wonderful bearers; for such kinds as the smooth-skinned Kenyon, or Sion House, the most sure of all for winter supply, a top temperature ranging from 60° to 70° will be quite sufficient. The above will also give an idea of kinds. Fancy sorts of great length generally require much heat, and are not so prolific as shorter, hardier kinds. Were I a cucumber-eater, I should prefer them crisp, young, and from 9 inches to 12 inches long.

Size of Fermenting-beds.—This will depend on the season. If made in December, we would have them 5 feet high at the back, and 4 feet high in front. In January, 4½ feet, and 3½ feet respectively. In February, a little less. In March, 3 feet at back, and 2 feet 3 inches in front, and so on. For all beds, and especially early ones, we prefer them to be made as shown in fig. 2, page 106, of our last volume.

Time and Method of Sowing.—The first will depend on when the Cucumbers are wanted—say three months after being sown in December, ten weeks in January, two months in February, and so on. Before sowing, the bed should also be sweet. A small one-light box is often used for this purpose, but where there are other things wanting a little heat, a two-light box is the most economical. Use light rich soil for sowing in. It is generally advisable to sow in a six-inch pot, filling the pot about three-quarters full of drainage and soil, and then thinly covering the seeds, and placing a square of glass across the pot, and a piece of stone on the top of it, to keep all chance of mice away. If the bottom heat is more than mentioned, merely set the pot a little in, or on the surface of the bed. Use soil rather dry than moist, as a certain amount of moisture will be absorbed from the bed. If the seed is new, you may give a sprinkling of water in three days or so. If old, it is better to give none, or very little, until a few days more. When the plants are fairly up, water as needed, and sprinkle a little sandy peat and leaf mould amongst them. When they have made two or three rough leaves, pot them singly into four-inch pots, and water and shade until they are growing freely. When I wished to gain time, I put a good firm seed into a small 60-pot, and put several of them into a small hand-light in the bed, sinking the light a little to prevent vermin getting at them. These, when transferred to a larger pot, hardly ever feel the moving, and grow more vigorously, and require less care as to shading. If not quite certain about the heat of the bed, or the due warmth of the soil, we place each

plant into a six-inch pot, and that kept near the back of the bed is sure to be hot enough, plunged, half-plunged, or merely set on the bed, according to the heat; as too much heat at bottom is as enervating as too little is retarding. Both extremes produce a sickly habit, and invite the attacks of insects.

Soil.—Whether for seedlings, or plants to be turned out in the bed, the soil should not be much below 80° in temperature, we would rather have it at first 5° more. If 4 inches or 5 inches are spread over the bed, that could be collected into ridges, or hills in the centre of each light. From 12 inches to 15 inches deep will do for Cucumbers. So much nourishment escapes from the dung that for early work the soil should be light rather than very rich; for early work in beds, and winter work in pits, nothing answers better than three parts of heath soil, and one of leaf mould, one of fibry loam, and one of silver sand. For places heated by hot water, we would in winter have equal parts of heath soil and fine aired leaf mould, with a little silver sand. As the spring advances we use any light soil, as equal parts of sandy loam, and leaf mould; and as summer comes any good garden soil. In May we have used equal portions of stiffish loam and rotten dung, with fine effect; but we should never dream of such a mixture in February.

Planting out.—When the heat is sweet, known by the condensed drops on the glass being as clear as dew, and the soil is warm enough, the plants may be turned out of their pots, either three plants in a hill of soil, some 15 inches high and 18 inches through, or in a ridge in the centre of the bed, only a few inches nearer the back than the front, and in that the plants may be put out separately, and at equal distances apart, three plants to a light. In planting after April we would have one plant to a light in preference to more; but in January and February we prefer three, because we thus get so many fruit earlier. Besides the ridge of soil in the centre, and a little over the surface of the dung, it is also advisable to have a ridge of soil close to the sides of the frame; so that when the plants grow freely, and the roots protrude through the central ridge or hills, a little heated soil from the sides may be added to them.

Training.—The young plants should have the points nipped out when they show the third rough leaf, a secondary shoot will show from the axil of each leaf. If three plants are put in a light, only two of these secondary shoots should be kept to each plant, one to be trained and pegged down to the back, and the other to the front; all others should be picked out with the point of a knife. If fewer plants are used, more secondary shoots should be taken from each. These secondary shoots or bines we would allow to grow from 15 inches to 18 inches before stopping, if good continuous bearing is desired. If early fruit is the main consideration, we would stop these shoots when 6 inches long, merely nipping out the terminal bud. In either case the side or tertiary shoots from these main secondary ones will most likely show fruit at the first joint, or the second, and must be stopped by nipping out the point there, or the joint above. When the plants are young and vigorous, every fresh joint made must have the shoot stopped at the next joint, and this with removing old leaves, and giving room to younger ones, constitutes the chief amount of training and pruning the plants will require. When the plants show signs of exhaustion, the allowing several shoots to grow 18 inches or 24 inches, or even more, will renew its strength, and the older shoots may be removed; and the younger shoots being stopped, will give plenty of bearing side shoots as before.

Watering.—The water should always be as hot as the soil, never below 80° for early work. For all early work clear soft water is best. As the sun acquires power, and the days lengthen in April and May, weak manure waterings will be an advantage. Young plants in dung-beds will need little water at first, as in dull weather there is apt to be an excess of moisture. Even then they must not be allowed to become too dry. But in giving a little beware of saturating the soil farther than the roots extend. On a bright day the plants might be slightly dewed from a syringe early in an afternoon, and the boards of the frame at back damped, especially if banked up as shown in section 3, page 107 of our last volume. This will cause a fine dew to be deposited on the leaves during the night. Towards summer the leaves may be syringed all over during an afternoon, but that would give too much damp in January or February.

Ventilation.—In the early months of the year little can be given, and yet maintain the necessary heat. That little, however, should not be neglected, as all enclosed atmospheres with plants in them, and especially in cloudy weather, become impure. If

the heat will permit, a little air should be left on the back of the frames at night, though only the sixteenth part of an inch, and one-eighth would be better still, even if a piece of muslin were stretched along the opening. Means must be taken, however, to prevent the steam from the linings entering at that opening. In early spring the uncovering of the beds will lower the temperature, and, therefore, an hour before uncovering, the air might be all taken away, and a little given afterwards as soon as the sun began to operate on the frame. Much success depends on early air-giving. If very sunny a little more will require to be added as the sun gains power. If kept close too long before air is given, giving much at once is often very injurious. For instance, in a frosty day, the sun is bright and raises the bed shortly that has no air on to 90° or 95°—sufficient in such circumstances to scald the plants; and if enough of air is given to sink the bed shortly to 80°, a burning, cold, dry air completes the mischief the scalding had begun. Suppose the covering had been removed at 8.30 in the middle of March, and the thermometer was then at 70°, and the sun was bright, a very little air given when it reached 75° might prevent it reaching above 80° altogether; and if it rose a little higher a little more might be admitted and reduced after noon, and taken away altogether early in the afternoon. By giving a little thus early, too, there is no occasion to run to the bed every time the sun enters or emerges from a cloud. Acting on this principle, we have known amateurs very successful who never could look at or do anything to their frames from 9 A.M. to 4 P.M. They became shrewd guessers of what the day would be, and never left home without leaving a little air on. When more is necessary at an early season, the sashes then, and always, should be tilted or raised up at the back, never slid down, and a piece of woollen net or cotton muslin might be stretched across the opening. The shutting in of the sun's rays early in the afternoon is of importance, even if you give a little air after covering up for the night.

Protection by covering for early crops will be needed, less or more, from November to the middle and end of June. Russian bast mats are generally used, and thicknesses must be given from one to four in proportion to the weather. They are littery, dirty, and expensive at best. Asphalt or wooden covers are far superior. A waterproof cloth or canvass, with woolly matter inside, is very good. In severe frosts, a piece of calico large enough to cover all the glass, a little dry hay sprinkled over it, and a waterproof cloth over all, would suit many amateurs, and be nice and cleanly. In severe weather the covering should be on early in the afternoon, and be off by nine or ten in the morning. In extra severe weather it may stay on for a day, but in general the plants should have light every day, though even for a short time. As the days lengthen the covering should not be on so as to intercept any direct sunlight. When fire heat can be given, it is easy to raise the temperature a little before uncovering.

Increasing Heat.—This, in such circumstances, can only be done by means of linings; or if the plants are in pots, even in dung-pits, forking up, and adding a little sweet fermenting material to the inside among the pots. It is advisable not to let the heat inside become too low before the linings are turned, or fresh additions made to them. It is also best to do the front at one time, and the back at another. The bottom heat must also be ascertained by means of a ground thermometer, or by a trial stick put in the bed; for a little practice will enable you to tell at once near the temperature, by feeling with the hand a stick an inch in diameter that has been thrust firmly into the soil. If the bottom heat is deficient, then the lining must be turned to its base, and some fresh material used. But in most cases in a period of dull weather the top heat will languish, when there is quite enough at the roots of the plants, and in this case the turning and the addition must not go lower than the surface of the soil inside. With beds made as in fig. 2, page 106 of our last volume, and well banked up round the frame, we have had Cucumbers growing from January to September, and the lining was never turned to the bottom, because the bottom heat was always high enough. In such turning of linings care is always required, by pressing the soil close to the sides of a box, to prevent any rank steam entering. Of course, in a close-walled pit this care is little required. I have forgotten to add, that in covering this also must be looked to—the covering must not hang over the linings in front if any impure steam arises from them, as thus it might be sucked in between the laps of glass, &c. Inattention to this has ruined many plants.

Cleanliness.—The back of a frame and of a pit should be washed with lime and sulphur, and the glass should be kept scrupulously clean inside and outside. In frames and pits, too, it is a good thing to have other lights of a similar size at an early period, so that clean dry ones might take the place of dirty damp ones, by exchanging for a time. This exchange might be made quickly in weather when to attempt to clean the inside of the glass might be ruinous to the plants.

Shading.—If the plants are planted from 12 inches to 15 inches from the glass, and air is early given in the morning, shading will be little wanted, and the less the better. The times when it will be chiefly required for such tender things as young Cucumber plants at an early season, are when a very bright day comes after a period of dull weather. The plants are then rather enervated, and unfit to meet the demands at once made upon them, in the way of perspiration, and the assimilation of carbon. Water may not be at all necessary, and yet they may show signs of flagging and distress; a slight sprinkling or dewing of the foliage and the sides of the frame with water may arrest the evil. Sprinkling even the outside glass from the syringe may serve the purpose by breaking the force of the sun's rays; but if that will not do, an evergreen branch or thin bunting must be resorted to, but never longer than it is required. Some people shade from the sun in the forenoon, and let it continue on in the afternoon, long after the sun is beclouded; no wonder that such plants have to cry out for shading. Unless after such extremes, with air on, and the leaves far enough from the glass, shading should only be thought of as a necessary evil. R. FISH.

(To be continued.)

CANON HALL MUSCAT VINE IN A GREENHOUSE.

PINCHING PEAR TREE SHOOTS ON A WALL—GOLDEN DROP PLUMS FALLING.

I HAVE a very vigorous Canon Hall Muscat Vine growing in a greenhouse, which shows fine bunches, but never sets well, only a few of the berries coming to perfection. If I were to give it more heat while in bloom would it do to keep it cooler afterwards?

Would it answer on a wall well filled with Pear trees to keep them constantly pinched in, as the long shoots are a great eyesore?

Our Golden Drop Plums after setting their fruit very well, scarcely ever bring half a crop to perfection; dropping off when quite small. Can you suggest the reason? The borders are of a deep, strong, cold soil, in Worcestershire.—AN OLD SUBSCRIBER.

[Try and keep back your Canon Hall Muscat as long as possible. In a greenhouse it should not be in bloom until well on in June. At that time it should not be lower in temperature than from 65° to 70° at night, and you may allow it to decline after it has set and begins to swell. See what is said about Muscats in "Doings of the Week." For a greenhouse where a high temperature is not required, a Canon Hall is a very unsuitable Grape; but by the above means you may ripen it late in autumn, more especially if all the greenhouse plants, properly so called, are removed by the middle of June, and plants requiring more heat introduced. The sun will give great heat after that.

You may pinch the points of most of your Pear shoots when four or five inches long; but it would be good policy to leave a number of shoots, and if unightly break them half in two and fasten them to the branches. In strong-growing trees, if all the shoots are pinched in at once, there is a danger of starting into wood-growth what would otherwise have been fruit-buds.

The roots of your Golden Drop are most likely too deep; either raise them or remove a portion of the surface soil. Probably after all, Nature does what the gardener will hardly do—thin in time and thin enough—as such trees when they bear a very heavy crop one year, are apt to take a year's rest by way of revenge, and telling us how they ought to be treated.]

RHODODENDRON FALCONERI, which has the most handsome foliage of all the varieties I am acquainted with, has now a magnificent truss of bloom consisting of twelve blossoms, each about 2 inches in diameter, of good substance, and of a delicate, creamy white, with a slightly streaked purple throat. The foliage is a little damaged, caused by my subjecting the plant last season to sudden and severe changes of temperature, with

the object of blooming it.—JOHN STEVENS, Gardener, Malvern Hall, Solihull.

THE WILD FLOWERS OF GREAT BRITAIN.*

THE first Number of this serial is now published, and we have no hesitation in saying that its four plates with accompanying descriptions are the cheapest coloured illustrations of British wild flowers ever offered to the public. We may add that the drawing of the plants shows an appreciation of their natural habits superior to any that had before been employed upon our native plants. The colouring, all done in water colours and by hand, is also perfectly accurate.

The Number contains Borage (*Borago officinalis*); Yellow Meadow Vetchling (*Lathyrus pratensis*); Marsh Woundwort (*Stachys palustris*); and Creeping Cinquefoil (*Potentilla reptans*). The work is so printed that the purchaser can arrange the plants according to any system he prefers, and to enable this to be done, indexes alphabetical and systematical (Linnean and Natural), will be given with each volume. It is intended to give, as circumstances may justify, two or more drawings of species of the same genus on some of the plates. We extract the following as a specimen of the contents:—

"BORAGO OFFICINALIS. Linn.

"Common Borage.

"Nat. ord., Boraginaceæ. Linn. arr., Pentandria Monogynia.

"ESSENTIAL CHARACTER.—Limb of the corolla flat, much longer than the tube; mouth with a double row of valves, the innermost awl-shaped, bearing the stamens.

"SYNONYMS.—*Borago officinalis*, Shop Borage, Gray's Arrangement, ii., p. 350; *Bronwerth*, *Tafel yr ych*, Welsh.

"DESCRIPTION.—*Root* tapering, mucilaginous, as well as the herbage, which is clothed all over with very sharp bristles. *Stem* erect, with spreading branches 1½ to 2 feet high, round, spreading, leafy, and covered with rigid hairs. *Leaves* alternate, ovate or oblong, wavy, and more or less toothed; the lower ones broadest, stalked, and eared at the base; upper ones stalkless. *Flowers* numerous, on long foot-stalks, in terminal drooping bunches, very beautiful. *Corolla* an inch broad, of a most brilliant blue, pink in the bud. *Stamens* very prominent; valves and anthers prominent, blackish. *Seeds* wrinkled and warty, of a light shining brown.

"TIME OF FLOWERING, &c.—The plant is a biennial, and flowers all through the summer, commencing about the end of May and beginning of June.

"HABITAT.—It is found on waste ground, among rubbish, generally on soils charged with nitrogenous matters. It is frequent in most counties, and is generally believed not to be indigenous, but at some period to have escaped from cultivation.

"VARIETY.—There is a variety with white flowers found on entering Sandwich from the Deal side."

HISTORY AND USES.

"No such a term as Borage occurs in the writings of the classic authors, and the origin of the name is very doubtful. Lyte, in his translation of Dodonæ's Herbal, published in 1573, says, 'The ancient fathers called it in Greek *Bouglosson*; in Latin *Lingua bubula*, *Libanium*, or *Lingua lovis*, that is to say, *Langue de bœuf*, or *vache*; in English Oxe tongue, the apothecaries name it *Borago*, and accordingly it is called in Italian *Borragine*, in Spanish *Borraja* and *Borrajenes*, in English *Borage*, in French *Bourroche*, in High Dutch *Burretsch*, and in base Almaine, *Bernagie* or *Bornagie*.' Now all these European names are evidently derived from one original, yet no one has yet detected it—at least we do not seem satisfied with the derivation from Apuleius Platonius. In this most early of Herbals, written in the fourth century, and the printed copies of which are among the rarest of books, he states the Bouglosson of the Greeks was called at Lucca, '*Corrago*, quod cordis affectibus medetur.' Now Corrago is a very good name both in sound and sense, because the herb was then believed to strengthen the heart (cor); but why, against all precedent, change the first letter into B? making the name nonsensical. Even the name in Apuleius is uncertain; for in an edition without a date printed at Basil, and containing the works of Soranus, Oribasius, Pliny, and L. Appuleius

* *The Wild Flowers of Great Britain*. Illustrated by coloured drawings of all the species, by Charlotte Gower, and botanically and popularly described with copious notices of their history and uses by Robert Hogg, LL.D., F.R.H.S., and George W. Johnson, F.R.H.S., Editors of THE JOURNAL OF HORTICULTURE, &c. London: Office of the JOURNAL OF HORTICULTURE AND COTTAGE GARDENER.

Madaurensis 'De Herbarum Virtutibus,' we find, cap. 41, of the last-named, is 'Nomina et Virtutes Baglossæ.' He there says, in enumerating the names by which it was called in Greece, Egypt and elsewhere '*Lucani Carroga*,' and in the margin is another reading, '*Lacones Corrago*.'

"We think the most probable derivation of the name Borage is from that made use of by Myrepsus, who wrote in the fourteenth century. He describes the plant under the title of *Pourakeon*, evidently derived from *Pōrēō*, unhappy, and *akeo*, to cure, alluding to its supposed medicinal qualities. The change of the P to B in proper names was very common, and then *Bourakeon* is the Greek derivative.

"However, whatever may have been the origin of the name, there is no doubt that our forefathers attributed to this plant great invigorating powers. Their directions for its use in medicine are a tissue of superstition and symbolical nonsense—'three thyrses of seed' to be given in the tertian ague, and 'four thyrses' in a quartan!

"It was one of their four cordial flowers; and Parkinson affirms in his 'Herbal' that 'the leaves, flowers and seeds, all of them, or any of them, are very cordiall, and helpe to expell pensiveness and melancholic, that ariseth without manifest cause, whereof came the saying—

"Ego Borrage gaudia semper ago,"

which has been freely translated into—

"I Borage,
Give courage."

"If this plant ever possessed the power of vanquishing 'Blue Devils' and placing 'L'Allegro' triumphantly in their place, it is another symptom that the powers of this world are departing. At all events Borage is no longer used in pharmacy; and though its use still lingers in the preparation of cool-tankards, and the beverages well known at Cambridge as cepas and cider-cup, yet we suspect that the hilarity to which they give birth is attributable to the liquor rather than to the Borage leaves.

Its young shoots, which have a slight cucumber flavour, are sometimes an ingredient in salads, and sometimes are boiled like spinach. The caterpillar of the Gamma Moth (*Noctua* (*Plusia*) *gamma*) feeds upon the leaves. Its flowers afford abundance of honey to bees, and hence it deserves to be cultivated near apiaries."

KIDDEAN MODE OF HEATING.

I HAVE applied the Kiddean plan of heating to a small greenhouse I have just built, and I am much pleased with the economy and completeness of it. Perhaps some few particulars may be of interest to those of your readers who, with myself, have a great liking for flowers, but small means for gratifying their taste. My garden is one of the regular London slips—80 feet long by 16 feet broad, with a north aspect, and worse still, without sun for three winter months. At the bottom of this I have put up a span-roofed house 20 feet long by 16 feet wide, using the side and end walls of the garden for the walls of my house. Then came the question, How was I to heat it? I could not very well have my stovehole in my neighbour's garden, and one in the front of the house would have been very unsightly, besides taking up valuable space. So I decided on having my furnace inside the house; of course you will say, Wrong decidedly. I know that, but I had to do the best I could under the circumstances; so in the north-west corner I built up a glass partition 5 feet by 4 feet, taking care to get it as air-tight as possible, so that no smoke or dust can get into the house. Here I have my stovehole, and I fancy I shall be much more comfortable when I light my fire on a snowy night with everything nice and dry, than if I had to get into a wet well of a hole outside, though that would be the orthodox fashion. My furnace is 2 feet long, 10 inches broad, and 1 foot deep. I built it with fireclay, which, by the way, was a horrid sticky job. The top of the furnace is an iron plate three quarters of an inch thick, well bedded in fireclay, so as to make all tight. I used this because I found I could not manage so small an arch with bricks. A small flue takes the smoke out of the house by the nearest way. The air-chamber is 6 inches from the sides of the furnace, and, perhaps, 9 inches at the top, which is a piece of flagstone. The openings for cold air in the stove-hole are 6 inches square, and in so small a house as mine I dispense with flues for the hot air, and have instead two openings of 6 inches square at the further corners of the top of the chamber—i. e., just in the greenhouse. I find the hot air rushing in two copious streams into the house

within fifteen minutes of lighting the fire. On Saturday the 27th ult., when it was raining and snowing, I raised the temperature from 42° to 63° at the end of the house furthest from the air-holes within the hour, and this with two or three shovelfuls of ashes from the dust-heap with a bright coke or coal fire, I could have got 10° or 15° more. I found the air as it leaves the hot chamber was about 112°, but a yard above it the thermometer only gave 72°, showing how rapidly the heat must be diffused. By pouring water into the chamber I got a delightful moist heat, and to crown all, six hours after the fire was out I still found warm, not hot, air issuing from the chamber. I think by this plan I shall be able to set my great enemy—damp, at defiance. Of course, when the fire is alight the door of the stovehole shed is closed, the cold air for the furnace coming in through a window in the side. Can I have Vines without hurt to my plants if I only let them be on one side of the house, and let none of the branches come beyond the apex? I find my house altogether will cost me under £5, but then I have done everything myself. If any of your readers would like to know how I went about it, I shall be happy to give fuller details. I have had so many wrinkles and helps from 'THE COTTAGE GARDENER,' that it is only fair I should do what little I can to help others who have not been quite so long dabblers in gardening as—W. A.

POMOLOGICAL CLEANINGS.

PRINCE ALBERT GRAPE.—Do any of our readers know the Prince Albert Grape? It is very like Barberossa, and by some considered synonymous with it; but there is some reason for believing them distinct, the Prince Albert being said to be three weeks or a month earlier than Barberossa. We shall be thankful for any information on the point.

HOW SEEDLING GOOSEBERRIES ARE SENT OUT IN LANCASHIRE.—When a seedling Gooseberry has proved worthy of being let out, which is generally when it is four or five years old from the seed, the owner cuts all the wood from the seedling trees, and with the young plants, divides it into twenty-one lots. He then gets twenty-one subscribers, who take it at 10s. 6d. per lot. The old stool is sold by auction to the highest bidder, in some cases fetching £1 or £5. The seedling plant of Catherine was sold for £3, and Napoleon le Grand, £5 5s. In some instances a lot would not weigh 1 oz., and this causes them to be scarce for some years after being let out.

EFFECTS OF LAST WINTER ON PLANTS IN ENGLAND.

(Continued from page 19.)

I AM in the central part of Somerset; soil a rich loam. A *Magnolia ferruginea* as a standard, covered with only its extremities cut, whilst *Laurastins* close by is apparently killed. I housed my Tea Roses all but four, one of which is Madame Williams, and which were deeply covered in snow. The four that remained out are doing remarkably well, all on their own roots; whilst of hardy *Perpetuals* on the Dog Rose I have lost more than 200, some of them four years old. For the future I intend having all on their own roots.—J. A. P.

CRYSTAL PALACE SCHOOL OF ART, SCIENCE, AND LITERATURE.

—The Committee of Directors lately arrived at an important decision in respect of the admission-fee to the important and interesting course of scientific lectures which have lately been given by Dr. Dresser and Dr. Laakester in the private lecture theatre of this school. The fee has been wisely reduced to a minimum; and with the unrivalled educational facilities possessed in the collections of the Palace, when used by such talented men as those whose names appear on the announcements, these lectures will become not only an important adjunct to the various classes, but a recognised element in public education. For the remainder of the term, which closes here in July, Dr. Dresser is announced to give a summer course of Botany, the lectures to be illustrated from the great collections of growing plants belonging to the Company as well as from the Technological Museum. He is also to instruct in the dissection of flowers, and to give demonstrations on the commons round London. Such advantages as these are not possessed, we believe, in any other botanical school in the Kingdom. The fee for the course is to be only 10s. 6d.

SIX WREATHS OF FLOWERS.

WREATH THE SECOND.

"What fashion will you wear the gayland of?"
SHAKSPEARE.

It shall begin with *STATICE IMBRICATA*, a native of Teneriffe, flowering during our summer months, but requiring to be grown in a greenhouse. It was introduced by Mr. Webb in the year 1819, but was lost by our cultivators, and was re-introduced by the same gentleman, who supplied it to one of the French nurserymen about the year 1848; for we know that it was blooming at Paris in 1849, and was then considered "perhaps the finest Sea Lavender in cultivation." The leaves have their lower parts cut into pinnatifid oblique lobes, the upper end being one large, entire lobe. The flower-stem rises from 18 inches to 24 inches high, having its head corymbose and corymbosely branched. The flowers are numerous; calyx cup-shaped, crenated, persistent, and of a rich blue colour; petals small, fugitive, and cream coloured.

It may be propagated by divisions of the young plants, and by cuttings of the side branches. These cuttings must be thus prepared:—Make an incision sloping upwards about half way through the stem of the branch, and keep the incision open by inserting in it a small wedge of wood. In about a fortnight the wound will have cicatrised, and then if a little damp moss is tied over it roots will strike into the moss almost immediately, and then in two or three weeks the rooted cutting may be separated from the parent plant, and potted. The same mode is required for cuttings of *Statice arborea* and some others.

Next in our wreath let there be *CATTLEYA ELEGANS*—a splendid stove Orchid, but, perhaps, only a variation of *C. superba*. It was introduced from St. Catharines, Brazil, by Messrs. Backhouse, of the York Nursery, in 1852. It has club-shaped stems, ovate-lanceolate leaves, and a short raceme of large flowers. The sepals and petals are coloured bright, rosy pink; the three-lobed lip, furrowed and undulated, has its two outer lobes pale pink, but the centre lobe is large, and dark, rich purple.

Third in our wreath shall be another Orchid, but of more graceful form—*BARKERIA MELANOCALON*. It was introduced from Mexico into Belgium about the year 1818. The stem is straight; leaves ovate-lanceolate, distichous, and the flowers in a gracefully drooping raceme. The sepals are linear-lanceolate; the petals narrow-oval, and the lip two-lobed; the whole are partly rosy-lilac and partly purple. It flowers during the summer months.

Fourthly, let us have another Orchid, *ONCIDIUM HEMATOCYLUM*, but with very differently coloured flowers. It is one of the most beautiful and graceful of its very graceful genus. It is bulbless; leaves oblong, flat, thick, sharp-pointed, and very regularly and thickly spotted with brown. The sepals and petals have a warm greenish-yellow tint, strongly blotched with rich chestnut-brown; whilst the lip is of the richest crimson, softening at the base into a bright

rose colour. The crest, by which it may be distinguished from other Oncids, is like the letter W, having behind a flattish space, and in front a well-defined projection, with a small tooth on each side. It flowers in September and October. It is a native of New Grenada, whence it was imported by Messrs. Loddiges in 1847.

Lastly, and it must again be an Orchid, though of very different form and habit—*CYPRIPEDIUM LOWI*, or Mr. Low's Lady's Slipper. It is found growing on trees in the thick jungles of Borneo, whence it was obtained in 1846 by Messrs. Low, of the Clapton Nursery. The flowers open at the close of summer and early in the autumn. The sepals are ovate, downy externally, green, with a purplish tinge at the base. The petals are long, spatulate, curving, greenish-yellow, blotched with purple and violet purple; margins hairy; lip pouch-shaped, purplish-green, shining.

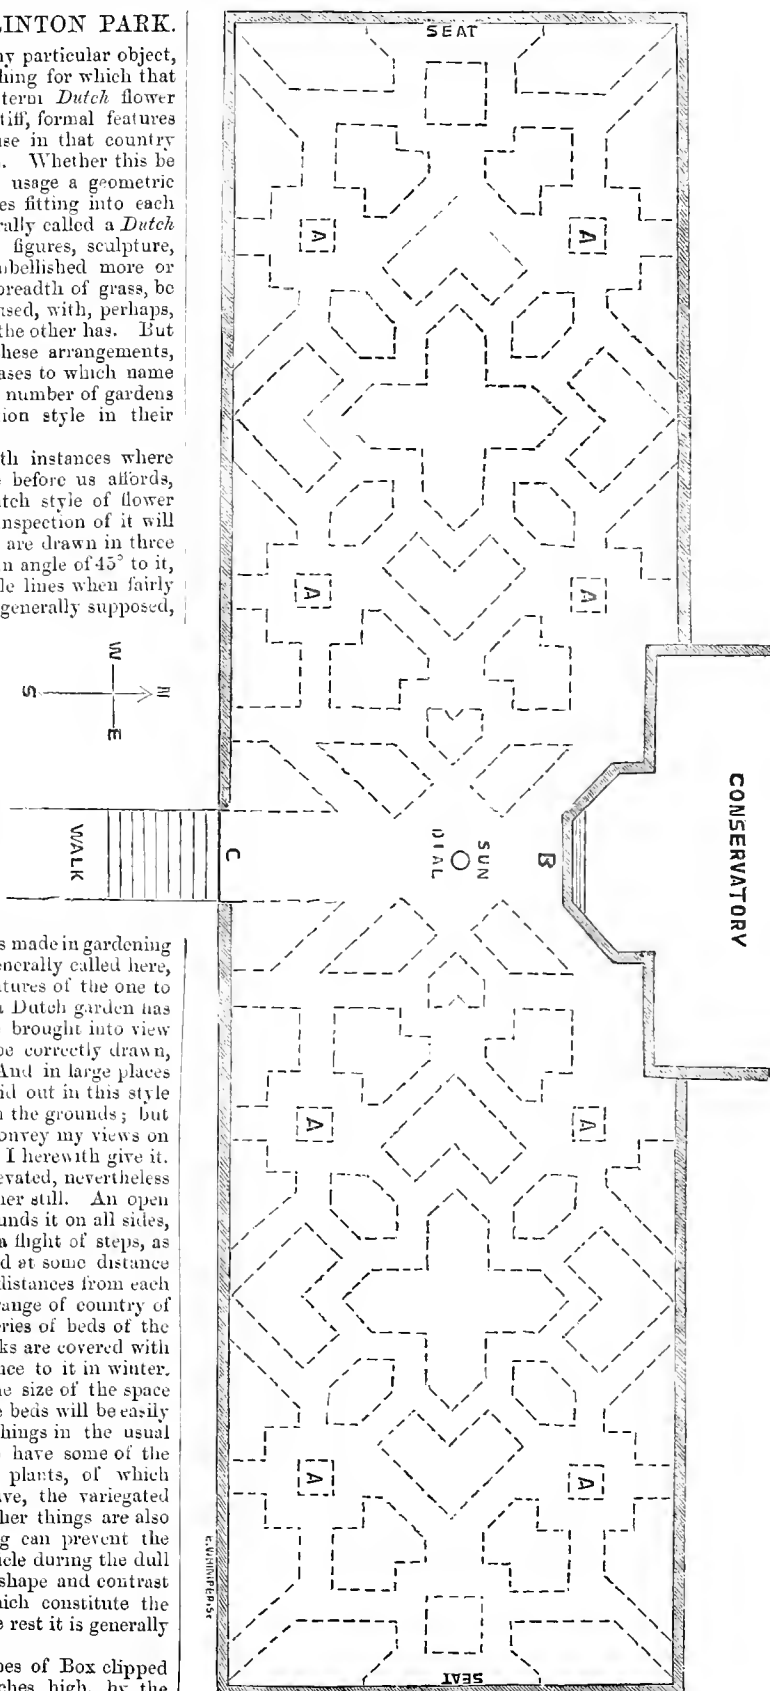

DUTCH FLOWER GARDEN AT LINTON PARK.

WHEREVER a national name is given to any particular object, it is supposed the object represents a something for which that country is famous: therefore, in using the term *Dutch* flower garden, we may reasonably infer that the stiff, formal features it usually presents were those in common use in that country when the style was introduced into England. Whether this be so or not, certain it is that by conventional usage a geometric garden, consisting of simple lines and figures fitting into each other and occupying a given space, is generally called a *Dutch garden*; but if, in addition to these formal figures, sculpture, vases and long-continued lines of walks, embellished more or less with symmetrical planting, and a large breadth of grass, be introduced, the term *Italian garden* is then used, with, perhaps, less claim to that country for its origin than the other has. But it is not necessary here to find fault with these arrangements, and it is also hopeless to determine in all cases to which name certain geometric gardens belong, the greater number of gardens present so much of the mixed or transition style in their composition.

Nevertheless, we now and then meet with instances where each class is fairly represented, and the one before us affords, perhaps, as good an example of the pure Dutch style of flower gardening as is usually met with. A slight inspection of it will show that the straight lines forming the beds are drawn in three directions only—which is a base line, one at an angle of 45° to it, and one at right angles. These three simple lines when fairly carried out give much greater variety than is generally supposed, and the number and shapes of flower-beds may be infinitely increased where there is space to do it by only using these simple lines; and to those not well versed in mathematics it is only proper to say that many mechanical works are done on that principle, and some time ago an engraving of a dwelling-house near Edinburgh appeared in the *Builder* paper in which these three lines and two more intermediate ones were brought into play with good effect. And assuredly gardening gives as much scope for variety as building; for with all the examples of ancient and modern art around them architectural inventions have made little or no advance, while a great stride is made in gardening matters, and the easy natural style, as it is generally called here, in a great measure superseded the formal features of the one to which the present engraving belongs. Still a Dutch garden has its advantages, as a vast floral display can be brought into view at one place, and assuming the edgings to be correctly drawn, the appearance is pleasing even in winter. And in large places where variety is wanted, an insulated plot laid out in this style is often as interesting as any other feature in the grounds; but a description of the one now before us will convey my views on this matter better than a mass of generalities, I herewith give it.

The garden here shown is considerably elevated, nevertheless the conservatory at the north side of it is higher still. An open work balustrading of a fanciful pattern surrounds it on all sides, except where it joins the conservatory, and a flight of steps, as shown, leads from it to the terrace below, and at some distance beyond are other flights of steps at certain distances from each other—the whole pointing to an extensive range of country of many miles. The garden is composed of a series of beds of the form shown all edged with Box, and the walks are covered with white shells, which give a pleasing appearance to it in winter. These walks are a trifle under 3 feet wide—the size of the space determining this—and from this the size of the beds will be easily guessed at. All are planted with bedding things in the usual way, and in spring we generally contrive to have some of the beds occupied with good spring-flowering plants, of which *Alyssum saxatile* is by far the best we have, the variegated *Arabis*, *Cheiranthus Marshallii*, and some other things are also used; but no reasonable amount of planting can prevent the raw earth from being the most prominent article during the dull winter months, so that it is to the agreeable shape and contrast with the green edging and white walk which constitute the appearance, but as a feature differing from the rest it is generally admired.

The eight small squares marked A are cubes of Box clipped to the proper shape, which is about 33 inches high, by the

same in width and thickness, and in winter these form prominent objects, and by the strictness of their forms are quite in character with the place they are in. It is right to say that the east, north, and west sides of this garden are backed by evergreens, excepting where the conservatory intervenes. A sloping bank and steps unite it to the ground below. A sundial as shown is in the centre of the walk in the garden, and the conservatory itself, though having a glass roof, has a front more resembling that of a Grecian dwelling with a parapet, &c., than that of a modern plant-house. All this I believe to be in perfect harmony with existing objects. Perhaps some one will say, More diversity of shapes might be given to the beds; to those I willingly leave the task of contriving such, and hope they will give the readers of *THE JOURNAL OF HORTICULTURE* the benefit of their inventions. At the same time, to those who have an aversion to acute angles, I may say that it was with a view to have a rigid example of the Dutch style of gardening that this set of figures was introduced. A more harmonious whole might easily have been had by curves and scrollwork, but as this belongs to another style it was thought advisable to exclude it entirely from the present example of a Dutch garden.

J. ROBSON.

ROYAL HORTICULTURAL SOCIETY.

THE Anniversary Meeting of this Society was held at the new Hall, South Kensington, on Wednesday last, the Earl of Ducie in the chair. A large number of Fellows was present, among whom were the Lord Bishop of Winchester, Earl Grey, Lord Llanover, Sir John Boileau, Right Hon. T. F. Kennedy, Colonel Higgins, H. T. Hope, Esq., &c.

The Report was read by Mr. Andrew Murray, Assistant Secretary. It commenced by accounting for the great delay which has taken place in the progress of the works in the Garden at South Kensington, which is attributed to the long winter and the subsequent strike of building workmen; but makes no reference to the time which was lost from June last year to the time when the frost set in, and during which period the building of the arcades and conservatory might have been greatly advanced. It then proceeds to state a few of the details about the sinking of an artesian well for the supply of the fountains, the erection of the memorial of the Great Exhibition of 1851, which has been placed at the disposal of the Society, and the ornamentation of the arcades by tazzas, vases, statues, and other objects of ornament.

The number of Fellows who have joined the Society during the last two years has been greater than in any similar period since the Society was instituted, these being 137, while during the two most prosperous years of the Society—viz., 1820 and 1821, the number was 625. Through this the funds of the Society have been largely recruited by their subscriptions and life payments, amounting to £13,300.

The general account representing the state of the Society before the recent alterations has worked its way into a satisfactory state.

The new charter, which has been some time in preparation, is expected to pass the Great Seal in a few days.

"The Flower and Fruit Committees have, under the superintendence of their respective Secretaries, Mr. Moore and Mr. Hogg, carried on their investigations in a most satisfactory manner, as is shown by their reports in the Society's 'Proceedings.' The Council have reason to know that these reports are regarded as valuable sources of reference by the gardening community. The Council, however, think that the time has now come when the publication of something of a more important character may be tried, and they are taking preliminary steps with this view."

Arrangements have been made for sending a collector to an interesting district in Brazil, and also with a collector already in South Africa, to collect and transmit seeds and plants to this country.

The spacious Council-room not only furnishes the Fellows with a suitable place of meeting, as well as accommodation for their minor shows and competitions, but removes any difficulty as to a hall for the delivery of lectures, and for the reading of papers on scientific subjects, should such be resolved on. The Council feel it their duty to express their gratitude to Her Majesty the Queen, and his Royal Highness the Prince Consort, President of the Society. It is only those who, like the Council, have had the privilege of seeing the time and thought bestowed by his Royal Highness upon the plans of the Garden in all their

details, who can appreciate the extent of that interest and the advantage the Society has derived from it.

Earl GREY moved the adoption of the report, which he considered highly satisfactory in every particular.

Sir J. BOILEAU, Bart., seconded the motion, which was adopted without discussion or a dissentient voice.

Upon the question of the election of the Duke of Rutland, Mr. John Fleming, and Mr. Robert Cooper, as members of the Council in the place of three members recommended to be removed,

Mr. H. G. BOHN objected to the principle upon which the names had been selected. How did the meeting know that the Duke of Rutland and the other gentlemen would accept the office, even if they were elected? He thought there was already too much of the horticultural representation in the Council, and that the private gardeners should be better represented. He (Mr. Bohn) was a member of a great many societies; but there was none to which he gave so much attention, or felt so much interest in, as this. He had done much for the Society by succeeding in keeping Chiswick Gardens in possession of the Fellows, and he hoped they would never consent to part with it. He therefore offered himself as a member of the Council, and he promised, if elected, to devote as much attention to horticulture as he had hitherto devoted to the question of the paper duties. (A laugh.) Although he had not received much assistance in his attempt to save Chiswick, the members now felt the great necessity for keeping it in their own hands.

Several other Fellows addressed the Meeting. The ballot having been taken, the scrutineers reported that, by an unanimous vote of seventy-one Fellows present, H.R.H. the Prince Consort had been re-elected President; W. Wilson Saunders, Esq., Treasurer; Prof. or Lindley, Secretary; and Mr. Jonathan Clark, Mr. Edward Rother, and Mr. George Paul, Auditors for the ensuing year; and that to supply the vacancies in the Council caused by the retirement of Henry Pownall, Esq., Robert Wrench, Esq., and Mr. Charles Edmonds, there were for the Duke of Rutland, sixty votes; for Mr. John Fleming, Clevedon, Maidenhead, sixty-one votes; for Mr. Robert Cooper, 152, Fleet Street, fifty-nine votes; for Mr. Henry Bohn, ten votes. The Chairman thereupon declared the three former, who had been recommended by the Council for election, to be the new members of Council for the ensuing year.

The CHAIRMAN then announced that Mr. Kelk had undertaken to complete the great conservatory by the 5th of June, to allow the first flower show to take place in it on that day. To look at the building the present moment that would seem impossible, but he believed Mr. Kelk would keep his word. (Hear, hear.) He also announced certain arrangements for the season, and mentioned that Her Majesty would not be able to open the Garden on the 5th of June, as promised, but that the Prince Consort and other members of the Royal Family would be present on the occasion.

Thanks were then voted to the Council and the Chairman, and the proceedings closed.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE April meeting of the Entomological Society was held on the 1st of April, the chair being taken by the President, J. W. Douglas, Esq.

The curious connection between Ants and certain other insects which take up their abode in their nests, was again illustrated by the discovery, by Mr. E. Smith, of a specimen of *Myrmecodia funesta*, a small species ofrove Beetle, in the nest of *Formica fuliginosa*, the pitiful Ant, near Erith. The same gentleman also exhibited specimens of a small Beetle, *Silvanus frumentarius*, which had infested a jar of preserved fruit of the Lichi, received from China. The species in question is often found dead in sugar.

Mr. Stainton exhibited the larvae of two species of Moths belonging to the beautiful genus *Adela*, found upon the oak; also, the larvae of a species of *Neumatois*, feeding upon the green leaves of *Ballota nigra*.

Dr. Knaggs brought forward the medical case of a child, ten years old, which had discharged a larva of some kind of Moth with sixteen legs, during a fit of sneezing.

Mr. MacLachlan announced the capture of *Stenophylax concentricus*, a species of Caddis Fly (Trichoptera), new to Britain.

Mr. G. R. Waterhouse read a notice of several species of *Monotoma*, a genus of small Beetles which live in damp wood.

Mr. Francis Walker exhibited a large case of Hemipterous insects which he had received from North America.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the cleanliness of the garden for some time will depend upon the destruction of seedling weeds at this season, it is advisable to keep the hoe in frequent use in dry weather. *Basil*, if it has been forwarded in pots or boxes may be transplanted on a rich border towards the end of the week. *Carrots*, hand-weed the beds or hoe between the rows, as also the beds or rows of *Onions*, as soon as the weeds can be got hold of. If the first main crops have failed, sow seed of the Early Horn immediately. *Cucumbers*, the early planted will now have filled the frames, and be in full bearing, such would be benefited by a good soaking of manure water in a clear state, particularly when the soil, which should always be so, is of a light and open texture. The liquid manure when applied to be of the same temperature as the bed, and care to be taken when watering not to wet the leaves. If the fruit is required to grow very large, select the best-formed female flowers near the main stem, the rest to be thinned off. When seed of any choice sort is desired, it is safest to impregnate the flowers at this season, as it is less liable to get crossed with other sorts than when left later. *Potatoes*, water those in frames during dry weather. Hoe and stir the soil between the rows of the early out-door crops. *Peas*, stop them as they begin to bloom, and sow for a succession. *Parsley*, thin the early sowing as soon as it is up. Select some old plants that are very early-leaved for seed. *Rhubarb*, cut down the blossom-shoots, as they exhaust the stool very much. *Spinach*, thin the crop as early as possible after it is up; if this is neglected it runs to seed in a very short time. Where any main crops have failed no time should be lost in getting in more seed; if the soil is moderately moistened by rain, so much the better, but it should not be waited for, because the seed, if sown when the ground is dry and warm, the first shower will be of more service than if sown after it.

FLOWER GARDEN.

Preparations should now be made for bedding out. If the beds have not been properly prepared as formerly directed let them be so without delay. Keep grass lawns neatly cut; roll and sweep walks; weed Box, Thrift, and other edgings in moist weather. Put neat sticks to the Pinks, and thin the shoots according to the strength of the plant. Self-sown annuals—the *Mimulus* family, the *Forget-me-not*, Pansies, and other such useful little things—may be transferred with balls to fill up blanks. See that runners of the Neapolitan Violets are provided for the next winter.

FRUIT GARDEN.

Continue to disbud Peaches and Nectarines. Pinch off the foreright shoots of Apricots, leaving a leaf or two at the base: these will sometimes cause flower-buds to develop themselves. Thin out, if not already done, the suckers of Raspberries to about three of the strongest; to be staked out thinly, and well mulched with manure.

STOVE.

Attend to the shifting of specimen plants. A brisk temperature with atmospheric moisture to be kept up during the day, with a decline of many degrees at night—say 75° day, 60° night. Now is a good time to commence with a stock of *Begonias* for next season's display. The following are a few showy and easily grown kinds.—*Chimabarina*, nitida, discolor, manicata, ramentacea, and Martiana. As they go out of bloom to be allowed a short rest in a rather dry house, when they may be partially disrooted, and repotted, pruning in any straggling shoots. Keep them close, and syringe frequently, when they will soon commence growing. An abundance of light, and a fair share of pot room are necessary to insure fine plants. Let them be kept a good distance apart that the fine foliage of some of the species may have full room to expand.

GREENHOUSE AND CONSERVATORY.

Many plants will now be growing fast, and, therefore, will require liberal shifts. The *Pelargoniums* that are now showing bloom, if not of a gross habit, and the *Azaleas* and *Camellias* making their wood, may be supplied occasionally with a little weak and

clear manure water. To keep up a gay appearance through the latter part of summer and autumn it is advisable to provide a stock of *Pelargoniums*, *Verbenas*, *Calceolarias*, *Heliotropes*, *Fuchsias*, &c., to be shifted forward as they may require it, and to be kept by themselves as a reserve for that purpose. Look over every plant two or three times a-week, to be turned round, stopped, and supplied with pot room and water as may be required. Take the opportunity of an early hour in the morning to give a good washing with the syringe, except the plants in bloom, the house will then become airy and enjoyable by the forenoon. Frequently clean over the borders, and remove decayed bloom and leaves as they occur, that the house may present at all times a neat and fresh appearance. Cut down and place in a cold frame the choicest *Cinerarias* for suckers, and put in a stock of *Chrysanthemum* cuttings for an autumn display. The early-flowering plants of *Primula sinensis* now exhausted to be removed to a cold pit or frame. *Asters*, *Stocks*, and other annuals might be pricked out on beds under mats supported by hoops previously to transplanting to the open ground. W. KEANE.

DOINGS OF THE LAST WEEK.

SOWED a few Lettuce seeds for succession. Sowed Onion seed for drawing young for salads to come in after the thinnings of the main crop. Planted out Lettuces on north banks to succeed those at the foot of walls, as these again will succeed those between the rows of *Potatoes* protected. Protected the first crop of *Turnips* out of doors with old hurdles and branches drawn through them, as the slightest frost when the plants are in a young state has a tendency to make them bolt into seed-stalk, instead of forming good bulbs; thinned out the earliest under protection, and sown early; white Turnip-rooted Radishes having several times to stand instead of sweet young Turnips. Thinned early Carrot-bed a little, doing well for soups; the first sown out of doors just beginning to appear. Raised the hand-glasses over Cauliflower plants, and gave the forwardest a good earthing up and a free watering with manure water, to cause the heads just beginning to come to show well and compact. Watered those planted out of doors. Watered also Cabbages, to hasten the cabbaging process and prevent them, if possible, bolting up to seed-stalks, owing to the severe check they experienced in winter. Notwithstanding this care, owing to this bolting even in small plants, the Cabbage quarter will not be so uniform as usual. Threw a little soot and lime over the young seedlings of all kinds of Greens, Lettuces, &c.; and watered with soot and lime water all the transplanted Peas, alike to assist them in growth and set grubs and snails a flitting. Used for these purposes water ranging not below 70°; ground, notwithstanding the sunny days, still very cold, owing to the clear, cold nights. *Potatoes* out of doors scarcely beginning to show. Those in pots and about fit for use, removed under the shade of spruce trees pretty open towards the bottom, so as to admit the south sun, and yet keep off perpendicular frosts. Sowed Cucumbers, Gherkins, and Vegetable Marrows, preferring to plant them out when young, instead of getting stunted and knocked about in pots, before room can be had for them, and trained and pruned *Cucumbers* in bearing, and banked up the linings close to the top of the box of those in frames, so that the box might be heated and give out its heat into the atmosphere of the box, instead of greatly exciting or increasing the bottom heat, which when too strong is apt to make the shoots spindly, diseased, and insect-covered. In such circumstances sprinkling the sides of the box generally gives enough of atmospheric moisture, and provided the top temperature is thus high enough, a very little air may be left on at the back all night, which keeps the enclosed atmosphere sweet, and gives no encouragement to insects to come to sturdy plants when established. Constant stopping and removing very old leaves in succession, to give place to newer ones not so thick but the sun may shine freely upon them, are, with sweet, light, rich soil, the great secret of Cucumber growing at this season.

On Saturday, the 27th ult., the hail, sleet, and snow came down in earnest. The ground became so covered that we might have taken it to be Christmas time. As the wind was north-east and the thermometer within a degree or so of freezing after mid-day, it was thought that precaution would be the best policy, and, therefore, Cherries, Pears, Plums, Gooseberries, and Currants were roughly covered with laurel prunings and spruce branches. In the evening the weather was milder; but before

midnight the stars appeared, and by five o'clock on Sunday morning the ground was white and crisp. Little damage, however, has been done, but I am told that in many places the Currants in Wexham and the Gooseberries have almost all dropped from the trees. Watered small trees in pots, in orchard-house nearly finished; took out exhausted Strawberry-pots and introduced new ones, dining room now very scarce. Drove a dry hand over the Muscats in bloom in second house when the sun shined. Those who are afraid they cannot draw their hand lightly enough, should shake the bunch and slightly use a very soft camel-hair brush. I prefer the dry hand to everything else in thus assisting to set Grapes freely. Of course, the pollen dust is thus easily carried from bunch to bunch, and a very few minutes will suffice to go over a small house. If a bunch should not set well after this, there is no room for self-upbraidings. Many, however, do not set well, and there is no end of grumbling, because on some sorts of fine Grapes there is only a berry here and there, which "cannot be fashed," might often be given as the true reason of the mournful deficiency—often but not always, because frequently the parts of fructification are so weak and imperfect that no dusting or shaking will be of any benefit. If a fine-looking Peach-blossom has no female organ in its centre, no care employed can ever get a fruit from such a flower. Regulated and discoloured Melons in pits and frames; and here I am reminded that I promised to say something about the training, pinching, and fruiting of Melons, at least the plan I would always adopt when the work can be overtakein.

I do not know if there is anything original in the plan, but this I do know, that I never saw it practised nor mentioned in print before I commended it in some serial many years ago; and now I begin to think the plan must be a good one, as many contemporary writers recommend the same or a similar system. One of our old friends whose writings adorned these pages, might have muttered something about "ploughing with another man's beiter," and never acknowledging the obligation; but, provided a good plan is adopted, it is but little consequence as to who was the originator. This plan, then, combining simplicity and utility, is based chiefly on two facts. First, the Melon plant sometimes shows fruit on the secondary shoots, but more generally on the tertiary shoots, and, therefore, generally these third shoots should be depended on. The second fact is, that though you early obtain these tertiary shoots and fruit upon them, yet if there is not strength enough in the stems of the plant, these fruit will either not set or refuse to swell, and when you nip them off and wait for the next joint to show, you are apt to get your frame or bed filled with a mass of small twigs, and fruit later if got regularly at all, whilst the plant is apt to gangrene and canker from such frequent pinchings and loppings to keep the branchlets anything like in bounds.

Now, to apply these two facts, we will take a supposed case. That case may be varied at pleasure, just in proportion as you fill a light with one plant, or with two or more; but the plan understood, the mode of applying it will be similar, whether you take one, two, four, or six secondary shoots from a plant. Our supposed case will be, that you take two secondary shoots from a plant. As soon, therefore, as the Melon plant has made three or four leaves or so, you nip out its point. This in a short time will cause a shoot to come from the axil of each leaf. These will be the secondary shoots. As soon as we can see them, we pick out according to our supposed case, all these incipient shoots except two, using the point of a building-knife or penknife for the purpose. The plant we suppose is put out in the centre of a bed covered by a frame or otherwise; one of these secondary shoots as it grows is trained to the back and another to the front, or, if it please the practitioner better, a little advantage is gained by training both shoots of that plant to the back, and both shoots of the next plant to the front. However that may be, fact second now comes in for our guidance. As the shoot grows every large leaf formed at every joint is carefully kept, but every young shoot forming at its axil is nipped out with the penknife again, so that these secondary shoots shall be clear of side or tertiary shoots for from 15 inches to 18 inches from the main primary stem of the plant. After that the secondary shoot is allowed to grow without any side pinching; and when it reaches within 6 inches or so of the sides of the frame, back and front, an inch or so is nipped off its point—at any rate manage it so that when stopped there will be six or seven joints at the ends of the secondary shoots, from which the young tertiary shoots in the axils of the leaves have not been extracted. After the points

of the secondary shoots are stopped, these tertiary shoots will grow with great rapidity, and most of them will show fruit at the first joint, and then being nipped at the joint above the fruit there will generally be strength enough in the plant to set them swelling kindly at once. A great deal of cutting is thus prevented. Of course, it is of importance to get as many blossoms to open about the same time as is desirable, so as to insure their simultaneous setting, and this is much promoted by nipping off an inch or so of the end of the secondary shoots, and the tertiary shoots which come behind that will be more equal in strength and flower nearly at the same time. By this plan the fruit will be chiefly congregated near the back and the front; but they may be moved a little towards the centre if deemed advisable. Of course, even by this plan in some shy kinds tertiary shoots will not always be fruitful and set their fruit, and we must stop and try fresh shoots; but in general better crops and more regular ones are secured than by the plan of early stopping and getting the place filled with shoots and twigs before a fruit can be induced to set.

In pits when grown on trellises, or when so grown from pots, we prefer taking the first primary shoot to the height of the trellis, stopping there, selecting the secondary shoots, and training the same as above. When we used to grow largely in pits, we used to stop the plants when young, select one shoot, train it to a stick or a suspended line, and disbud the side shoots until we thought we had got strength of stem enough—say when it was from 2 feet to 3 feet long; and then, stopping the point as above, allowed the tertiary shoots from the axils of the leaves, perhaps seven or eight in number, to grow, almost every one of which would show fruit.

Flower plants much the same as last week.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

LEAF LEAVES DESTROYED BY AN INSECT. *A Subscriber*.—Your young Chamaelirium plant leaves have been eaten away by that destructive Weevil or chrysothrips which, lay a cloth under the tree during the day, and then visit it at midnight when the Weevils are at work. Shake the tree, and the insects will fall on the cloth as if dead. Catch them, and kill them.—W.

STOPPING VINE-SHOOTS. *A Subscriber*.—The effect physiologically from stopping a Vine-shoot is to retain a greater amount of sap to the bunch of Grapes upon it than the bunch would have received if the sap had been allowed to be consumed in increasing the length and size of the shoot. It is necessary to leave one or two joints below the bunch; because those joints are furnished with leaves, and these leaves are absolutely necessary for digesting the sap before it proceeds to the berries for their development and ripening—in fact, the sap would not rise to the bunch in sufficient quantity if there were no leaves beyond it. This was explained in a paper on the "Science of Gardening," published in our first series, and which will appear as a volume ere long.

GRASS-LIKE WEED ON LAWS. *H. R., an Old Subscriber*.—It is, we think, the *Luzula pilosa*, or Hairy Woodrush, and your lawn must be in that case too much shaded; but it is *Luzula campestris*, or Field Woodrush, which only grows in very open places, still the only remedy is to spud it out. If your lawn is over-shaded, rendering it more open to the sunshine would destroy the *Luzula pilosa*.

MELONS AND CUCUMBERS. *J. A. P.*.—These cannot be grown to perfection in the same pit or house; Cucumbers require so much more moisture both at the root and in the air. You had better have a glazed division dividing the pit or house into two parts, growing the Melons at the hottest end. The fruits will come to maturity without impregnation; but, of course, they will be seedless.

CONCRETE WALKS. *A. P. S.*.—The thickness of the layer has nothing to do with the proportions of the mixture. Whether it be one of chalk to ten or to twenty of stones, it may be put on 2 inches thick. The top layer of lime and gravel may be composed of equal proportions. The depth of an inch of gravel for the surfacing should have no stones in it, and is best sifted on through a sieve. It is merely for colouring.

VARIOUS. *N. N.*.—Your cesspool refuse mixed with earth and ashes may be put on to the soil for any crop immediately after mixing. The sooner the better. Sprinkle your Black Currant bushes with Gishurst Compound to kill the aphides. You may put manure on your Vine-borders now though the Vines are in bloom, but do not dig so as to disturb the roots in any way. What "minute insects" are they which Gishurst Compound, tobacco, sulphur, and aphis pastilles are all in destroying? If you mean the white aphis, or mites in the soil, they do no harm—they live upon decaying vegetable matters.

GROWING FRUIT-TREE CUTTINGS IN WATER (*Deronsire Vicar*).—The plan of rooting soft-wooded cuttings in water is not at all adapted for fruit-tree cuttings, nor is it nearly so good or so easily managed as the common way for any hard-wooded cuttings.

It is with poultry as with everything else, and it may be called a truism if we say that the scarcity of the article causes

its great value. It is so; but the recollection of the fact prevents discouragement, and when it is found and known that the great consumption of the London season is supplied by the small contributions of a large number of breeders and an atom, it may afford consolation to some Alnashar who finds the golden dream of scores of chickens reduced to five or six. They will be worth more than three times their number three months later, and will make a pleasing item on the right side of the account-book.

The nearer we approach to the natural season, the less trouble there is in rearing poultry; as a certain consequence the price becomes less. That time is drawing nigh, and with its arrival the interest in such papers as this will decrease. This will probably be the last, and we will therefore repeat two or three capital rules to observe in the supply of the London market during the spring.

The fowls must be young, and there should not be a mixture of ages in strong contrast. It matters not that of fourteen chickens three should be four months, while the others were three months old, but there should be no juvenile old lady in the shape of a "tardillon" of last year's mixed up with the chickens of this. Not only is her influence bad on her younger associates, but fattening to an old fowl is like painting to an old woman—it may give an appearance of youth, but that is all; it does not make a fowl tender. Next, as in the affairs of men, so in poultry, there is a tide which must be taken at the turn to lead to fortune.

There is a period of scarcity of which advantage must be taken, and large prices will be the reward; but one day too late, is too late. The day there are more fowls in the market than are wanted, large prices are over. Let us take a case in point showing the importance of a few hours, and the alteration it makes in the value of perishable goods. The season for Grouse begins on the 12th August, and many who will not eat a bird out of season, must and will have them on their tables on that day. Any young Grouse killed on the morning of the 12th, and sent up by express on that day, will make 12s. or 13s. per brace. They will make little less on the morning of the 13th; but after that day a fall of 4s. or even 6s. per brace is common, because there is time for the arrival of birds from all parts. The tide is turned.

If, then, you have chickens now tolerably fat, and of the size, or nearly of the size, of those we mentioned in a former paper, we say, Send them at once to market. Like Friar Bacon's brazen head, we say, "Time is." If you wait till they are a little fatter, or a little larger, or if you have an idea they will be dearer, we fear we shall have to say, "Time was."

If you will profit hereafter by this homily, which we read to you every year, we will insure if your chickens come at the right season so will the price. "Time will be."

PROFITABLE POULTRY KEEPING.—No. 4.

(Continued from page 87.)

AFTER-MANAGEMENT.—When the hen comes off of her own accord, you may know all is right with the chicks. At once confine the hen under a coop (or hutch), and allow the chicks but a limited run for the first fortnight, especially guarding them from contact with wet grass—they cannot, in fact, be kept too dry. Thus care should be taken that the water-pans are shallow. Many things are recommended as the best food for young chicks, but I never found anything answer so well as crumbs of stale home-made bread; and as to the different nostrums propounded, I notice them only to condemn them *in toto*. The hen should be well fed on grain, meal, and steamed potatoes, and grass and leaves from garden vegetables daily. It is a good rule to remove the coop a few feet every day or two, so that the hen may have a fresh and dry soil, and she should have a moderate quantity of sand or light mould placed under her coop in which to bathe. In a month or so give the hen her liberty, feed her chickens with her, and they will thrive right well and merrily. I found, however, that those chicks did best where the hen, after having her liberty during the day, at night was put under a coop, she then nestled her young instead of flying on to the perch.

MANAGEMENT OF CHICKENS WHEN DISCARDED BY THE HEN.—In about eight or nine weeks, according to the season of the year, the hen will forsake her brood. Now part the stronger chickens from the weaker, and hasten on by generous food for sale. Much might be written on the all-important point of

feeding; but I shall give that course which answered well with me. I fed four times a-day—oftener if I saw occasion, or the weather demanded it. On this point no rule can be laid down, it must be left to the judgment.

1st meal.—Tallow greaves and dry barley.

2nd ditto.—Steamed potatoes, mixed with steeped oats, rice, or crushed Indian corn or meal.

3rd ditto.—Barley, tail wheat, and tallow greaves.

4th ditto.—Dry grain.

And twice a-week mashed bran.

I took care that on no two consecutive days did I feed exactly alike, for every animal thrives on variation of food. Besides the stated feeding times, all the remnants from the table and the kitchen, such as crumbs, meat, bones, and vegetables, were thrown down to them. In the winter and early spring months bullock's liver and other cheap animal offal should be boiled for both hens and chickens; put the broth therefrom when cool into their drinking-pans, and chop up the meat, mixing it with their grain, or giving it alone.

"And is this all?" my uninitiated reader may ask. "Yea, truly all, the whole secret."

I shall now suppose my chickens three months old.

"Well, my friend," I say to the poultry dealer who calls, "what will you give me for this lot?"

"Well, chickens is down, they ain't worth ne'er so much as they was last week."

"Ah, is that so? Now, though you are called a higgler, I don't like haggling: so, at a word, what is your offer?"

"Master, I can't be buyer and seller too."

"Well, my price is 3s. the couple for the smaller chickens, and 2s. 6d. for the larger."

"Then I shan't get no profit by 'em."

"They are worth it, and I do not feel disposed to take less."

"Then it's no deal."

And off goes the higgler. But wait a wee. He well knows they are worth the money, and in half an hour or so returns, pays you the sum asked with the air of a man who has done you, ties the chickens in couples, places them in his basket and departs.

And now, reader, what has been my profit?

Over 60 per cent. assuredly; and if these said chicks had been less than Pigeons early in March, I could have had 2s. 6d. each, and my profit would then have considerably exceeded 100 per cent.

"And not bad interest either," say you.

Next week I shall hope to show you how to do more than this.—LEIGHTON.

(To be continued.)

I HAVE read with much attention the interesting articles in the two last Numbers of your Journal on the subject of "Profitable Poultry Keeping;" and although fully impressed with the conviction that fowls may, with proper care, be made as remunerative as other stock, still I cannot allow "LEIGHTON'S" balance sheet to pass unchallenged. Statements to the effect that about 90 per cent. profit is to be realised by poultry keeping, and that a nett return of £25 7s. is to be calculated upon from every 100 hens kept *ad infinitum*, will, I am confident, cause only disappointment, and do more harm than good. Many fascinated, no doubt, in the first instance by such a favourable Dr. and Cr. account, might afterwards give up the pursuit in disgust when they found their calculations at fault, and how little dependance was to be placed on the dicta of those who put themselves forward as authorities in such matters.

It would have been more satisfactory had the amounts charged for "rent, management, loss, and interest," been carried out separately, as it is quite impossible to arrive at any conclusion as to the amount of interest that has been charged on the original outlay. This may appear to many a matter of small import; but when we consider how short is the natural term of life allotted to the domestic fowl, and that, in addition to the chances of death from disease and accidental causes, they cease to be remunerative, and, indeed, become (as far as profit is concerned) virtually dead, at the end of their third or, at the most, their fourth year, we should debit ourselves with a very heavy amount in the shape of interest. Any one embarking capital in some perishable article, which he knows will at the end of three or four years be almost valueless, would expect to receive interest at the rate of 35 or 40 per cent., otherwise he would be sadly out of pocket by his investment.

With these remarks, putting on one side entirely the subject of interest, I will explain why I consider "LEIGHTON" far too sanguine, and how his style of book-keeping would mislead and disappoint the unwary.

In the first place, then, it does not appear how the original stock was obtained. We read that it consisted of "every and no breed, from the common barndoor to the stately Spanish and aristocratic Game." Now, 100 nice young hens of this description, together with twelve or fourteen good cocks, would, by the time they were safely roosted in "LEIGHTON'S" poultry-house, have cost a good round sum! I apprehend he would choose young birds about a year old, the cocks, perhaps, a trifle more advanced in years, many authorities (Mr. John Bailey amongst others) deprecating the principle of breeding from chickens—that is, birds all of the same year. The whole of this lot would, therefore, have to be swept off, and entirely replaced by young birds, after they had been in "LEIGHTON'S" possession two or three years, by which time the hens would have passed their third and the cocks their fourth year. At this age they would sell for, comparatively speaking, a mere trifle, being as egg producers unprofitable, and for the table both dry and tough.

Now, "LEIGHTON" states, that "each hen will rear on an average seven chickens;" but if he sends every individual chicken to market, as appears by the credit side of his balance sheet, he makes no allowances for "death vacancies," nor for replacing the old birds, as from age they become unremunerative, and not worth keeping.

We see that the Spanish formed part of the stock, and there were, no doubt, many others of what are commonly termed "everlasting layers." Many hens would, therefore, be compelled to sit twice, and hatch broods during inclement weather, causing the average reared and actually sold to fall below seven. I will not comment on the prices obtained for chickens, but I imagine they have to be sent to market some distance—perhaps to London!

Again, "LEIGHTON" states, that "a hen will lay on an average 120 eggs; but if he parts with them all, from whence does he derive the 1300 necessary to complete the requisite number of sittings? and from what source the half dozen or so required for the young chicks in their early days?"

If "LEIGHTON" can obtain 1d. for each egg taken all the year round as a wholesale vendor he is, indeed, very lucky; but does he receive that price from a local dealer, who, having to sell again, I should not think could be so liberal in his offers? or are the eggs consigned to some London tradesman as "new laid?" In the latter case a very considerable daily expense would be incurred for carriage.

And now to conclude my remarks with the article of food, which is charged at £31 16s. "LEIGHTON" reckons on sending 700 chickens to market, and he says "the expense of rearing chickens up to the age of from ten to twelve weeks did not much exceed 1d. per head per week." Now, of course, a great many more than 700 would be hatched in the first instance, living some of them many weeks, and, therefore, costing many a penny; but giving "LEIGHTON" the benefit of every doubt, we will discard from our minds all but the 700 chickens, which at ten weeks old are sent to market. How much have they cost in food according to "LEIGHTON'S" own statement? Why, reckoning them at 1d. per head per week, £29 3s. 4d. within a few shillings of the amount charged for food. This is, be it remembered, at 1d. per head; but we are told that although not much, still that the expense *did* exceed the weekly 1d.: the extra shillings are, no doubt, therefore, this trifling excess. Now, will "LEIGHTON" say on what the 100 hens and the twelve or fourteen cocks existed during the year?—did they live entirely on "the good grass run?" At all events, they do not appear ever to have been fed; and yet I do not myself know how to make a hen lay 120 eggs and hatch a brood rearing seven chickens upon nothing but air and a good grass run.

I have, I fear, already trespassed sadly upon your valuable space; but such "loose" statements, if allowed to go forth unexplained or uncontradicted, would do but little in bringing forward the profitability of poultry keeping, but tend rather to damage the good cause, and make those who may now be receiving a very fair return for the trouble and outlay annoyed and discontented. In conclusion, then, I will briefly recapitulate the reasons for my taking exception to "LEIGHTON'S" method of furnishing a Dr. and Cr. account.

1st. No charge is made for the purchase of original stock.

2nd. No allowance is made for filling up vacancies from own rearing, and ultimately replacing the old birds.

3rd. No eggs are deducted from each hen's produce for sitting, nor for the few requisite for the young brood.

4th. No charge whatever is made for chickens or eggs being taken to market.

5th. No charge whatever is made for the sustenance of the original stock.

I trust this will be found of sufficient value to justify your giving it a place in your next Number, in doing which I know you will oblige all interested, and—E. C. C.

PIGEON JUDGING AT SUNDERLAND.

You would oblige by allowing a small space to answer the "FANCIER" as regards the Pigeon judging at the Sunderland Poultry Show, or rather to give Pigeon exhibitors some idea of the cause why the Judge was chosen in the town.

In the first place, the Society is composed of twenty-three members, twenty-two of which are poultry fanciers, and know little or nothing about Pigeons; and we are sorry to say the Pigeon fanciers of this town have not supported the Society either by subscribing or giving information, and not one of the members has been in any way connected with a poultry or Pigeon society before.

"FANCIER" has not given one word to encourage the members to carry on the Society, or amend any mistake. The reason why a Sunderland gentleman was chosen for Judge was—we applied to one at Newcastle who was recommended, but he declined. I believe "FANCIER" was also recommended, but the Secretary had mislaid the letter and had not his address, or else we think he might have been chosen in preference to one in the town. There were so few entries until the last day from a distance, and having so little time on hand, Mr. Kirton was recommended as a suitable Judge, he having been both Pigeon and poultry fancier for many years. I believe he gave his judgment to the best of his ability—he was known to very few of the Society personally. Should the Society go on, I hope Pigeon exhibitors will send their entries sooner. The Society will take every pains to prevent any complaint in future.

Five-eighths of the members are only working men who have subscribed a considerable sum independently of a great deal of labour, and are considerably deficient; and unless the neighbouring gentry lend us help, many of the members will be inconvenienced in making up the deficiency.

If there had been a surplus it was intended to be reserved for the next Show. No member would have derived any benefit except the pleasure of getting it up.

I think it would look better if "FANCIER" and others would help societies in their commencement, instead of endeavouring to knock them down. There may have been other deficiencies, being the first Show, but I hope they will be looked over, and we shall be better able to place the right men in the right place next time.—FROM THE COMMITTEE.

[This letter is sufficiently explanatory, and we only regret learning from it that there is any chance of the members of the Society being losers by the Exhibition. In such a town as Sunderland this ought not to occur; and we hope that the gentry and tradesmen will subscribe at once, not only to meet deficiencies, but to enable the Society to continue its exhibitions. Such Shows are not encouragements to a useless fancy, but promote the production of superior poultry and eggs. Enormous quantities of these are imported annually, and more would have been required from abroad if the improvement and increased fancy for poultry keeping had not been promoted by such exhibitions. We recommend the Committee to canvas the town and its neighbourhood for subscriptions.]

TURNED-CROWN PIGEONS.

In the JOURNAL OF HORTICULTURE of April 23rd, Mr. Oates says he cannot understand why I do not include the Turbit among Turned-crown Pigeons. In explanation, I beg to inform him I consider the Turned-crown as a recent innovation, and a departure from the true form of that variety (in confirmation of which, I refer him to all the older writers on Pigeons) nor can I regard it as any improvement. Fanciers have not paid much attention to the peculiar form of head of the Turbit, and

its true shape has, therefore, been much neglected. The head should be broad, angular, and flattened; the orbicular ridges much raised, and the eyes prominent. The best example I can offer is the head of a frog. The short beak, the gullet or dewlap, and the frill on the breast, are the chief properties of the breed, colour or feather being the finishing stroke; and I think the turned-crown spoils the appearance of the head just as it would do in a Tumbler or Carrier.—B. P. BRENT.

PARROT DELIGHTING IN BATHING.

I HAVE had a Parrot nearly fifteen years which, I can assure you, enjoys a shower-bath most intensely. The servant places her on the sink and turns the tap gently. Polly spreads her wings and turns herself in all directions for the grateful shower, and if the water ceases she will flutter and make a noise until it flows again. She is a large, green, yellow, and red bird, and very merry. Another and smaller bird will often follow Polly's example, but not with the same gusto the old one evidently feels.—E. H. D.

THE RABBIT (*LEPUS CUNICULUS*): ITS HISTORY, VARIETIES, AND MANAGEMENT. (Continued from page 70.)

THE ANDALUSIAN RABBIT.

THIS, the largest species known, is a native of Spain. It is bred in Paris under the name of "Ram Rabbit," because its head is large, and its forehead round, its ears large and hanging like those of the Half-lop; its throat also is large and forms a dewlap. Its fur is of a russet grey colour, and is smooth and lustrous when it is well cared for and in good health: but when neglected or sickly, it becomes curly and like wool.

M. Didiex states that this Rabbit will attain an enormous weight, even so much as from 16 lbs. to 20 lbs., and that it is the most robust race known.

The breeding of this Rabbit is receiving much attention in Paris and its suburbs, and the finest specimens fetch enormous prices. M. Millet states that he has seen 130 francs paid for a single female Ram Rabbit, and that M. Gerard, his coadjutor, paid not long ago 160 francs for a pair. Those who have this breed are so tenacious of keeping it to themselves, that it is extremely difficult to procure fine specimens without paying very high prices.

The breeding of this Rabbit is deserving of special attention, it being a wonderful producer of flesh, rendering it the most profitable species that can be bred for food. At eight or ten weeks old it ought to weigh as much as the common tame Rabbit at eight or nine months, thereby saving the expense of six months' keep, and the time and trouble in tending it; besides, the flesh is more tender, juicy, and delicate in appearance.

There is another large variety which is very similar in appearance to the Andalusian, and known in Paris as the ROUENNAIS or BULLDOG, because they have a square head like the dogs whose name they bear. Their weight is often as much as 14 lbs. In colour they are usually a light fawn, but sometimes a light grey. Their ears are long and upright, but are often Half-lop. Many of these Rabbits are imported and sold here as *Patagonians*. I think it not at all unlikely that this is a cross of the Patagonian, although it differs in appearance.

The real Patagonian Rabbit has remarkably short ears and a large round head, which when young, and seen at a distance, gives it the appearance of a cat. I do not think there are many pure bred ones in this country which, considering their size, is to be regretted.

The next on my list of large Rabbits is the *Belgian Hare-coloured Rabbit*, large quantities of which are imported, known and sold as French Hare-rabbits; but they are not hybrids as the name implies. They attain a large size, but are said not to be so fruitful as many other varieties; their ears are large, the head smaller than in either of the before-mentioned varieties, and in colour they are very similar to a Hare.—R. S. S.

(To be continued.)

BATH AND WEST OF ENGLAND POULTRY SHOW.—We are informed that entries will be received until the 13th inst., after which none can be received.

HEN CANARY NESTING BUT NOT LAYING.

I UNFORTUNATELY lost a Goldfinch last autumn, which for two years had mated with a hen Canary. I procured a cock of her own kind, wishing to breed Canaries. She has built her nest, and constantly sits in it, but without laying; and having a young mule bird, one of her own, and hearing them frequently answering one another though they cannot see one another, I wish to know whether that would have any effect and interfere with her laying and breeding.—E. M. A. L.

[I do not think it necessary to remove the mule, as the hen Canary's hearing him can hardly be the cause of her not laying. More probably it is the unfavourable weather, and that she will build again, and then lay, unless she is too old, or proves barren from some other cause.—B. P. B.]

BEES DYING—HIVES IN A BARN—PEACH CROP ON OPEN WALLS.

THE "OLD SUBSCRIBER" who wrote some time ago about a bee-hive in which the bees were inactive regrets to say they all died a few days after. The hive had a large quantity of good honey in it. When the combs were taken out there were not more than about sixty bees clinging to the combs; all were dead, but not decomposed. They were at this time a fortnight dead, and the only odd appearance about them was, that a few had under the rings of their body an appearance of a pure white substance. It did not look like mould. The combs at the lower part of the hive looked thick, and as if damp had affected them. Could it be that the hive perished from damp?

Would it be a good or bad plan to place hives in a large airy barn, having a hole made in the wall where the bees would have egress and ingress towards the south? The wall is 2 feet thick. Would it be bad for the bees to have to creep so far before gaining access to their hive?

Is the peach crop on open walls generally defective this year, from the last wet summer not permitting wood to ripen?

Some geraniums late cut down, and not yet repotted, look badly. Would it be advisable to keep them in the open air for autumn bloom when potted?

[The cause of the loss of your hive appears to have been the death of its queen. How far it may have been injured by damp we cannot determine without ocular inspection. The peculiar appearance on the abdominal rings of the bees themselves probably arose from a fungoid growth.

We have known bees do well in a house in spite of the disadvantage of having to traverse a thick wall before reaching their habitation.

The peach crop on open walls is generally defective, and probably from the cause you mention.

We cannot give an opinion about the geraniums, not knowing either their names or age.]

BEE-HIVES AND THEIR APPURTENANCES.

(Continued from page 90.)

ADJUSTER-HIVE.—Your apianian readers, the novices particularly, must feel grateful to "A DEVONSHIRE VICAR" for so ably pointing out the defects of the rather *Irish* depriving-hive, a description of which had crept into your columns, and introducing Mr. Fox's vastly superior device. At a first glance, in addition to the fixed breeding space, the peep through the back window in the sketch shows rather many openings for the escape of the heat and the queen into the super, easily remediable by corks in the one case and slips of wood in the other. Mr. Fox is also too good an apianian not to know that either for his own use or the market one completed box honeycomb, and a second partially filled (useful for feeding or a fresh start), is much more valuable than a larger box uncompleted. However, to counterbalance this we have his exceedingly ingenious mode of lowering the top to facilitate a start, and by judicious raising to tempt to an accumulation of store in the super, more certainly obtainable than by any other mode I have yet seen tried. With this passing remark I will now describe the appurtenances of the apiary, taking up first

BEE FEEDERS.—All metals, from their coldness, are objectionable for bee feeders—none more so than zinc, from the deleterious powder that collects upon its surface, rendering it an injurious

agent to supply food in a liquid state to either bee or beast; for this reason I employ it as little as possible about the apiary. I also dislike a close-fitting lid upon the metal. Bees when fed get excited; their respiration is increased, the vapour condensing on the glass damps both them and their comb. Wood would do were it not for its liability to split if cut out the solid, and leak at the seams if jointed: I, therefore, employ troughs of earthenware made for the purpose, and roughened inside. They are 9 inches long, $5\frac{1}{2}$ inches broad, and $1\frac{1}{2}$ inch deep, all outside measurement, sold by Mr. John Grant, 23, Howard Street, Glasgow. The float is of thin oak veneers; the holes bored with a hot iron into any fanciful pattern. The troughs I fit (loosely for washing-out sake) into box feeders—the one (fig. 7) is used for flat top bar-hives, is fully 9 inches long by $6\frac{1}{2}$ inches broad inside, is 4 inches high at top, sloped to $2\frac{1}{4}$ inches at bottom. There are half-inch blanks in the bottom on either side of the trough through which the bees ascend when the slides on the top of the hive are drawn. It is worthy of notice that this breadth fits equally the one-and-a-half and the one-and-one-eighth bars. The other (fig. 6) is fully 9 inches long by 7 inches broad, $4\frac{1}{2}$ inches high at back and 3 inches in front, has $1\frac{1}{2}$ -inch-square slip of wood nailed inside at the back, through which a sloping cut inwards and upwards is made to correspond with the entrance in the hive. The feeder is placed charged on the landing-board; a tap or two causes the guard to run up into it; a sip, and he is off with the news, when a general rush takes place. This feeder is used principally for round-topped hives,

Fig. 7.

Fig. 6.

and is equally easily adapted to straw hives of circular shape by a little addition being added. Take a bit of three-quarter-inch wood, 1 inch longer than the entrance in the hive. Cut a corresponding entrance in the wood, scoop out the back part to fit the straw bands, and then sprig it on to the feeder. This prevents the escape of a single bee. It is better to be wrapped about with flannel, or some warm stuff, should the evening be frosty. The feeding is seen through the glass pane in the lid of both. The bevels in the box and the openings fitted with zinc are intended for ventilation. The lids are raised with small brass hinges, and kept closed with little "hooks and eyes." Should the weather be mild (bees never ought to be fed during cold, except in desperate cases, then the last mode to be mentioned is most suitable), I have always found a strong colony absorb a larger quantity of food in less time, and, I think, with more pleasure to themselves, by being allowed to cluster from the combs upon the vessel (placed as close thereto below as possible) containing the food, than by any way I have tried, which also saves the few lives generally sacrificed by feeding in a separate vessel. Any poor fellow getting bedaubed, crawls into the cluster and is licked and warmed. I have, therefore, in all my hive-boards (see fig. 11 next week); a space cut working like a solid drawer, of sufficient dimensions (10 inches by $5\frac{1}{2}$ inches) to allow the feeding-trough to be slipped in its place below and within the hive without necessitating its being lifted. Should the combs not be wrought down their full length, then the trough must be raised on a block of wood close to them. I give my largest supplies by this simple mode.

The bottle plan, so kindly introduced to your readers by "A DEVONSHIRE BEE-KEEPER," was known and practised in that centre of bee-learning, Ayrshire, long before M. Hermann wrote. It is rather a slow process; I prefer giving a larger quantity by any of the previously-mentioned modes in the evening, and find it gone in the morning, which does not interfere with the day's work, nor attract robbers. It does, however, afford a supply to a weak colony without much excitement. I use for the purpose a clear conical soda-water bottle, on which the thatch rests nicely. My flat-topped hives have an inch-and-a-quarter hole cut with a brace and bit between the two central

bars, into which I place the neck of the bottle. They get clustering round it, and it is all the sooner emptied. The "QUERIST" afraid of the two or three bees clinging to the net is unworthy of the name of bee-keeper. The wooden block recommended by your correspondent is useful in addition, and keeps it all the more steady, particularly should the hive be flat-topped, and covered with thatch. The principal benefit of this plan, however, is for *spring feeding*. Some hives the apianian may be anxious to stimulate will stontly refuse to take the food by any other mode than the bottle—perhaps averse to move off the brood. As constant dropping will wear out the stone, so will it the stubbornness of our wee favourites. The food gets on their coats and comb; their cleanliness necessitates its being licked up, and perhaps their inborn thriftiness of character has something to do with it, too, which I never knew to be exceeded, were it not in one solitary instance—that of a farmer's wife, not a hundred miles from where I write, who, finding a large rat drowned in her cream, seized it by the tail and drew it out; but grudging the rich coating on its fur, actually licked the loathsome brute that nothing might be lost!—A RENFREWSHIRE BEE-KEEPER.

(To be continued.)

BEES DO STORE HONEY IN HOT CLIMATES.

THE editor of the apianian department of one of your contemporaries has for the last two weeks been advocating the notion, that in warm climates bees will cease to provide against "a winter that never comes!" *Barbadoes* is one of the localities especially referred to. Now, turn back a few weeks (I have not the papers to refer to), and you will find the *West Indies* specially named as the source whence our supply of honey is derived, and the rise in price of "West India honey," consequent on the failure of the home supply, is particularly stated! If bees will not store honey in warm climates, West Indian honey would be altogether unknown, instead of being the cheapest and most plentiful in the market.—APICULTURIST.

[There is no doubt of the fact that bees do store honey in tropical climates. Mr. Krapf and other travellers in the interior of Africa mention honey as being there a common article of food.]

STRANGE HABIT OF BEES IN PERU.—Mr. Sandison, son of the Rev. Mr. Sandison of this place, sends the following interesting fact in *Natural History* from Arequipa, Peru:—"A few years ago, a German got out a few hives of bees—an insect formerly unknown here. The first year he obtained a plentiful supply of honey; but year by year it decreased, until now the animals will hardly collect any. And why? Our climate is so equable that flowers can be had all the year round, and the sagacious animals having discovered this fact, have evidently lost the instinct of hoarding honey for a winter that never comes.—(*Breckin Advertiser*.)

VARIETIES.

THE MISTLETOE.—At a late meeting of the Botanical Society of Edinburgh, a paper was read by Mr. M'Nab, on "The Effects of the late Frost on Trees and Shrubs," and among others we find an interesting fact, relative to the Mistletoe—viz., that where growing on apple stocks or on the branches of *Mespilus canadensis*, it was greatly cut up and injured, but where growing on the oak or white thorn it came through unscathed, and is now quite green and healthy.

[May not this superior hardihood of the oak-sustained Mistletoe account for the especial veneration it received from the Druids? In that age of forested and undrained England, its climate was much more severe than now, and the Mistletoe we may conclude, consequently, was frequently destroyed on other trees than the oak. If on this tree it was uniformly uninjured, the Druids would at once consider it as under some especial Providence.]

RHUBARB SYRUP.—The aperient qualities of green Rhubarb, and its conduciveness to health being now so well known, its usefulness does not admit of doubt; but allow me to remark that it is best used in the form of syrup, eaten with plain bread, as are all cooked fruits, and not with pastry, especially by invalid persons who have bilious constitutions. Pastry is like strong drinks—it only serves to indulge the appetite rather than

to impart to it any real good, causing secretions in the stomach beyond their natural order. To make Rhubarb syrup is simply to cut into small pieces, simmer it over a slow fire one hour, with a very little water (or it may be baked in a jar); then strain it, and add sugar to the palate. When it is young it is like apples—unnecessary to be peeled. If sweetened with the best sugar (loaf is best), it will, if preserved air-tight, and set in a cool place, keep good for many months.”—A. HARDY, *Seed Grower, Maldon, Essex.*

SEAWEED AS A LINING FOR DWELLINGS.—M. E. Lagout, has presented a report to the Paris Academy of Sciences on the employment of seaweed, applied in layers against the thin walls of habitations, to prevent sudden variations in and excess of temperature. The marine algae, such as seawrack, may be termed a *seaweed*, which has this advantage over ordinary wool—that it does not harbour insects, and undergoes no change by dryness or humidity, provided it be not exposed to the solar rays; in that case it undergoes a complete transformation; from being brown and flexible, it becomes white and almost rigid. In the dark, on the contrary, it is unchangeable, unfermentable, imputrescent, uninflamable, and unattackable by insects. At first it has the objection of being hygrometric, but a single washing in fresh water removes the salt, and then its properties become so beneficial, that a celebrated architect has styled it the “*channel of health for habitations.*” It has been applied successfully between the tiles and ceiling of a railway station: also in a portable house intended for the use of officers at the Camp of Chalons; also double panels, the intermediate space being filled with seaweed, have been prepared for the construction of temporary barracks at the Isle of Remion. The Consulting Committee of Public Health, the Society of Civil Engineers, the Council for Civic Structures, &c., have expressed their approval of the judicious employment of the marine algae, and state that the popularisation of this process will be of great service in dwellings, especially in those of the humbler class, as it renders them both more agreeable and salubrious. It can be obtained for about 20s. the ton, which quantity is sufficient for upwards of a hundred square yards of roofing.—(*London Review.*)

OUR LETTER BOX.

TUMOUR IN HEN'S CROP. (*J. A. P.*).—If there is a wen or tumour, an operation will be needed. See what was said last week upon a case nearly similar. If the hen is three years old she had better be killed, for she will be a bad layer in winter when eggs are dearest.

GROUND OATS. (*J. M.*).—There is no particular mill used for grinding oats for converting them into poultry food. The meal of the oats should resemble that of the barley, so well known as pigs' food.

BANTAMS DYING SUDDELY. (*C. P.*).—We have carefully dissected the Silver Bantam, and find that she died of stoppage, which had apparently been some time coming on. The crop was in its natural state, and contained corn, soft meat, and grass. The gizzard was unusually full of stones; and not only the gizzard but the intestines, up to the place where the stoppage occurred. This was caused by swelling and ulceration, which allowed the passage only of the smallest possible amount of fluid, just enough to colour the feathers, and induce the belief the passage was open.

DEATH OF SPANISH HENS. (*J. Price.*).—We believe “Mother” died of old age, as everything about her seemed worn out, and her food had ceased to nourish her for a long time. We never saw a fowl with decay so strongly marked upon her. Not so “Little Mother.” She had been in perfect health until lately, and now died only from the accident of having an imperfectly formed egg stopped in the ovary, causing great inflammation, of which she died. She was exceedingly fat, and, judging from it, we should think you might diminish the quantity of food given with advantage.

GAME COCK SHOT. (*Game Cock.*).—There is no doubt that you can recover damages from the person who shot your fowl, if you can prove who did the deed. The amount of the damages would be controlled by circumstances, such as notice of the bird being a previous trespasser, &c.

HEN WITH ENLARGED ABDOMEN. (*Pentadactylus.*).—Your hen with abdomen touching the ground, and laying soft eggs, is suffering from extreme fat, or from rupture. If she had not laid we should not hesitate to say, Kill her at once; but the egg, although a soft one, gives hope. You must continue giving her castor oil, and feed her very sparingly till the swelling has decreased and she lays perfect eggs. If a week will not accomplish it we can give you little hope. She should be at liberty, but not where there is food to be had.

CHICKENS DYING IN THE SHELL. (*W. C. G., Kendal.*).—This, happening when the eggs have been set upon for about a fortnight, and being a prevailing complaint, suggests that the cold easterly winds which have prevailed for some weeks have chilled the eggs. Sprinkling the eggs with tepid water, and keeping the nests more enclosed and warmer would prevent this mortality probably.

VARIOUS N. N..—You do not state whether the swelling of the Dorking pullet's crop is hard and solid, or whether apparently full of liquid. If the former, as she appears otherwise to be in health, we advise you to keep her till she has done laying, then kill her; but if the latter, as it is caused by internal fever, and consequent excessive drinking, it is only necessary to use castor oil freely as a purgative, and to allow only a little water four times per day. She must not have water always by her. *Black Bantams* should

be very small, have bright red combs, double ones are preferred, and perfectly white deaf ears. The cock should have long sickle-feathers or streamers in his tail; both cock and hens should be close-feathered, and they need not drop their wings like Sebrights. Under ordinary circumstances *chickens* may be put up to fatten at sixteen to eighteen weeks old, but in order to have a share of the present unusual demand, we would put them up at twelve and kill as soon as possible.

GREY AND WHITE GUINEA FOWLS.—*J. M. E.* requires a cock bird of this variety, and would be obliged by being informed where and at what price she can obtain one.

VARIOUS (A. B. C.).—Your Canary will be well after its moult. Do not give it either hemp, rape, or linseed. You will derive the information you need about the *Woollywing* Comb Bar from an advertisement in our last Number, and in our No. 652, Old Series.

HAM TO PRESERVE.—A *Constant Subscriber* will be very much obliged by information how to keep hams free from the maggots known as “*Jaupers.*” Many others of our readers will be equally glad of such information.

FEEDING YOUNG RABBITS. (*Henry Treestone.*).—To obtain long-eared Rabbits they should be kept at about 60° with ventilation. At three weeks old you will find they begin eating, and should have soft food, such as fine middlings scalded with hot water and mixed to a stiff mash, also a few grey peas soaked in water till they sprout, a handful about once a-day. The does with young ones suckling should have as much succulent vegetation as they can eat—such as dandelion, thistles, marshmallows, wild parley, and the refuse of any salads; but do not give too much at one time, or they waste it. Well-bred Rabbits seldom require a cap, but at times some of the best-bred will require them. Many fanciers think stitching better. There will appear a drawing of a cap, and from which you will be better able to make from than by a description.

CHINCHILLA RABBITS. (*J. C. E. C.*).—In reply to your queries respecting the Chinchilla Rabbit. A doe Rabbit is fit to breed at the age of six months. In their wild state they breed at five months. Their skins, to be of the greatest value, should be taken off in winter, and in cal-ur are supposed to be in perfection at seven to nine months. To answer your other question as to the weight is difficult. Some strains are much larger than others. We have two does, each of which weighs 9 lbs.; but from 5 lbs. to 7 lbs. is the general weight of full-grown specimens.

ATTACHING BARS AND FIXING WINDOWS IN STRAW HIVES. (*O. P.*).—The simplest and most economical mode I have tried of attaching bars to straw hives, either square or circular, is to have the two top-bands wrought double—that is, two outer bands being confined round the upper ones on which to rest and fix the bars. A further improvement I found to be forming a frame of four pieces five-eighths wood, equal in length to the external dimensions of the hive, and in breadth to the double bands, joined at the corners by cutting half the thickness from the upper sides of the end-pieces and under of the others. On this frame range the bars at the required distances, and retain in their places with short brass screws. For round hives the frame or ring is cut out of the solid, and must therefore, to prevent splitting, be at least 2 inches broad, and the thickness increased to an inch or two half-inch rings joined with the grain of the wood reversed (see page 72). Instead of placing over the bars a thick clumsy crown-board, which, besides impeding the ventilation, on its removal disturbs the whole colony, exposing the operator to an united attack, have the sides of the bars grooved, and the spaces between filled with slides working therein. The removal of a bar is easily effected without risk by placing over it and its slides a slip of glass. On the slides being drawn the apiarian satisfies himself as to the straightness of the comb. A few puffs of smoke both sides cause the bees to abandon it, and a spare bar or comb-frame takes its place. These frames are fastened to the hives with long screws introduced through the under side of outer bands. On their withdrawal the frame, with the entire contents of the hive, can be transferred to a fresh hive. To effect this, or for the transference of single bars of either honey or brood to strengthen weak colonies, the bee-keeper must foresee the great advantage of working a uniform size. Windows are easily introduced by cutting out a portion straw bands, and fitting tightly in the space a frame containing glass and a shutter. To prevent its starting, a thin card can be tacked on it above and below, and slipped round between the bands and tied at the sides. (See Cut.) Square hives possess the advantages of space for a large window and bars of equal length, but a rear interior to the circular or octagon form for concentrating the heat—a matter of considerable importance for the production of early brood.—A *RECKLESS BEE-KEEPER.*

ERECTUM.—At page 72 read the sentence, “They are fitted with eight bars, six of them 1½ inch wide. The remaining two 1½ are placed one at each end. These, every bee-keeper knows are devoted exclusively to honey, and are therefore better the broad size, instead of ‘*than*’ the broad size.”

LONDON MARKETS.—MAY 6. POULTRY.

With the exception of ducklings, we have no change to note. In their case, an exorbitant price has killed the demand. Judging from all previous years, we think we may say the present prices will not last much longer.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 64.8° and 42° respectively. The greatest heat, 86°, occurred on the 17th in 1833; and the lowest cold, 25°, on the 15th in 1859. During the period 145 days were fine, and on 93 rain fell.

“LET THE WINE BE RARE, THOUGH SCANT IN QUANTITY.”

N the *Cornhill Magazine* for this month there is a piece of poetry entitled ‘Sold;’ and I might perhaps have headed my paper thus, for it has to do with a process to which—using that word in

vulgar parlance—I have more or less submitted to in common with most amateurs for many a long year. For I wish now to speak of a series of annual at-

tacks, in which raisers of and sellers of flowers are the victimisers, and the amateur florists the victims; and as I see symptoms that the latter much-enduring race are at last “kicking in the traces,” I may, I hope, without offending any one, say frankly what I believe to be the general feeling of florists on the points to which I allude, and suggest how much better policy it would be to adopt a different course.

Any one who takes the trouble to read the advertisements in any of the leading floricultural journals will find that, every autumn, there come out a series of flaming announcements of some of the most wonderful novelties that ever were seen; and as spring catalogues begin to bud, a fresh crop of these startling introductions makes its appearance. Pelargoniums, Cinerarias, Fuchsias, Dahlias, Pinks, Hollyhocks, Verbenas, Roses, Chrysanthemums, annuals, and other flowers of a similar class, are the subjects of these high-sounding praises. We read the descriptions—nothing can be more precise; and amateurs, according to their means, invest their floricultural capital in them. They do not come out by twos or threes—no! there must be eight or nine Fuchsias, a dozen Verbenas, and so on. Flowers are there which have passed through the ordeal of a close scrutiny, and others that have never been through any ordeal at all, save the affectionate not-too-severe criticisms of their tender parent. Well, they are taken home. Oh, how carefully watched and tended! As blooming time comes on great is the interest they excite. Will they equal what is said of them? One begins to open—well, it don’t look much. We see, however, it cost its 5s., or 10s., or 15s., or even a guinea; so we are unwilling to acknowledge its deficiencies and to confess to our discomfiture:—it is only a first bloom, the next may be better. Alas! it is worse: and out of the dozen that we have received, perhaps three or four may be retained, but no more, and we inwardly confess ourselves—shall I say it?—“sold.”

I have now been a florist for twenty-five years; and if I were to put together all the series of hot and cold fits to which I have been subjected, I am sure it would equal Dr. Livingstone and his African fevers. Such a

state of things is not creditable or pleasant. But I believe that the fault does not lie altogether on one side. There is an insatiable curiosity on the part of growers for something new, and it is hardly in human nature to resist the temptation of satisfying it; while there is the almost pardonable weakness in raisers of believing that their own flowers must be the best. Their eye has been accustomed to a peculiar strain, and they do not think anything out of that can be equal to theirs; and hence the offence is committed.

Is there no remedy? It seems as if the public begins to think that there is, and that they are determined to try it. The demands that a flower should satisfy the requirements of the Floral Committee are becoming more urgent; and growers and raisers of flowers will, I hope, soon see the advisability of submitting their productions to its decision. It is by no means sparing in its certificates and labels where there is any merit; and I think, that if a flower is really worth sending out, it will receive either the one or the other from that Committee. It is so constituted, too, that, unless on some rare occasion, justice is pretty sure of being done. Let, then, the amateur hesitate before he purchases anything that has not obtained its sanction.

It may be said to this that many raisers live at a great distance from London, and that others would hardly be able to risk the expense of sending a bloom of a florist’s flower so far. But surely the communication throughout the country is so cheap and rapid, that when we find one grower sending up from Edinburgh a box of Pansies to the Botanic Society’s Show, this will hardly be a sufficient excuse.

By-the-by, I see the Scottish Pansy Society has very wisely adopted a sort of Floral Committee of its own, to which all flowers are to be subjected, and I believe nothing is to be sent out that has not passed that ordeal; and as Scotland is now one of our chief places of supply for novelties, this step cannot but be desirable for both the raiser and the grower. I say the raiser, for I happen to know in one case that the price of a set of flowers has this year won just half as much again to the firm which is sending them out, on the ground that their having obtained first-class certificates at the Floral Committee had enhanced their value: and desirable for the growers, for it insures to them that their money will not be thrown away.

There is, however, a practice of freighting the vessel which contains three or four good varieties with as many more that are utterly worthless, the good qualities of the former being regarded as something that is to make up for the defects of the latter. This is a positive injury to the amateur, who is cramped, perhaps, for room, and who gives up some of that for things he will have afterwards to throw away. I see that one of the leading London firms is advertising a great reduction in the price of novelties—almost, in many instances, to one-half. I believe they would have acted much more wisely if they had kept to the former price and reduced the number to be sent out.

As the taste for horticulture is spreading, we may expect that those who devote themselves to raising seedlings will increase in number: and consequently the evil, if not checked, will increase. We should think it very hard to be obliged to put up with two or three bad eggs because the dozen had to be made up; and why should we put up with a like absurdity in flowers? It all arises from greediness. The grower is greedy, for he wants to have ever so many new things each year: the sender-out is greedy, for it is very tempting to be able to get double or treble the price for a plant because it is new.

I say nothing of the raiser, because he oftentimes knows but little about the matter, and is only the unconscious victim in the hands of the person who takes these little matters off his hands. We must, then, agitate for a reform. Great changes have taken place. The time for letting out *Pelargoniums* at five guineas has long since gone by. Even the guinea and a half has fallen to a guinea. But, as I have said, the reform we want is not so much in the price of the flowers as in their number; and the nurseryman who will set his face against the present system will indeed be a public benefactor.—D., *Deal*.

PHENOMENA IN THE CROSS-BREEDING OF PLANTS.

[HAVING received the following letter from Mr. Darwin we forwarded it to Mr. Beaton, and now publish it with his reply.]

"Will Mr. Beaton, who has made such a multitude of most interesting observations on the propagation of plants, have the kindness to state whether varieties of the same species of Composite plants frequently cross each other by insect agency or other means? For instance, will any of the *Cinerarias*, if kept apart from other varieties, breed true? but if standing near other varieties, will they generally, or almost certainly, produce a much greater diversity of coloured seedlings?"

"I saw an allusion by Mr. Beaton to this subject in THE COTTAGE GARDENER of last year with respect to *Zinnias*; and from this allusion I infer that *Zinnia* sports much when kept separate.

"As I am begging for information on the natural crossing of plants, I will likewise venture to inquire whether the great raisers of *Hollyhocks* find it necessary to keep each variety far separate from the others for raising seed. The late famous horticulturist, the Hon. and Rev. W. Herbert, when I visited him at Spofforth many years ago, remarked that he was much surprised (considering the structure of the flower and the relative periods of maturity of the pollen and stigma) how true some sorts of *Hollyhocks* bred, even when growing close to other varieties. I have found this to be the case with some of the varieties, and cannot understand how it is possible. Mr. Beaton might, if he pleased, write an article, very valuable to physiological botanists and of some practical utility, on the natural crossing of varieties. He might indicate in which genera crossing most commonly occurred, and in which it seldom or never occurred. For instance, I have observed Sweet Peas during several years and believe that they never cross; and it is not easy to make an artificial cross, though I succeeded at last, but got no good in a horticultural point of view.—CHARLES DARWIN, *Durp, Bromley, Kent*."

I am not aware that any two species of Composite plants under cultivation have ever been crossed by man, or through the agency of insects. Mr. Penny, who first broke down *Cineraria cruenta* in the Messrs. Young's nursery at Epsom, said he got it to cross with another species, I think, from Tenerife. It is more in accordance with the experience of cross-breeders, however, that superior cultivation induced the disposition to vary, as in the *Dahlia*. The Swan River Daisy, *Brachycome iberidifolia*, is the last instance we have of this in the garden; while *Zinnia* is the last variable Composite plant that has been turned into double flowers, so called. This last change is said to have been effected in India; and if it is really so, the effect may be ascribed to climate more than to high cultivation. We know the Port Natal *Gladiolus* (*natalensis* or *pittacinus*) could not be crossed here, or on the Continent, with any of the old Cape species or their seedlings; but in Australia, at Sydney, the cross was easily effected—*Gandavensis* being the first seedling of that cross; but as soon as that cross got into the hands of European cultivators they experienced no more difficulty in pushing on their crosses in the strain of *natalensis*. These are three recent instances of the undoubted influence of cultivation and climate over genuine wild species. For the first seven or eight years of high cultivation the Swan River Daisy kept to its original colours—blue and white, then varied into lilac and purple and minor shades. When a flower or species thus varies from the effects of cultivation or climate, the variation is also variable in degree. Some of the varieties produce themselves quite true from seed from the first; others,

on the contrary, take some years before the colour or habit is "fixed," as gardeners say when a variable plant comes true from seeds after sporting for some years; and some never get fixed, or have not done so yet, and *Zinnia* is an instance of it. In all these instances some people attribute the changes to cross-fertilisation; they have been crossing their flowers, and they have seen results, and account for them that way, deceiving themselves. But those who have studied and experimented on the effects of cross-breeding, as against the results of the effects of climate and cultivation, have long since arrived at the conclusion that crossing has no power on fixing any two plants which naturally sport—that is to say, on fixing a seedling from their union combining so much of the qualities of each of the parents as is generally the case when two permanent kinds or species, which always reproduce themselves or their like, are united. That conclusion strikes at the root of the fallacy which obtains in respect to the best means of improving all our domestic fruits; and yet crossing is an element of great value in improving flowers and fruit, which seems a contradiction, but is explained thus:—Some seedlings from plants that have been crossed for a generation come quite true from seeds, some half true, and some on which no reliance whatever can be placed, or, in our language, they always sport from seed. On those which this sport-crossing has no effect—such, however, as come half true and half sport-crossing—there is a chance of an intermediate condition, and those merest varieties which come true from seeds crossing is just as effectual with them as with two genuine wild species. One would think, therefore, there were no natural limits or difference between a species and a permanent variety—that is, one which comes true from seed, like the large-flowering variety of the *Mignonette*. In practice there is no landmark whatever between such a variety and a wild species. The garden *Cinerarias* are sporting plants as much as the *Dahlia*, yet among a thousand seedlings of each, one may turn up which will come half true from seeds, and when one finds such a seedling in any of the sporting families of common plants he keeps it for a breeder, even if it were the worst-looking in a large batch of seedlings. The way with *Cinerarias* more than with most plants is this—by a careful selection of kinds under high cultivation one gets a superior strain, as we say, or superior flowers, which, although they will not come true from seed, will produce more good seedlings, or less bad ones, than an inferior strain: therefore, if a good flower or good strain of *Cineraria* is exposed to the pollen or influence of a bad strain, the good breed is immediately deteriorated in the sporting offspring. I am not aware that any of the garden *Cinerarias* come true from seeds, or if any of them could now be crossed with the nearest wild species. The only Composite flower on which I ever spent time is *Dahlia scapigera*, the pretty little lilac dwarf *Dahlia* with small shining foliage, and I think I can venture to assert that in our climate it is impossible to cross it with any of the garden *Dahlias*. It is just the same among *Primulas*: notwithstanding the freedom with which *Auriculas* and *Polyanthuses* will sport among themselves, you cannot drive a seedling from all their races by the pollen of their nearest kindreds. When *Primula Palinuri* and *sinensis*, which were introduced the same year (1816) came into general cultivation, I was initiated into the mystery of crossing flowers, and these two were of the number which raised the hopes of the cross-breeders, particularly *Palinuri*, which, to a common observer, is nothing beyond a huge *Auricula*; but none of the wild species of *Primula* would touch each other or the garden varieties. Then you see no end of sport seedlings in the *Dahlia* and in the *Primula*, in two distinct species of *Primula* and two botanical species of *Dahlia*; and yet the rest of their families obstinately hold aloof from each other, and from the sports of their respective kinds.

The old *Hollyhocks*, or some of them, were fixed varieties; but whether they were so fixed from the first, or induced to fix by a long course of culture by propagation of the roots we do not know, but the fact is well known that some of the old kinds would come true from seeds. A long course of one uniform culture renders some plants barren altogether, as *Crocuses*, and a long period of years intervenes between the birth of some seedlings and their coming to the age of puberty—to the age of producing seeds, although they may have flowered from the second or third year from the seed. *Ribes sanguineum* flowered six or seven years before it began to seed; and Dr. Herbert records an instance in which a certain seedling bulb flowered fourteen years before it produced pollen or would seed.

"The relative periods of maturity of the pollen and stigma,"

seems to have been a wise law from the beginning for the preservation of the kinds of plants in their generations, for there is not a flower in a thousand that is fertilised by its own immediate pollen. The pollen is in advance of the stigma in the great mass of flowers, and the pollen from another flower on the same or neighbouring stalk is the fertiliser. And here another wise law is in operation: When the stigma is ripe it is exposed to the influence of the pollen of all the plants of its own kind which may be growing near it; and the law is, that the pollen of the flower, or of the plant which is the strongest or best developed, takes the lead in fertilising the stigma, and at the same time is able to neutralise any effects that may have been produced by an inferior pollen, or pollen from a weaker flower or sickly or stunted plant—a thing which can be proved any day in the summer by dusting the stigma with its own and sundry pollen, when one kind of pollen only will take effect. And that proves two things in addition to the proof that the best pollen takes the lead—proves superfecundation to be impossible, and also proves that the ideas of physiologists are not according to Nature as to the progress of the pollen to the ovary. They say the pollen passes through tubes of extreme tenuity to the oviducts. If that were so, and more than one stigma supplied the necessary passage, more than one kind of pollen might find access to the oviducts, and more kinds than enough would fertilise the embryo seeds, and superfecundation would necessarily result.

In the instance mentioned by Mr. Darwin of Sweet Peas never crossing, they belong to a class of flowers every one of which must, of necessity, be fertilised by its own pollen in the great majority of instances. The carina, or keel, or lower petal in pea-shaped flowers is, in reality, two petals joined at the edges. The joining is the keel, the ends of these two petals lap over or fold into each other, forming the imaginary bow of the boat; the stamens and the pistil are compressed within the folds forming the bow, and fertilisation is effected in the dark, and the stigma is perfectly safe from the intrusion of foreign pollen: therefore, no garden Pea can be naturally crossed more than a Sweet Pea, unless, indeed, a strong bee with other pollen on his legs has been struggling to get at the nectar in the stern of the boat. Some of the varieties of the garden Pea may be crosses resulting from a struggle of that kind, but the great majority of them are the results of the sporting tendencies of the plant itself. This is the true cryptogama of Nature, of which, however, there are many more perfect instances. The great bulk of the order of Bellworts, or Campanulas, are real cryptogams, their fertilisation is effected in the dark before the flower expands; but the Wheat might be said to be the most complete cryptogam of all the common plants. No kind of Wheat has ever been naturally crossed and never can be. When the Royal Agricultural Society talk about the Wheat being in blossom, they are just one month behind Nature. But what they and the bulk of the country people take for the flowering of the Wheat, is one of the most beautiful contrivances in Nature as means to an end, a departure from the law of Nature, as it were, to preserve food for man. The Wheat is in full flower, and the seed is fertilised while the ear is yet in the folds of the sheath before the Wheat is in ear. At that period the anthers might be said to be sessile, or to have hardly any length of stamens under them; but as soon as the pollen is shed, the husk of the anther might rot in such close confinement and endanger the safety of the staff of life now having just received vitality. To prevent famine for lack of Wheat, however, Nature alters her common process in this matter. As soon as the anther is emptied of the pollen the stamen begins to grow and to push up the husk of the anther away from the embryo seed; and by the time the ear is seen the husk is well high out of the scales which enclose the seed, but stops not there nor till the husk is dangling from a white thread far off from the entrance to the seed-case, and when all dangers are thus provided against, the farmer congratulates himself if the weather is propitious for his Wheat in blossom!

I do not know an instance "of the natural crossing of varieties." My own experience of variable plants was given last week, and I do not exactly comprehend what is meant by natural varieties, for all the so-called varieties in cultivation have been artificially obtained either by a change of cultivation, or by crossing with pollen such kinds or species as would sport from seeds under cultivation. These kinds I call variable plants, their own progeny being constantly variable in aspect, and just as variable when the pollen of another flower is applied to them. It is a difficult thing for a gardener to see or comprehend the meaning of what botanists call varieties, or natural varieties of

plants, because there is no limit, or sign, or any other indication in their outward aspect to distinguish them from the oldest species on record, and there is nothing in the botanical structure of even a variable seedling to distinguish it from a genuine species. Professor Henslow proved that point long since in his comparative anatomy of a cross-bred Foxglove, or some such plant. I do not know of one plant that is a cross between any two plants in a wild state. I do not know that any one has obtained a true cross in any of the pea-flower plants—papilionaceous plants, nor yet any reliable cross among all plants of the Composite order. I know one thing on which many, if not most gardeners, put a great stress or value in knowing—that is, the conditions under which plants that are fit subjects for garden decoration are found in their natural habitats; but that knowledge is of little practical value, or may prove to be a hindrance to the proper cultivation of particular plants for some time, and yet might be the means of suggesting why and how plants may be, or have been, induced to cross in a wild state, or have sported into variations without crossing. That one thing needful is proved to be of so little value by the well-known fact that very many garden plants, or their immediate ancestors, did not, and do not at the present day, occupy those regions in the wilderness which were best suited to their natures. Their positions or habitats, as we say, are more often the result of necessity, not of choice. A plant that would thrive and be luxurious on the sea coast, on the plains, or in valleys in beds of alluvium, or in the shelter of high ridges, or precipitous rocks, can find no foot room in such luxury from the natural competition of more powerful neighbours, as was the case not many ages since among ourselves in the midst of civilised life; and from this competition the weaker plants must always go where they can vegetate and live a quiet life without rank or luxury—in the highways and byways of the savage wilderness, and in time they become the alpine and sub-alpine species of that part of the world from sheer necessity. They may even become sterile from a long course of the starving principle. But now recover one of them from impending fate, give it to a florist or a fancy gardener who is above the vulgar prejudice, in his belief that all plants in a wild state must, of necessity, occupy the places best suited for their natures, and he will soon tell a different version of how the matter really stands, and might have stood in the wilds, if the plant could get admission to those parts for which its constitution was formed to enjoy. The plant is found to be a luxuriant grower, not at all like a mountain plant, or a rock plant, or ridge or the bare-places-of-the-earth-kind-of-looking plant one might expect from the description of its habitat. After a round of cultivation has brought it to that point from which it fell, from the competition in foreign parts, it begins to seed; and if it, or any of its seedlings sport for joy, why, a new race is born into the world, as has been the case at every revolution of the order of things since the world began to be clothed as it is now; or if it comes true from seeds, another flower of the same kind which have been already civilised, as it were, may cross with it or by it, and a generation of gentry is forthwith on the stage of the florists, or of that of the competition tent. But suppose the wild plant had found a place suited to its nature in the struggle with stronger plants, and that it inherited the property of sporting or of crossing with another, may we not believe that a new plant, or new race of plants might thus result by such natural means, as by the artificial process of the home cultivator? That is as far as the experience of gardeners and cross-breeders can account for natural crossing in a wild state.

The artificial crossing of pea-shaped flowers is easy enough. All that the operator has to do is to split open the bottom part of the keel-petal or united petals with the point of a pin: that relieves the stamens, which may then be extracted, and the pistil is free also to receive foreign pollen. Mr. Knight made an experiment for getting early Potatoes to seed by planting them on a ridge, and when the plants were ready to bloom he washed away the soil of the ridge to prevent them making young tubers, and so force the whole strength of the plants or roots into the stems and foliage to see if that would force them to seed. Another form of that experiment is applicable to all bulbs and tubers which form roots on the flowering-stems, as the Japan Lilies and others do. Pot such bulbs or tubers with the neck of the bulbs just at the surface, and when the stem is an inch or two put an empty pot over it, introducing the stem through the hole at the bottom of the pot, then earth up the stem, and when it roots and fills the upper pot separate from the bulbs, then cross it.

D. BEATON.

VINES REFUSING TO BREAK.

I HAVE in my late house of Vines three Vines that I cannot get to break, except at the bottom of each stem. When I entered on my present situation in July they had been under the care of a labourer, and had been scoured, and bore little fruit. When the pruning season arrived, which was on the spurring system, I cleaned all the old bark off, and washed them in a mixture of soft soap, sulphur, and cowdung—a mixture always used at Trentham for all the fruit trees. My early house, which I have treated the same, has a noble crop of fruit on. I may also add that the roots are outside, and have been covered with horse-litter to the depth of 14 inches all the winter. When I took the litter off, about the middle of the month, I found the border wet, but the roots are good.—H. H., *Lancashire*.

[If the tops of your Vines will not break now we should judge that they must be dead, and we should judge that they have been killed by exposing them to frost after peeling their bark off, or that in washing them you used the paint in too warm a state. You give us too few data from which to judge; but as they are breaking from the bottom, either cause would produce the result. Are there no marks of mice or rats gnawing the stems above the place whence the young shoots are now coming? If the upper portions of the rods are dead, you cannot do better than replace them by some of the young shoots from their base.]

A GLIMPSE OF WOODHALL.

(Concluded from page 79.)

THE kitchen garden is large and beautifully situated, well sheltered, and the walls extra well supplied with fine fruitful trees. Beyond the walls shrubs and trees had suffered rather more than in this exposed place; but inside there was a great difference. Apricots seemed scarcely touched, and well stored with prominent fruit-buds, whilst ours had shrivelled up or dropped, though the wood-buds remained. Peaches, too, on a wall were a picture, for its fine trees seemed little injured; and though on cutting some shoots the heart was rather brown, Mr. Beale thought they would manage to grow and bear their crop. A Pear-wall, the shoots trained horizontally, some years before had the spurs thinned and gradually removed, and young wood tied downwards over the main branches, and these were bristling with flower-buds, though Pear-blossom is extra thin in many places this season.

I noticed an underground spacious chamber for all root crops where there is no danger of frost entering. A commodious stair leads to the entrance, but light is obtained and the roots put in through a trap-door on the ground level. Potatoes, Carrots, Beets, &c., were in excellent condition. Mr. Beale praised very highly the Pine Apple Beet for its rich colour and extra saccharine properties. The Mushroom-house was on the old principle of Oldhere, with wooden shelves, and the lower beds next the ground were seldom used, as the shelf-beds were more thoroughly under command, and plenty were obtained from them by successions. Some bushels might have been gathered that day. I noticed no peculiarity except that the surface of the beds was rather loose, but Mr. Beale stated they were not so firm as he generally had them.

The whole forcing department was next to perfection. A long pit of young Pines heated entirely by fermenting material within, such as tan, and dung linings without, looked very well, having been carried through the very severe weather without suffering in the least. The plants inside were all nice and dry, not wrapped in moisture and cold vapour, as they frequently are in pits heated by dung at that season. This was much owing to the closeness of the brick walls. They had originally been pigeon-holed, but Mr. Beale had the holes filled up, and now with the dung banked up to the top of the walls, the enclosed atmosphere was dried as well as heated, and air could be given more freely in favourable weather. The fact bore out what has several times been stated about heating by dung.

A little above this is a long range of span-roofed houses or pits in three divisions, but which can be all heated at once, or one or two only, beginning with the end next the boiler. If not all new it has been remodelled by Mr. Beale. The side walls are from 3 feet to 4 feet, with ventilators in them for side air. In one side the sloping roof each alternate light is made to slide; and as the lights are heavy, a stout iron pin with a chain attached

goes through them into the wall-plate to keep them secure when close or open. A few inches at top are found sufficient for all early crops. The height to the ridge is 8 feet, width of house about 11 feet. A pathway down the middle divides it into two beds. There are two pipes on each side for top heat, one next the outside wall, and one above the wall of the path, both on the same level; and one running back under the bed, with a little fermenting material, gives enough of bottom heat for cucumbers, melons, &c. A peculiarity is a stout wooden shelf immediately above the pipes next the passage, and which in such a position, independently of the non-conducting properties of wood, becomes nicely warm and furnishes a good platform for a few ornamental plants. On the 8th of February the boards were mostly filled with cutting-pots of Verbenas, &c., doing nicely. Cucumbers were put out in some of the beds, and there were some fine Orange plants coming into bloom for the conservatory.

Higher up still on the sloping ground were a range of Pine-houses. These had originally been very wide pits, covered with huge sashes some 16 feet or more in length—a fine benefit to move up and down for air, and to take off when anything required to be done! The sashes are retained, but the back wall has been removed, except what was wanted for a curb for the Pine-pit, and the house has been widened so as to permit of a wide pathway behind, covered with a short-hipped glass roof, by which air is easily given. The middle division has been converted into a stove for plants, with massive slate platforms, as more Pines were grown than were wanted. The Pine plants were strong and stubby; some swelling, some showing, and many presenting that look that tells the gardener that they would yield their fruit in regular succession. The smooth Cayenne seemed a great favourite, and the plants were very fine. I find several gardeners are becoming greatly in love with this kind. A good judge told me lately that the fruit had an aroma of its own. It is certainly more pleasant to work among than the hard prickly gentry.

On the brow of the slope stands a splendid range of vineries, some 16 feet or 18 feet wide, and lofty in proportion, the roof coming low down in front. These houses are heavy, with immense sashes in the old-fashioned way; but the Vines were pictures. The later vineries had the floors covered with bedding plants. One house or more was filled with Scarlet Geraniums in small pots, soon to have a shift into a larger. Each pot had a large cutting put into it in autumn—a good plan where such room can be afforded. When Mr. Beale has the new flower garden in full working order, most likely he will have to economise room, too, in winter.

The early vinery was a fine sight. The bunches were within a few days of flowering on the 8th of February. The Vines had been spur-pruned, and I did not notice a shoot without its bunch. The crop, therefore, would not only be fine, but regular and equal, and the Vines were in the best possible condition. As far as I recollect, the Vines are planted inside, but the roots go out into a wide border, with a fine slope to the south. How then was the border treated? Much in the way recommended by Mr. Bailey in a late volume. Early in autumn some rich dung is placed on the border, that the virtue may be washed in by the late summer and autumn rains. Early in autumn—at least before the ground loses heat by radiation—a good layer of fern is thrown over the border. Later some long litter is added, and hurdles thatched with straw are placed next the front wall of the house, and in front of them the border is rough-thatched, so that much of the rains of winter is thrown off. The mode of covering will not throw much heat into the soil, but it prevents the heat accumulated in the summer escaping at all freely, so that the roots will be in a comfortable position, and ready to meet the demands of the expanding leaves and swelling bunches. One peculiarity of Mr. Beale's system, and one worthy of being noted, is—in his early house *he never moves the covering until the Grapes are coloured*, if not mostly cut. Then the border gets its fresh dressing, as alluded to above.

Another peculiarity (or nearly so, for I noted the same thing in a short description of the Poles, the residence of Robert Hanbury, Esq.), is—that the heating-pipes are on the same level. In these vineries there are five four-inch pipes somewhat regularly distributed over the width of the floor from the pathway to the outside front wall. That is the number in this fine early vinery at any rate. Four of these pipes are flows, and one is a return. So far as the hand could judge, all were as near the same temperature as possible. When less heat is wanted

than such a number of pipes would give off, the application of a valve shuts off the circulation from two pipes, and confines it to two flows and one return. The pipes from the part where they communicate with the boiler, or main flow, rise slightly, perhaps 2 inches or 3 inches to the farther end, and an open air-pipe there prevents all accumulation of air. The boiler is supplied from a cistern near it in the back shed. The attendant on the fires has to see that the cistern is always supplied with water. At the highest end of the pipes a very small tap is fixed, by turning of which as he goes through the houses, Mr. Beale may know in an instant if the boiler and pipes are properly supplied, as, if there is water in the cistern above the boiler, the water will issue from the small tap. A very handy check is thus always ready. Mr. Beale has done almost the whole of the heating himself; and after the usual packing at the heads of the joints, he fills them entirely with Portland cement, and so far as sound joints can tell, it would seem that nothing could answer better.

A very great advantage connected with this garden is, that from a reservoir of water on an elevated mound, and by means of pipes along the walks, and strong plug-taps at suitable intervals, and a fair amount of hose, all the wall trees can be washed, and the growing crops watered, with but little labour. The water-barrow must, therefore, enjoy something like a snug sinecure.

Mr. Beale's comfortable house—the main living-rooms being half a story above ground—stands at the north side of the garden, a small flower garden in front separating it from these vineries and their range of back sheds. In these sheds are the rooms for the young men—the floor somewhat sunk below the ground level outside—almost the only thing at Woodhall suggesting an improvement, as independently of the sunk floor, hardly a direct beam of sun can enter windows facing the north—an objectionable feature, whatever other advantages these rooms may and do possess. In these rooms Sir Joseph Paxton lived, and there, too, is the very bed on which he slept when a young man, and wielding the shovel and poker in attending to the furnaces of these houses.

Very simple things often show us what changeable, inconsistent creatures we are. I had the pleasure in crossing the park to the kitchen garden with Mr. Beale to meet the youthful proprietor of this fine demesne, and could not help wishing that son and sons to come might be as distinguished as their sires for those sterling qualities and unobtrusive benevolence that have made the Abel Smiths an institution of the county. Anon I began to wish, that when the period came when these noble commoners should be enrolled among the peers of England, the popular well-known name might still be retained, as in the case of Lord Herbert of Lea, and that if lords there were to be, it might be Lord Abel Smith of Woodhall. Ere long we even began to doubt whether such added dignity might be the best of all compliments, and if we could not sing we could have chorused the independent spirit-breathing lyric of Burns—"A man's a man for a' that."

"The rank is but the guinea's stamp,
The man's the gowd for a' that;
A prince can make a belted knight,
A marquis, duke, and a' that;
But an honest man's aboon his might,
Guid faith, he mauna fu' that."

But, heigho, the sight of that humble bed on which the great gardener had rested his weary limbs and his working brain, associated with what he has now become, led us at once, if not to worship rank and title, at least to feel grateful to the Sovereign Lady, who, in knighting the gardener conferred not only an honour upon him, but on every one of us the humblest in the blue-aproned fraternity; adding, too, another proof, if proof were necessary, that in this favoured land of ours real genius combined with true merit will ultimately meet with due acknowledgment; and that even the humblest in station may aspire, if such be the bent of their ambition, to be enrolled in the ranks of the aristocracy of title, as well as the aristocracy of intellect, or the nobler aristocracy still of true greatness, because associated and identified with practical goodness.

That bed, too, might well furnish practical lessons to many of the young gardeners of the day. Much has lately appeared in gardening serials respecting their interests, their education, the means to be adopted for securing ultimate success—much that, if prudently followed, could not fail to elevate, improve, and make better men as well as better gardeners—much, however, having a decided tendency to give them false notions of their

social position—much to puff up with consequence, as if already they had the right to choose what they would do, and more fitted to direct and to order than cheerfully and with alacrity to obey—much leading them to found baseless expectations of what head gardeners and other friends could, would, or should do for them, instead of depending on their own self-denial, their own self-culture, inflexible integrity, and unremitting, unswerving attention to duty. From all I have heard of Sir Joseph Paxton when at Woodhall and elsewhere, no doubt can remain that to such self-culture, self-denial, unwearied industry, and unremitting attention to carry out the directions and instructions of his superiors as a great principle of duty, he was indebted for securing the approval of those for whom he laboured, and ultimately became fitted to be chosen as the gardener, and, what is more important, as disproving all the fallacies about mere good luck—fitted to continue the gardener of the Palace of the Peak, and to render its gardening events in horticultural history; fitted to be the designer of the splendid Crystal Palace; fitted to be listened to with marked attention as a senator in the legislative halls of the nation; fitted, perhaps, most of all to sustain worthily the greatness achieved—greatness, I believe, even less seen in the social distinction obtained, as in the simple well-known fact, that he has never turned an averted eye from an old acquaintance however humble, nor shown any diminished regard for all that concerns the best interests of his old brethren of the spade and the hoe. Would humble men aspire to obtain and sustain, even a very comparative respectability in position, similar means must be used, a similar pathway must be trodden. All other dependencies will ultimately end in disappointment. R. FISKE.

COMMON PLANTS.

THE Dandelion-like plant, *Doronicum austriacum*, has flowered well with me this spring; but the situation where it flowers and thrives best is a rich alluvial loam. Some plants, nearly twenty years old, growing on the bank of a river flower well, and grow to a large size from the river to the top of a hill, 600 feet above the level of the sea. The plants in the gardens gradually grow less in size, seldom flower well, and rarely live more than two years; yet in sheltered corners some good plants may be found which flower well.

Those readers of THE JOURNAL OF HORTICULTURE AND COTTAGE GARDENER who find it difficult to grow *Saxifraga oppositifolia* will find it more easy to grow *Thymus serpyllum hirsutum*—a variety of our common wild Thyme, and like the *Saxifraga* "a bonny tufty kind o' plant wi' a wee purple kind o' flower." It is a plant that is easy to grow in the rockery and mixed border. This winter, in places where the *Saxifraga oppositifolia* has died away, the *Thymus* has survived, and kept its downy leaf very well. I have a plant, one of the healthiest I ever had, and it has had no care bestowed upon it; the situation in which it is grown is cold and bleak, yet it promises to flower abundantly. The flowers of this *Thymus* are not so large or as good a colour as *S. oppositifolia*, still it is a plant worthy of a place in the rockery and mixed border.

I am well pleased to learn that the Editors of THE JOURNAL OF HORTICULTURE AND COTTAGE GARDENER are writing a work on the wild flowers of Great Britain. Such a work written in a popular form has long been needed, and may be of use to the lovers of our English Flora. If not already contemplated, let me suggest the propriety of their writing an English index—from the want of an index of local names many of our country Floras have been thrown aside and forgotten. That the present work may have an extensive sale and stir up a desire to be better acquainted with our wild flowers is the sincere desire of—RUSTIC ROBIN.

THE ILLUSTRATED BOUQUET.—In the last Number of the "Illustrated Bouquet" there is a magnificent double plate of *Alocasia metallica*, the most beautiful of all the fine-leaved plants in cultivation. Another fine plate of two varieties of *Lilium speciosum*, or of those commonly called Japan Lilies and *Lilium lancifolium*, under which the whole family of Lilies is described in sections, and their proper treatment explained; to which is added the monograph of all the ornamental bulbous and tuberous-rooted plants, which we have already noticed. The reason which induces us to notice this part of the "Illustrated Bouquet" more particularly at this time, however, is the coloured double plate, which exhibits at one bird's eye view the whole of the

glass structures, walks, views, and furniture, so to speak, of the establishment of Messrs. E. G. Henderson & Son's, in which may now be seen the finest collection of spring-flowering bulbs in full bloom—a circumstance which, we believe, induced Her Majesty and suite to take several drives down the Wellington Road this time last year.

REPORT ON THE GARDEN PEAS,

GROWN AT CHISWICK DURING 1860.

By ROBERT HOGG, LL.D., F.R.H.S., *Secretary to the Fruit Committee.*

(Continued from page 63.)

37. Burbidge's Eclipse ... NOBLE, COOPER, & BOLTON.

SYN: *Stubbs' Dwarf*.

The plant is a dwarf but robust grower, from 18 inches to 2 feet high. The foliage is dark green, slightly blotched. The stem is always simple, and produces from ten to twelve pods, which are generally in pairs, rarely single. They contain from five to six Peas, which are of good size, and closely packed. The ripe seed is large, uneven, oval, and of a blue colour.

Sown February 19th; bloomed June 13th; slatted June 25th; and fit for use July 13th.

This is the dwarfest of all the blue Peas, and is an excellent bearer.

38. Flack's Imperial NOBLE, COOPER, & BOLTON.

SYN: *Flack's Victory*; *Flack's Victoria*.

This variety, introduced about ten or twelve years ago as an improvement on *Bedman's Imperial*, appears now to represent the varieties formerly known as *Blue Imperial*, and *Bedman's Imperial*, and deservedly so, for it is the only one of the name really worth growing when true, and it requires careful selection to keep it so, from its tendency to degenerate into *Blue Prussian*. The plant is of a robust habit of growth, with a stem which is always branching, and generally about 3 feet high, producing dark green blotched foliage. The pods are from twelve to eighteen on a plant, generally in pairs, but frequently single, and contain from six to eight very large Peas, which are of an ovate shape, about half an inch long and seven-twentieths broad. The ripe seed is large, irregularly oval, and dark blue.

Sown February 19th; bloomed June 13th; slatted June 26th; and fit for use July 11th.

39. Banksian Marrow... FRASER, RICHARDSON, & GOAD.

This is evidently a form of the *Scimitar*, but with a less curved pod, and partaking a good deal of the character of an *Imperial*. The plant grows to the same height as both of these, and the pods come into use also at the same time. Though a good sort it is not materially distinct, and does not possess any superior merit.

40. Blue Scimitar NOBLE, COOPER, & BOLTON.

SYN: *Blue Sabre*; *Scimitar*.

The plant is a strong, robust grower 2½ feet to 3 feet high, generally with a simple stem, but sometimes branching, and having dark green blotched foliage. The stem bears from twelve to eighteen pods, which are also of a dark green colour, and very much curved and flattened. They are produced generally in pairs, and contain on an average nine to ten Peas in each. The ripe seed is irregularly oval and dark blue.

Sown February 19th; bloomed June 16th; slatted June 28th; and ready for use July 16th.

This is an old variety, and now very much grown by farmers and market-gardeners as a field crop, for the supply of the markets of large towns, the fine large dark green pods always commanding a ready sale. It is very prolific, and is without doubt one of the best varieties for culture on a large scale; but it is one which is very liable to degenerate, and demands very careful attention to preserve a pure stock.

VI. WHITE KNIGHT'S PEAS.

Ripe seed white, compressed and wrinkled. Foliage most frequently dark green and much blotched; but occasionally light green, slightly or not at all blotched.

41. Fairbeard's Nonpareil... NOBLE, COOPER, & BOLTON.

The plant is of a free but not vigorous growth, resembling the

Early Frames both in habit and in foliage, the latter being light green and not blotched. The stems are branching, 3½ feet to 4 feet high, and producing twelve to fourteen very full and plump pods, which are generally in pairs, and contain six to eight very closely packed Peas. The ripe seed is small, white, and wrinkled.

Sown February 19th; bloomed June 14th; slatted June 25th; and fit for use July 6th.

This is an early and very productive Pea, and comes into use at the same time as the Early Frames and the Early Ringwood. The Peas, however, are small, and as a wrinkled variety it is now surpassed by *Advancer*, which is earlier, and produces larger pods and Peas.

(To be continued.)

BLIND BLOOMS OF KEENS' SEEDLING.

IN answer to "C. H. C.," I can tell him for his satisfaction that a few years ago I was precisely similarly circumstanced with regard to the blooming of my Keens'. I had administered powerful manures, and I felt sure I had overdone it. The plants showed remarkable vigour, and for their colour, and growth, were considered wonderful. I allowed them to remain, occasionally forking amongst them, and giving a liberal supply of water in June. The following year I had the pleasure of seeing the same vigour and colour, accompanied by large clusters of bloom, which formed and ripened into beautiful fruit. I would say to "C. H. C.," Do not despair; if all goes on well you will be amply repaid next year.—W. P. D.

EVERGREENS FOR BACK WALL OF A VINERY OR GREENHOUSE.

MANY inquiries have been sent you from time to time as to the most suitable plant for the back wall of a greenhouse or vinery: therefore, I imagine my case to be that of many others. At one time of the year the back wall of my greenhouse or vinery (it serves me for both purposes) is shaded entirely, and is therefore unsuited to the growth of ornamental climbers, such as *Passiflora Buonapartean* or *Mandevilla suaveolens*. Each of these plants I have tried in its turn, and each has been most reluctantly discarded, on account of their not maturing their growth, and a tendency to red spider, which I found it impossible to keep under while my Grapes were in bloom; and the syringe was consequently laid aside. For twelve months past I have grown a fine plant of *Heliotrope*, and it has succeeded tolerably well. I am afraid, however, of my old enemy, the red spider, during the ensuing summer, as I believe that the last season was favourable to my purpose, and I escaped in consequence.

I shall be obliged by your stating if, in your opinion, I should succeed better with *Magnolia fuscata*. My house, measuring 20 feet by 10 feet, faces to the south, is about a mile from the sea, and being on a chalky subsoil is consequently very hot in the summer season.—BRIGHTON.

[We do not think the *Magnolia* will do in your case. If the back wall has any light at all through the Vines, *Camellias* would do well and flower well all the winter, when the Vines were bare. If the shade, however, is dense in summer, and you merely want a green wall, then we would recommend a plant of either—or one of each—of the *Cissus antarctica*, and the *Cissus campensis*; either would soon cover the space; two would do it sooner. There is a conservatory at Gorbambury, the south roof is glass, a large hipped roof facing the north is plastered inside; and one of these plants as far as we recollect, covers the back wall with a mantle of green. When established, it may be cut pretty well as freely as ivy.]

THE FLORAL MAGAZINE for May contains plates of three annuals—*Celosia cristata*, or the crimson-feathered Cockcomb, the tricoloured branching *Larkspur*, and striped *Pæony*-flowered; and a plate of *Verbenas*, one of which—*Grand Eastern*, looks almost like its great namesake amongst a party of smaller steamers. It is a noble-looking flower, though deficient in brightness of colour.

THE LITTLE MARKET-GARDENER;

OR,

HOW TO CULTIVATE AN ACRE OF LAND WHEN PROFIT IS THE CHIEF AIM, AND SHOWING HOW A FAMILY MAY BE SUPPORTED AND SOMETHING PUT BY FOR A RAINY DAY.

(Continued from page 9.)

WHEN you have planted your early Potatoes, and done all that I have recommended in former papers, you will have very little to do upon your one acre of land until the Cauliflowers and Savoy plants are ready for planting out. You will find you have now five rods of land unplanted—two for early Cauliflowers, and two for Savoy, and one for

EARLY TURNIPS.

Towards the latter end of April will be quite time enough for sowing one rod of early Turnips. Do not sow them under hedges, bushes, or trees; do not put any manure under them unless the land is very poor, and if it is a very small sprinkling of guano may be put on and dug in; about 5 lbs. to the rod will be quite enough. Do not be careful about trampling upon the land after it is dug, for it cannot be trampled too hard, so that you have a little loose soil upon the top for the seeds to vegetate in. I sow mine in rows about 1 foot apart, and I do not care if the seeds are not covered at all. The best sort that I have grown for market is the *Snowball*.

CELERY PLANTS.

Mind and look well to the Celery plants. Do not let them remain too long in the pots or pans to be drawn up weakly. If you think they will want pricking out before the Radishes are ready to draw, give them plenty of air, and get them by degrees from under the glass. As soon as the Radishes are off the land dig it over, and put one ton of good rotten manure on in the same way as I advised for Onions. Mark the plot out into beds, and prick out the Celery plants about 6 inches from row to row, and about 4 inches from each other in the row.

EARLY CAULIFLOWERS.

As soon as your Cauliflower plants are ready to prick out mark out two rods of land; have one ton of good rotten stable manure dug into that space deep and well. Do not use pig manure, for if you do you will have grubs kill all your plants. Guano would be the best for them if your land is in pretty good heart—in fact, it would be best for the Cauliflowers if the land was poor, only the land will not be so good for the next crop. When it is well dug form it into beds 3 feet 10 inches wide, and the walks between them about 1 foot wide. Then, 5½ inches from each outside, plant your best plants 20 inches from plant to plant, and one row up the middle. They will then stand 20 inches apart every way. You may then prick out a double row of plants to draw for sale between each of the two rows that are to stand for flowering, thus—

 do not remain there too long; if

 they are not sold pull them up,
 and plant them somewhere else. Earth up those that are to remain as soon as you take the others away, and they will want little else doing to them until they are fit to cut for market.

SAVOYS.

There is no better way to grow Savoy for market than the way I have advised for Cauliflowers, only you must have your beds wider, so that the rows will be 21 inches from each other, and you must insert the plants that are to remain 2 feet from each other in the rows; they will then be nearly 2 feet apart every way.

MANGOLD WURTZEL.

Towards the latter end of April you should sow 2 ozs. or 3 ozs. of Mangold seed (the Yellow Globe I think the most useful) on any bit of spare land to raise some plants for planting out as soon as the Cabbages are off the land.

I have grown very good Mangolds in this way. If the land is clean, dig it over deeply and well; but if it is not very clean, fork it over, and get all the weeds clean out of it, and plant the Mangolds 17½ inches from row to row, and 20 inches from each other in the rows; and if it is a dry time, give them a good soaking of water as soon as planted, and keep them well stirred between until the tops cover the land.

MANURE.

The making of manure is one of the principal things belong-

ing to market-gardening: therefore, do not let anything lie about that will make manure. Let all cabbage, broccoli, and cauliflower leaves, carrot tops, rhubarb leaves, pea haulm, and bean stalks, turnip tops, and all sorts of green things that have no seed upon them be brought, and thrown into the pigsty; and all sorts of weeds, cabbage, broccoli, and cauliflower stalks, and hedge brushings be put together to be charred; and see that you take care of every tub of soapuds, drainage from the pigsty, contents of the slop-bucket, and everything in the shape of liquid manure, and you may give the Raspberries and Rhubarb a good soaking with such a mixture once a-week from the 1st of May to the 1st of August; and you may give the Strawberries a good soaking or two whilst they are in bloom, and you may pour it between the rows of Cauliflowers, Cabbages, Red Cabbages, and Savoy; Celery, too, is very fond of a good soaking with it now and then.

As soon as the summer is over make a large heap of poor soil, and pour such liquids on it, turning it over now and then, and you will find this soil of more benefit to the land than any manure you can buy.

CHARRING.

I do not think there is anything better to put upon land, be it whatever sort of land it may, than charred rubbish. If gentlemen did but know the worth of it, and if men could be found that knew how to char the rubbish, thousands would be employed, and no labour would pay better.

Like everything else, it is very easy to do when you know how; but I have never yet seen the man at work at it that did know how. That it can be done, and done well, is quite certain; for I never saw a heap of vegetable rubbish in my life that I could not char, and I have oftentimes thought that if I were to do nothing but go about to teach people the art of charring I should do more good for my country than thousands who have died for it.

I will show you my way as well as I can upon paper; but a person must see it done to know how to do it well, and he must also have much practice before he is sure of success; for if the refuse is charred too much, I do not consider it good for anything, and if it is not charred enough, it is very little better than if it had not been charred at all; but of the two it is much better under than over done.

Never try to char in a round heap, for in that shape the middle is sure to be charred too much before the outside is charred at all.

In the first place, build up four outside walls in the form of a range of cucumber-pits, not more than 3 feet wide and about 18 inches high, but as long as you have rubbish enough to make it 3 feet high. Let a good fire of coal be lighted whilst you are building up the walls; place a large shovelful of the coal so lighted in the bottom of your pit, about every 2 feet along the middle; then some of your best burning stuff, and mind that you never let it blaze, and to prevent this, if it is fast-burning stuff, sprinkle a little soil upon it now and then, and if it is very slow-burning stuff sprinkle a little of the coal upon it now and then; keep placing rubbish upon it until it is about 3 feet high, and when it is burned through to the top begin at the one end and turn it all over whilst it is still burning, placing all the outside that is not charred in the middle. If you do it cleverly a better heap of stuff was never put on a garden.—THOS. JONES.

(To be continued.)

ROSEWOOD.

WE are much obliged for the following correction:—

"In looking through the April part of your JOURNAL OF HORTICULTURE I observed a mistake which I think ought to be corrected.

"At page 86, in answer to a correspondent, you say that Rosewood 'is the wood of *Physocalymma floribunda*;' and on referring to Dr. Hogg's 'Vegetable Kingdom' I find a similar statement, taken, I presume, from Don's Dictionary. If, however, you refer to 'Kew Miscellany,' v., page 269, you will see that Mr. Benthams, upon the authority of Dr. Allemão, of Rio Janeiro, attributes the Rosewood of commerce to an undetermined species of the genus *Macharium*, and accounts for Don's mistake by saying that it arose from a mistranslation of the word *Rosenholz*, which I find on reference to a German dictionary means *red wood*, and alludes to the red or rose colour of the wood of *Physocalymma*, and not to its odour. Mr. Benthams further adds that the German *Rosenholz* is the same as the 'Tulip-wood' of English cabinetmakers.

"Errors like that of Don are so frequently repeated and difficult of correction when once made, that I trust you will excuse my calling your attention to the answer in question.—ALEX. SMITH, *Kew*."

PINE-APPLE CULTURE.

A FEW years ago in THE COTTAGE GARDENER you drew attention, in an interesting series of articles, to the Hamiltonian system of growing Pines. That system must have long ere this been well proved by the great Pine growers of the country. As I am now starting a new house with pits to be heated by hot water, I should be glad of your advice as to whether it is expedient to grow Pines wholly, or in part, on the plan which Mr. Hamilton adopted.

I would ask, therefore, How are Pines *now* grown at Trentham, Chatsworth, and other places, where once the Hamiltonian system was tried? If so, and you approve of it, how am I to proceed when I obtain suckers?

Tan is expensive with us, I should therefore like to discard the use of it. Will my two hot-water pipes (4 inches) with 3 inches of rubble covered with loose slates and then 20 inches of soil, do in a pit 5 feet wide for growing the Pines or for plunging the pots?—PINE APPLE.

[So far as known to us, no new experiments on Pine-Apple culture will interfere with the general and particular directions to which our correspondent refers. We are unable personally to state the plan generally adopted at Chatsworth and Trentham *now*, perhaps some correspondent will supply our deficiency until we have an opportunity of personal observation. When we saw these places a number of years ago only a very small portion were grown on the Hamiltonian system. At Trentham, so far as we recollect, we never saw such stiff, short, hard-leaved, bushy, dwarf plants, and producing for their size such fine first-rate fruit. These results we attributed to the plants being near the glass, receiving abundance of top and bottom heat, plenty of air, plenty of atmospheric moisture when necessary, and to being planted out in a bed of fine fresh soil, partly charred and mixed with charcoal before being used. We noticed little of the pure Hamiltonian system. The plants were turned out when good-sized rooted suckers. When the fruit was cut one or two suckers were allowed to remain on the stool, and encouraged to grow freely by water and heat, and when well grown the sucker with its roots was removed and potted and plunged, and as that got full of roots it was brought to replace the stools removed, fresh soil being placed all round it. Nothing could answer better than the plan of Mr. Fleming's when I saw it. I think he had a few on the Hamiltonian system—that is, the stools left with one, two, or more suckers, and the soil put round them, and the suckers yielding fruit in turn, and more suckers selected as the fruit were cut. A constant and regular supply of bottom heat is next to indispensable to success with this system. When we tried it a little we found that it had all the merits the enthusiastic projector claimed for it, the chief of which we consider to be the getting abundance of fruit at but little trouble in comparison of the pot-succession system. To obtain fruit in regular succession, and to have them thoroughly under command, I would advise all beginners to begin with the pot plan, and then if they like, to turn out strong plants in a bed of soil, so that they may be freely rooting in it before they begin to show fruit. We would turn out only when, as in your case, you can have bottom heat to a nicety. Whatever may be the reason, many of our best growers, though saying nothing against the Hamiltonian system, when they have to meet the regular wants of a family, are falling back more on the pot system entirely, or, at least, are turning out the plants after they have been grown in pots to a good size before they are turned out. A saving of room is thus effected, as the plants when young will not require half the space. When rough, fibry, half-charred loam is used, even young plants will move with fine balls; but, in general, it is safest to have them in pots, and if pots rather undersized for the suckers are used, we think they root quicker than when planted in a bed of warm soil.

Mr. Ruffet, of Brockett Hall, Mr. Dawson, of Panshanger, and Mr. Beale, of Woodhall, so far as we recollect, grow chiefly in pots; but we are sure that either of these men would turn out first-rate fruit from either planting out ultimately, or planting out at once.

As affording better means of moving, stirring the soil, and the plunging medium, we would advise all beginners to begin with pots, unless they are such experienced waterers that they could put a tiny Cape Heath a few inches high in an eight-inch pot and grow it into a fine specimen. Even when so grown it is an advantage to leave the suckers on the old stool as long as convenient. These will dispose of the three first questions until we have time to go more into the subject, and see more around us; as from the idea that the flavour of the fruit spoils the flavour of the wine, we have grown none of late years.

The best sorts to grow for size we consider to be the White Providence, the Sugarloaf, and Enville. For size and flavour and early fruiting we prefer the Ripley Queen for spring and summer and autumn, and the Black Jamaica for winter, and the Smooth Antigua for any time, and a few others for variety.

The suckers promised you in autumn, if strong, 15 inches long, potted in six pots in rough loam and a little leaf mould in September, plunged into a bottom heat of 90°, will make nice-rooted plants before the new year, or thereabouts. The forwardest of these placed into nine-inch pots in February grown on will be fit to go into twelve-inch or fourteen-inch pots in June, and if encouraged will come in early in the season of 1863, the smaller and weaker ones coming in in the summer and autumn. Everything depends on the size and the condition of the sucker. We have taken strong plant suckers from a stool in September, potted them with a ball, and started them into fruit in March or April. Unless the suckers you receive have come no great distance and are not extra large in size and with roots attached to them, what you receive in September or October, 1861, could hardly be expected to ripen fine fruit before the spring and summer of 1863.

For reasons given we would prefer potting such, and if tan is not to be had, there might be a foot or 15 inches of tree-leaves. Both are useful to the plants from the decomposition of carbon they throw into the atmosphere of the house. This is increased by sprinkling the plunging medium when dry with liquid manure without watering the plants if they do not require it.

The two pipes will give heat enough for bottom heat for a five-foot bed. Openings, such as drain-pipes, should be left, so that at times you can pour manure water down among your rubble, and thus nourish with rich vapour the lower roots of the plants, when it might be undesirable, as in cold, dull weather, to wet the soil much in which the plants are growing, whether in pots or planted. The rougher, more fibry, and open the material used for growing the plants, though closely pressed, the more freely may clear manure waterings be given in the growing and swelling seasons.—R. FISCH.

GROUND THERMOMETER.—We have had submitted for our inspection what appears to be an instrument of great usefulness to the gardener. It is a Ground Thermometer, invented and made by Mr. Casella, of Hatton Garden, who has already introduced several cheap and useful philosophical apparatuses for gardening purposes. The annexed figure furnishes a good representation of this instrument, which consists of a piece of stout ash wood hollowed out in the centre, into which a thermometer is introduced. From the upper part of this piece of wood a chaumfer is cut on which the graduated scale is fixed, and the lower end is shod with a tip of thick brass. The purposes to which this instrument is applicable are various. It serves the ordinary purposes of a thermometer; but its special use is to test the temperature of the soil by thrusting it as deep as possible into the earth; to ascertain the temperature of the bottom heat of dung, bark, or hot-water beds; and it is also used as a dibber for planting or pricking out of small plants. It appears to us to be a very handy instrument, and the price being 4s. 6d., it is within the reach of those who follow gardening either as a pleasure or a profession.

PHENOMENA OF THE SEASON.—What a severe frost we had here (Woodstock) last night (May 8th). I took care to be before the sun with my Asparagus this morning, by cutting every head and casting them into cold water to thaw, which it did

without detriment to them. My neighbours' Potatoes are all "laid flat;" so I gain a point there, as my own, on my system, do not appear above ground for a week to come. Seven shoots only of my Esperiones are injured by the frost. My Vines are breaking very well and promising; but I long to behold the finish of this "Black-thorn winter." The drones appeared in my apiary to-day, which is with me ten days earlier than usual.—UPWARDS AND ONWARDS.

THE ROYAL HORTICULTURAL SOCIETY'S GARDEN AT KENSINGTON GORE.

THE Society's new Garden at Kensington Gore is fast assuming form. The turfing is all but finished, and the last plantings are some noble-looking specimens of *Araucaria imbricata*, brought all the way from Exeter, with large balls tied and sewed up in strong mats. The large trees were banded up the trunks as high as to the branches with bands of hay or straw, and in dry weather they syringe the whole plant, bandage and all—an excellent plan—from early in April to the turn of the night after Midsummer.

The strike among the masons has hindered the completion of the canals and water-basins, but they are going on with them fast now. They put in concrete as for the foundation of a fortress, a foot deep, or nearly so, all over the bottom. It is then easy to build brickwork in cement over the sides of the large bed of concrete, and to finish sides and bottom in cement. That beats all clay puddling in cheapness, in duration, and in efficiency.

I only wish the Londoners, great and small, could see that also as the cheapest way to make garden walks. My way of making walks is merely concreting 3 inches deep with chalk instead of lime, and with lime where chalk is not; then before the 3 inches of concrete are set, and after being well rolled, just to cover the surface with the eighth of an inch of the finest-sifted gravel, to roll immediately, and in three days they are as hard as the bottom of their canals and just as durable. A garden walk 6 feet wide and one mile long could be weeded for twelve months under 1s. the mile. I made the calculation in the garden at Shrubland Park, where, if the gravel were reduced to the width of 6 feet there would be six miles of walks, and for some years the walks there cost only 5s. per annum to weed them.—D. BEATON.

CULTURE OF THE PEACH—No. 1.

SOIL.—I propose in this and a few following communications, to offer some remarks on Peach culture, and the probable cause of success or failure in the different localities in which it is grown; and, as the subject is one of great importance to the gardening world, I will on the present occasion confine myself more especially to one of the conditions on which I base its well or ill doing—namely, the soil in which it is planted; and at a future opportunity will enter into the other features connected with it, as a tree more indebted to the cultivator for his assistance than any other that is capable of withstanding our English winters.

As I have had several inquiries about the condition of the trees, and the crop of fruit the past season, I may so far depart from the intention I set out with of leaving that subject for another time, as to say that the crop was as abundant as in the generality of years, but the flavour was indifferent. In giving a description of the crops of wall fruit—which in the general acceptance of the term includes Peaches, Nectarines, and Apricots—it is common to refer to the general characteristics of the district for such fruits doing well or otherwise. Now, unfortunately, I cannot say the Peach and Nectarine are at home on the soils generally met with here (Linton); on the contrary, I have generally maintained that the Peach likes a soil and situation diametrically opposite to the one we often see it grown in. A Peach under very careful management may grow, and even seem to prosper in dry, chalky, or limestone soil; but its well-being is more due to the careful cultivation it receives, and the pains taken to guard it against the evils its situation entails upon it; but the time at length comes when some disease inherent in that soil will no longer be kept down, and, despite the able and energetic management of the cultivator, the tree perishes all at once, or is so much disfigured and injured by the attack it has received that it is no longer a useful tree. Generally some other agent than the soil it grows in receives the blame of this, and I do not by any means infer but that sometimes other causes will occasion the evils complained of: but I

certainly do think that an attack of insects, or of mildew, is rather the consequence of disease than the cause of it, and I regard the condition of the plant at the time it is attacked as of the most vital importance to know ere we decide on condemning the enemy that does not do the most harm. That soils have much to do with the welfare of all plants and fruits is well known, and that the Peach may be made to grow in a soil at variance with what it likes is also true; but it cannot be made to grow so well in that soil, and consequently, cannot be in a position to endure the evils it is beset with in a climate so different from its native one. Some plants whose natural habitats are dry walls or other dry situations may be made to grow in swamps; but they do not grow so well in the latter place, and the same may be said of the Peach: consequently, we may infer that the Peach, too, has its favourite material to grow in, and the question is, Where is its locality and by what means are we to know it?

In entering on this subject it is hardly necessary to travel out of Great Britain, only so far as is necessary to refer to its doing so well in the central and southern States of the North American Union. In like manner we are told it is at home in Australia, and, I believe, is scattered freely over the western and part of the centre of the great Asiatic Continent, and this region we are told is the native home of the Peach. But it is not necessary to trace it to its origin. Its cultivation in America may also be passed by; but as it is said to thrive so well in Australia, it is worth while taking a glance at the condition of the soil and other features there, to see in what way we may expect to copy it here. In some of those extensive tracts of land which consist of a thin black crust, rather than a fine mellow soil adapted to husbandry, the Peach is said to thrive and do well, even where many native trees and shrubs cease to do so: consequently, we must look for something either in the soil or climate, or both, to cause it to do so. The climate we cannot well imitate out of doors, and we still hope to hear of the Peach being successfully grown there: we must, therefore, endeavour to show how it is likely the soil we have may be made more congenial to it by as simple an addition to its component parts as well can be given; and as has been shown, the depth of soil is not always a criterion of its doing well at or near the antipodes, we must look to other conditions as well, and take a peep at the state of the water that drains from such a soil, and where we find it what is locally termed brackish and unfit to drink, a tolerable hint is thrown out what we may expect from a soil the chemical composition of which differs so widely from the one we are so much accustomed to plant the Peach tree in.

The readers of THE JOURNAL OF HORTICULTURE will, perhaps, remember, that about three years ago I called attention to the excellent state the Peach trees were in at Knowsley, the princely seat of the Earl of Derby; and as that place is only some six or seven miles from the west coast, and from where the westerly gales frequently drive the salt spray so detrimental to so many things, but which I believe to be beneficial to the Peach, we may from this conclude that salt is a necessary ingredient in the soil which produces the Peach; and as I have also seen the Peach thrive remarkably well near the east coast, in a soil apparently widely different from the one at Knowsley and Lathom House, which I have more particularly described, I cannot but think that the saline particles which pervade the atmosphere have exercised some influence on the soil, and that both united are suited to the wants of the Peach. It is true that excellent Peach trees may be met with at great distances from the coast—in fact, in the interior of the kingdom; but salt is also found at other places than the seashore, and may not the soil in the neighbourhood be more or less impregnated with this article so as to become suitable to the growth of the fruit we now call attention to? and as all soils are not alike constituted, it is reasonable to suppose that the one which contains a greater proportion of salt than is generally met with, is the one most suited to the growth of this useful and yet somewhat capricious tree.

In the twentieth volume of THE COTTAGE GARDENER, page 71, a correspondent informs us that in the plains surrounding Buenos Ayres the Peach thrives with extraordinary vigour, in a soil that seems almost encrusted with salt after the heavy rains have subsided; and at page 58 of the same volume another correspondent speaks of the value of this much despised article as tending to improve the Peach; and as, has been before alluded to, the vigorous condition it is met with in Australia where the water is so bad, we may conclude that the salt pervading the district has much to do with its fertility as well as spoiling the waters; and, having arrived at that conclusion, it is not difficult to reduce

this theory to practice, for the article we have to deal with enters more easily into the composition of most things than almost any kind of manurial substance we know of; and we hope to hear of its being more extensively used as a renovator to trees falling into decay, or in preserving those that are healthy from going wrong.

In making the above comments on the Peach, I am well aware I am offering an opinion at variance with that of some eminent Peach growers. Our late talented writer on these matters, Mr. Errington, was of a different opinion, and thought the well-being of the Peach trees along the western coast line was owing to the greater amount of moisture the air is loaded with there than more eastward; and some writers attribute early or late frosts as the source of all their misfortunes with the Peach. Certain

it is that these circumstances have something to do in the matter, nevertheless I feel inclined to think the radical evil lies in the absence of that agent I have been advising the use of. And though many other untoward circumstances may be urged, and much useful knowledge obtained by the parties advocating different theories, or it may be practical results, coming forward and stating them in *THE JOURNAL OF HORTICULTURE*; and if I am wrong I will frankly admit it; if otherwise, I trust those who have the means of giving this useful ingredient a fair trial on such soils as they are forced to plant their Peach trees in, will come forward and state the result; and at another time I will endeavour to explain what may be done to make soils which at present are antagonistic to the well-being of the Peach better adapted to its growth.

J. ROBSON.

CONVOLVULUS MAURITANICUS.

THIS pretty little half-shrubby *Convolvulus* is a native of the interior of northern Africa, where it was discovered by M. Séjourné, and first described by M. Boissier in his "*Plantes d'Espagne*."

ovate, or roundish-ovate, an inch and a half long. The flowers are an inch to an inch and a quarter across, with a purplish-blue limb, and a white centre and tube. They are produced one to three together on long slender footstalks from the axils of every leaf; and these, coupled with the trailing habit of the plant, give it a graceful and ornamental appearance when grown in suspended pots or baskets.

During winter *Convolvulus mauritanicus* requires the protection of a pit or greenhouse. In spring, if cut back, it throws out a profusion of its long trailing shoots, and as the season advances it may be turned out as a bedding plant, or introduced into vases or on rockwork, where it keeps up a succession of bloom all through the season.

For growing in pots or suspended baskets and vases it is admirably adapted, its fine slender trailing habit being so applicable to that style of decoration.

Our figure was taken from a plant grown in the nursery of Messrs. E. G. Henderson & Son, of Wellington Road, St. John's Wood, from whose Catalogue we extract the following:—

"A highly ornamental and drooping half-shrubby plant, of a neat, well-branched, and slender habit, with roundish-oblong leaves, and a profusion of very elegant light blue blossoms upwards of an inch in width, forming an admirable plant for suspended basket or vases; also an unique and effective bedding plant, or carpet-like belt, for surrounding flower-beds, and a charming object for rockwork and flower-garden baskets. Its gracefully procumbent growth is seen to great advantage when planted on the top of small mounds, by which its picturesque porcelain-blue blossoms are conspicuously beautiful. The plants require protection in a greenhouse or pit, and in the early spring season it should be cut back, and as its dense growth breaks at every joint, it blooms profusely from the corresponding shoots at each axil and side branch: by thus obtaining a free and luxuriant growth, it will prove a charming plant for almost every desirable position in flower gardens and conservatories where favourably exposed to light. Its free and long-continued bloom will prove its value in adding to the desirable variety of plants for the purposes above named."

The plant is of a trailing habit of growth, with long filiform flexuose stems, which are not branched, and entirely covered in every part with very minute soft white hairs. The leaves are

and conservatories where favourably exposed to light. Its free and long-continued bloom will prove its value in adding to the desirable variety of plants for the purposes above named."

THE TWO GREAT PEAKS OF THE BUNDERPOOCH AND
VALLEY OF THE JUMNA.

THE HIMALAYAS AND THEIR PRODUCTIONS.

No imagination, however fertile, can realise the snowy range of the Himalayas, and no pen can pourtray adequately the grand massings of rocks, and forests, and snow-clothed pinacles towering through the clouds, spread over hundreds of miles in this chain of the loftiest mountains of our world. The best description we have met with is by one who unites in his own person the rarely-combined qualifications of the sportsman and the author, and he thus tells of his first look from Landour, upon these marvellous elevations.

"It was, indeed, well worthy of the burst of admiration which broke from my lips as, before sunrise next morning, we rounded the shoulder of the hill and stood on the north side of the Landour ridge, and I saw for the first time, rising before me in all its majestic sublimity, the long unbroken line of snowy mountains. To have as extensive a view as possible, we ascended to the top of a little hill from which both the snowy range and the plains were visible. No words can do justice to what was now before us. One-half the horizon was bounded by an unbroken wall of snow, surmounted by fantastic peaks of every conceivable form, rising clear and high above the vast wave-like wooded ranges that stretched before us to its base. Directly in our front it appeared to be about forty miles off; the outline clearly and sharply defined against the sky, and the smooth rock, in places too perpendicular for the snow to lie, plainly visible. Receding into distance on either hand it was more indistinct, particularly to the west, where a dim shadowy vapour blended snow and sky together. From some of the highest peaks light clouds seemed to rise, drifting slowly away in the direction of the wind, but disappearing soon after leaving the peak from which they rose. This is a common phenomenon, and I then imagined it was a vapour drawn from the snow by the action of the atmosphere, but I afterwards found its origin to be this: The snow in some places becomes frozen into particles as fine as dust, and is then whirled into the air by the first gust of wind, at a distance appearing like a light cloud. I had pictured to myself ranges rising one above another till the last was topped with snow, but the intervening ranges seemed nearly all of the same height as the one on which we stood, while, enthroned in its own lonely grandeur, the snowy one rose majestically as if from the summit of the most distant. The scene may not have the awfully grand appearance that some present, when one has penetrated into the recesses of the snowy mountains themselves, and standing at their feet gazes on the vast spectre-like masses rising directly overhead; but there is something so striking in its calm and still repose when seen from this distance, that the first view of the snowy range from the Landour ridge will impress many minds with more lasting feelings of admiration than closer views. As the sun rose the whole lost much of its vivid clearness, a shroud-like vapour gradually stealing over the scene, so that in many places the before sharp outline of the snowy peaks against the sky, could no longer be traced. Turning our faces the other way, the valley of the Dhoon lay at our feet, encircled by the low range of wooded hills, the dark aspect of which was broken here and there by bright yellow spots, the sites of landslips, which sparkled like beds of gold in the sunlight. The valley appeared nearly all in a state of nature, either dense forest or grass jungle—the reclaimed portion round the town of Deyrah, on each side of the road from Rajpore, and here and there round isolated villages, looked small indeed in comparison with the whole. The rich green tint of the spring crops of corn in the cultivated parts was at this distance very striking, and contrasted well with the brown sombre hue of the grass jungle, and the dark shades of the forest. Beyond the hills that enclosed the valley the plains of India stretched far out into the distance, the horizon so remote that the division of earth and

sky could nowhere be distinctly made out. Two silver threads meandering through the maze showed the courses of the Ganges and Jumna, and small silver specks the lakes and swamps. Who could gaze on such a scene, the ideal of sublimity on one hand and of calm and repose on the other, and not exclaim, 'What a glorious creation!'—(*A Summer Ramble in the Himalayas.*)

Those who have visited Mont Blanc may deceive themselves into the belief that they can form a mental estimate of the Himalayas, but such a comparison is vain, that comparative pigmy reaches little higher than to the girdle of those giants of Hindostan. It rises to an elevation of 15,732 feet, whilst they exceed 28,000 feet!

We are almost successfully tempted to wander far and wide, as well as high, among those glorious mountains, but those regions of the range characterised by the Conifers and the Rhododendrons are our more fitting theme. These, too, will be the most interesting to our readers, and to aid them in comprehending these regions we give the following extract and maps from a communication to the late Baron Von Humboldt from Dr. J. D. Hooker.

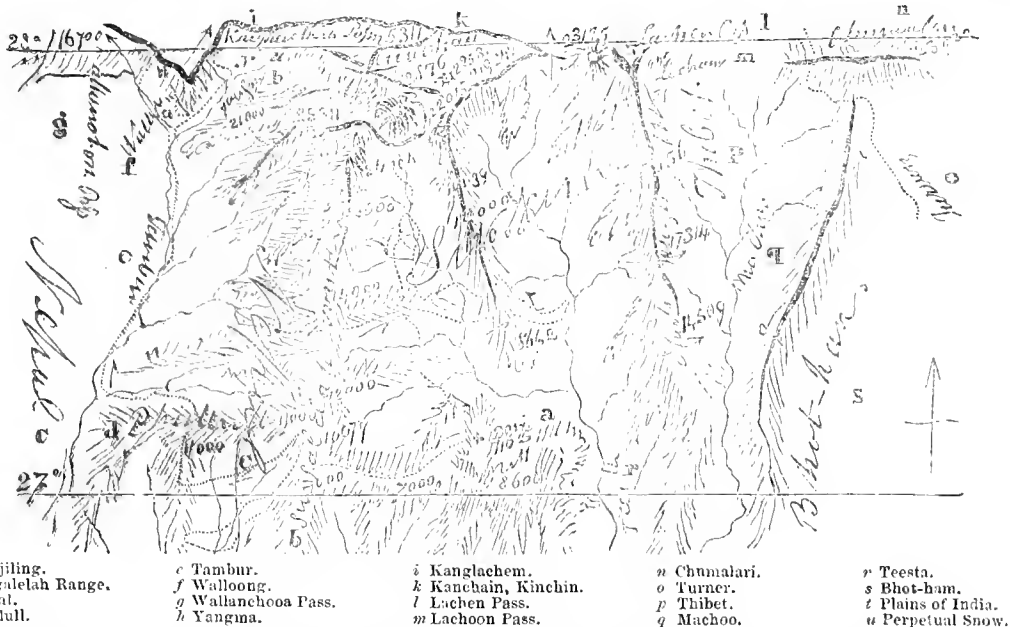

Dr. Hooker started from Darjeeling at the foot of the range, and thus proceeds with his narrative:—

"I packed up my things and set out on my road, which ran westward, through deep defiles (3000 feet above the sea) and leading up a very high cross chain running out from Singalelah, ascends to a height of 11,000 feet. Thus I made my way to the Tambar river, in the valley of which runs the eastern highway leading from Ham (or Nam?) to Walloong, on the Thibetian border. Reaching this river, at an elevation of only 2500 feet above the sea, I ascended it, making my way as well as I could through a tropical vegetation, which reaches to constantly snow-covered spurs of the Kauchain. On the 25th of November I arrived at the boundary of Rice-cultivation and Hindooism, and the commencement of a temperate zone, and of the Bhotia people. The change from buffalo and rice, to beef and wheat

"The village of Walloong lies about 11,000 feet above the sea. The pass, situated a day and a half's march on the further side, is about twelve miles W.N.W. from the Kauchain peaks, and twenty-five from the latter. We reached the summit in two days, with much toil, for the ground at 12,000 feet was deeply covered with October snow, which at 13,000 feet does not melt until the following March. The summit of the pass is 16,700 feet high, but still three days' march distant from the plain of Thibet, which is here cut off by two mighty chains, branches of the Kauchain, which, of less elevation than my point of view, stretch in a northward direction toward the plain. Mountains and valleys were now covered deeply with snow.

"The limit of the eternal snow, at this point, is, as nearly as I could determine, 14,500 feet above the sea; and, judging from what I saw afterwards, I believe this is near the truth, although it is impossible to speak with exactness—by the bounding of the snow which had fallen in October.

"This is not the most eastern of the passes leading to Thibet, and, therefore, not the nearest point to Kauchain attainable in eastern Nepal. I resolved to visit, on my return to Walloong, the valley lying eastward of this, where a higher but seldomer-used pass led to Thibet. Descending the Tambar, I penetrated, in a north-east direction, into the Yangua valley, which expands into a broad, treeless ravine, wholly filled up with lake-beds. These beds are bounded by enormous rocky dams, which have been hurled across the valley when it was all under water. To express it briefly, while the Thibet Plain has accumulated its drift-deposits (1000 feet thick, by actual measurement, in western Thibet) the waters, which stood at a height of 15,000 feet in the Yangua valley, have left parallel roads or banks, on the flanks of this valley, which are as fine as those of Glen Roy, in Scotland. Lateral ravines have washed out masses of rock into the valley, which have been piled up into mountains, and perfectly bridged it over, so that, on the subsidence of the waters, they formed dams. The terraces are perfectly parallel on the two sides of the

The broad black line indicates perpetual snow.

was sudden. Ascending still higher, through stupendous mountain defiles, toward Walloong, the second transition from beef to bison (the Yak, the progenitor of which, is the undescribed wild bison of the Thibetian plains) was more gradual.

"Walloong is the Cis-Himalayan commercial depôt of the Bhotias. Here I was received with mistrust, and obstacles of all kinds were opposed to my design of going towards the passes, which were the more effective that the season was far advanced, and they withheld provisions from me. Luckily I had still a dozen Bhotan men with me, a parcel of scamps who would frighten any one, and who, by insulting, abusing the authorities, and threatening to break open the warehouses, placed me in a condition to start for the passes after a halt of two days.

valley, above the lake-beds; they ascend like steps, along the steep declivities, and are everywhere strewn with vast blocks of rock. In the side valleys, one sees now only small patches of glacier ice, which have deposited drift and debris, just in the same manner as the vast beds twenty yards long, have been deposited by the greater ice.

"I have here sketched a plan of the valley, and shown, that these bridges across the valley, a mile long, one 800 feet high, and all composed of masses of rock, heaped up too irregularly to allow of a vegetation extending to them, are a real effect of mountain ice, which has been flooded out from the side valleys."

"These astonishing records of the power of glacier ice admit of no other explanation; and many particulars so vividly remind

me of the shores of the Antarctic Ocean, that I cannot have any doubt of the correctness of my conclusions.

"The village of Yangma, at the fork of the terraced valley, lies above the limit of shrubby plants, and stands on the flanks of a level terrace of drift and rocks, rising 300 feet above the bottom of the valley, and two miles long. The village is 13,700 feet above the sea (according to the reading of two barometers, and the determination of the boiling-point) at which height Wheat, Peas, and Radishes were cultivated, the harvest falling in the month of September.

"From hence I turned in the north-western direction, toward the Kanglach Pass, which leads to Thibet; but, on account of the deep snow, had great difficulty to attain the height of 16,000 feet. Three dry lake-beds in this valley (eight in all), were of exactly the same origin as those below the village. The uppermost, at 16,000 feet was quite filled with snow, and surrounded by glacier mountains."

We must postpone our extracts relative to the plants of the Himalaya until a future Number.

EFFECTS OF LAST WINTER ON PLANTS IN ENGLAND.

(Continued from page 99.)

THE following notice of the present state of the Coniferae and shrubs here, will serve to show the devastation which has taken place. The situation of the grounds is exposed. The soil is of an adhesive, argillaceous nature.

Arancaria imbricata.—Very much cut; the primary shoots are all killed back.

Cedrus deodara.—Very much injured; and in many instances they have lost the whole of their leaves, and the young wood of last year killed.

Cupressus funebris, killed; *C. Goveniana*, killed; *C. Knightiana*, browned; *C. macrocarpa*, killed; *C. McNabiana*, killed; *C. sempervirens*, all but; *C. torulosa*, killed; *C. Udeana*, killed.

Fitzroya patagonica.—Killed.

Pinus apulcensis, killed; *P. Benthamiana*, browned; *P. Gerardiana*, killed; *P. insignis*, killed; *P. Llaveana*, killed; *P. macrocarpa*, much injured; *P. montezeuma*, much browned; *P. Sabiniiana*, killed.

Sequoia sempervirens.—Very much browned.

Libocedrus chilensis.—Killed.

Thuja gigantea and *Wellingtonia* are perfectly green.

Arbutus unedo and *procera* are all killed.

Aucuba japonica.—Much injured, but breaking back.

Coanothus papillosus.—Killed.

Cerasus lauro-cerasus (Common Laurel).—All killed down to the old wood, and have lost the whole of their leaves.

Cerasus lusitana (Portugal Laurel).—Is in some instances but slightly injured, whereas in others it has lost most of its leaves.

Cistus ladaniferus.—All killed.

Cotoneaster microphylla.—Killed down to the ground.

Escallonia macrantha.—Killed to the ground.

Eunonymus japonicus and *variegata*.—Killed.

Fabiana imbricata.—On a south wall, killed down.

Forsythia viridissima.—Slightly injured.

Garrya elliptica.—Killed partly down.

Ilex.—Several of the varieties have suffered, and in some instances are losing their leaves.

Laurus nobilis (Bay).—Killed down to the ground.

Ligustrum japonicum.—Killed.

Magnolia grandiflora.—Grown against a south wall very much cut.

Phillyrea rhamnus, *P. angustifolia*, and *P. latifolia*.—Very much injured, several being quite killed.

Photinia serrulata.—Killed.

Quercus ilex.—Several of the varieties are slightly injured, the young twigs being killed back.

Rhamnus alaternus are quite killed.

Ulex europæus flore-pleno and *stricta*.—Killed.

Yucca.—Some of the varieties are injured.

Tritoma uvaria.—Quite killed.

Gynærium argenteum are all killed.

Jasminum Reevesii.—Killed down to the ground.

Roses have suffered severely. Budded Roses, and Roses on all stocks are mostly killed. Climbers upon walls where not protected are all cut, but are springing from the root. Gloire de Dijon is the only Rose in its class that has defied the weather.

I may mention that Hybrid Perpetuals upon their own roots are now springing very strongly, and I expect a good autumn bloom from them.

I would suggest the advisableness of planting many more of the Roses upon their own roots than is usually done. I well recollect Mr. Beaton years ago suggesting the advantage of planting Hybrid Perpetual Roses on their own roots, and I hope he will give us his present opinion on that subject, being convinced that such will be duly appreciated.—GEORGE WESTLAND, Kingston Hall, Notts.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THIN out all advancing crops as soon as they are fit; if not attended to in good time the plants are drawn up weakly, and never produce a satisfactory crop. *Broccoli*, prick out the plants, as also *Cabbages*, as soon as they are fit to handle; to be watered after transplanting, and shaded from the mid-day sun for a time. When thus treated the plants are always better than when left to grow in the seed-bed till wanted for final planting. *Celery*, attend to in its various stages; do not let it suffer for want of water; if the surface of the soil gets hard and caked, stir it up. *Cucumbers*, the ridge lately recommended will now be in a fit state to receive the plants. Plant them out without delay, and shade the hand-lights for a few days. *Dwarf Kidney Beans*, plant out those that were sown in pots or boxes on a warm border. Sow a succession crop, as also *Scarlet Runners*, and *Haricot Beans* where they are esteemed. *Leeks*, make a sowing, to plant out for winter use. *Lettuce*, prick out a few about once a-week. *Potatoes*, earth up those that have just made their appearance above ground. *Tomatoes*, plant out in light soil under a south wall; also *Chilies*, *Capsicums*, and *Basil*. Sow seeds of *Vegetable Marrow*, and *Cucumbers* for succession and for Gherkins.

FLOWER GARDEN.

As all apprehensions of danger from sharp frosts may now be considered over, the planting out of half-hardy plants for the summer and autumn decoration of the flower garden may now be proceeded with, and carried on as vigorously as circumstances will permit. If previous instructions have been followed the plants will now be so injured to the weather that even a few slight frosts, if they should occur, will do them no harm. When planting the beds the principal object should be to produce a striking effect by employing plants only of a decided colour, principally red, blue, and yellow, using white for separating the different divisions. The system is very effective where the colours are well contrasted, particularly when viewed from a distance, and where the beds are not numerous, and where there is some breadth of grass or gravel to neutralise. Where more variety is considered pleasing, there is no want of colour to effect any desired object. This is accomplished by using a decided colour in the centre of the bed, and surrounding it with an edging of a contrast colour. See that all edgings hitherto neglected are put in order for the summer; do not edge beyond the original boundary, and keep the walks filled with gravel. Let the roller be passed frequently along the edges in order to

level them to the walk; this takes away the harshness of the outline. Auriculas should now be placed on a north border, the seed will ripen very well there if the pots are well drained and placed on a layer of ashes to prevent the ingress of worms, they will take no harm from exposure. Polyanthus require more shading than the Auricula, else they are very liable to the attacks of red spider. Do not delay putting down the sticks to the Carnations and Picotees, tie up Pinks, and plant out Dahlias that have been properly hardened off.

FRUIT GARDEN.

Water all trees that have been planted this season, and give them an extra mulching of dung. See that neither the red spider nor green fly get ahead on wall trees, nor the caterpillar on Gooseberry bushes. Where Gooseberries are much esteemed for dessert, thin the fruit on some of the choicest sorts, to be watered occasionally with liquid manure and to be protected with nets from birds.

STOVE.

As the plants increase in size allow them plenty of room, especially plants with large foliage. It will be necessary to use the syringe frequently to keep down insects, assisted by fumigation where thrips are likely to get established. The white and brown scale can be kept under by carefully hand-washing the infested plants with a strong lather of brown soap and water, soft brushes, or pieces of sponge, are the best instruments to be used for the purpose that no injury may be done to the leaves. Aclimenes to be placed where more air can be given, to be staked out neatly as the shoots advance. Gloxinias require a partially shaded situation and moist heat; and Gesneras similar treatment with the addition of more light.

GREENHOUSE AND CONSERVATORY.

A good number of plants—such as Epacris, Diosmas, and many other New Holland plants, Myrtles and other things that have done flowering may be removed to any other convenient place, and being cut back and repotted, will, if properly attended to, make fine plants by the autumn. Make a sowing of Chinese Primrose and Cinerarias for spring decoration. W. KEANE.

DOINGS OF THE LAST WEEK.

CONTINUED turning all available ground in the kitchen and flower garden. We are still keeping the latter as much as possible rough and in ridges, to expose a greater surface to the atmosphere. Independently of these turnings the ground is yet very cold, and offers no hope of us being able to turn out bedding plants for a fortnight or three weeks to come. Watered early Peas with heated weak soot water with a little lime in it, alike to supply moisture and heat, and keep the grubs at a distance. Never saw so many as this season; but thanks to liming, catching and trapping, they are now comparatively harmless. A few brewer's grains laid in little heaps, or a broccoli leaf rubbed with fat on the lower side, are rare things for attracting the slimy fraternity, and once luxuriating in fat, or getting drunk on the grains, they may be quickly picked up with the help of a lantern the last thing at night. Watered the Cabbage and Cauliflower plants a second time with warmed manure water, as the first had given them such a start as fairly to dispose of more bolting for the season; pulled the earth with a hoe to the stems, alike to keep moisture and the heat from the water in, technically earthed them up, but left a hollow along the row to hold more water if necessary, instead of drawing up the ridge to a point to throw off water as nicely as a span-rooted house, or a well-feathered duck's wing. Sowed more Peas in succession. Spawned the Mushroom-bed when surface about 80°—the bed mentioned the other week as consisting chiefly of stubble and tree leaves. Put 2 inches of droppings all over, and a thin layer of sheep-droppings picked off the feeding-ground; and as the heat is mild, will earth up to-morrow. Of course, I should have preferred nice droppings from a stable filled with horses fed for riding and hunting; but if a man now-a-days cannot get what he wishes, he must learn to be content with getting what he can. Fine Mushroom-beds are made from well-fermented dung, sweet as for a hotbed; but that, too, just now, is out of my reach, with the dung of four horses to supply all my multitudinous wants.

Kept thinning Grapes at all convenient opportunities, night and morning and dull days, it being next to manslaughter to keep a poor hard-working fellow at such work with the sun beating upon him and almost making his brains to melt. The

people who insist on such work being done at such times are rightly served when the berries are discoloured or rusted, and all sorts of ways, through sweaty hands, greasy hair, and scissors that under such circumstances will not be kept clean. Such a practice, like nailing on a north wall with the ground covered with snow and the frost not much above zero, we hope to see numbered with the things that were, so that the rising generation may escape the aches and pains and general debility that now too often overtake the gardener when he ought to be just in his prime.

"Good gardening consists in attention to trifles," was a favourite dictum of one of our old masters. We never pass a season without finding it too true. A favourite rule of our own is, if, from economy, air cannot be left in forcing-houses and pits all night, give a little early in the morning at the highest point in the house or pit, even if from the cold becoming more intense it should require to be taken away ere long. The theory of the thing is, that the enclosed air of the night is changed, and if the sun should come out strong, the smallest opening—say half an inch or less in a nine-foot house, will prevent the heat and vapour so accumulating as to scald the plants. We had three lights in a pit of as pretty Melon plants as the eye ever rested on, trained to wire at a suitable distance from the glass, and air being forgotten too long on a sunny morning many leaves were scalded, and many are a little spotted as if you had poured boiling water in squirts; and now, though they will get over it, instead of being first in, as they would undoubtedly have been, they will be beat by a succession crop in a dung-frame. Our active assistant would not believe that any harm was done, because the leaves showed little signs for two or three days; but the first notch of air given told us clearly what would be the case. The evil under such circumstances might have been lessened, if instead of giving air at all the place had been closely shaded, and the walls, &c., inside moistened, and air only given when the house had got much cooled. When houses are thus left too long without air, and in cold, sunny weather in spring, the plants run a double risk—first of being parboiled by hot vapour, and then burned by a rush of dry, cold air when they are thus weakened. If a small opening at every sash had been given an hour before, even a quarter of an inch, the heated vapour would have so escaped, and the plants been so dry in consequence, that if the sun with the air on had raised the temperature to 90° or 100° there would have been no harm done.

I said so much last week on the training of the Melon to prevent much pruning, that I said little or nothing about the setting and perfecting of the fruit. I am not sure now what I exactly did say, and, therefore, if there is a line of repetition I hope to be forgiven. As soon as the tertiary shoots push from the axils of the leaves at the ends of the secondary shoots from which the buds have not been removed, and show fruit at its first or second joint, they must be stopped either at the fruit or the joint above it. I prefer the latter. If they do not show fruit at the first or second joint, stop, that they may throw out fresh shoots. If, however, there are six or seven of these side or tertiary shoots at the point of each of these main secondary shoots or bines, they will generally show enough of fruit without this stopping again. The great thing is to get the right number on each shoot or plant to show and set at once. This when we desired to have four fruit on each plant, and found we were likely to have only one, if that was a large-fruited kind, whenever that one began to swell it would so take all the running that others would have no chance. It is best, therefore, to pull or cut off that one, so that a fresh start may be made by getting all the requisite number of flowers in bloom at a time. This secured, the setting is almost a matter of certainty, owing to the strength in the plant before the blooms are allowed to show at all. Two things more, however, are essential. First, there must be enough moisture at the roots to secure a healthy vegetation, and yet the surface of the bed must be dry to secure a dry atmosphere, to secure a free setting. Experienced hands, therefore, try to give as much water before the blossom opens as will keep the plants healthy until the young fruit are swelling, *giving no water whilst the plants are in bloom*. If there is any difficulty in this, it is a good plan to have two small drain-tiles—say 3 inches or 4 inches in diameter, and 1 foot long, set up in the soil of each light, the top end covered with a lid. Through these water may be poured to keep up moisture below, even when the surface of the bed is dry. If the surface of the bed is thus dry, the blossoms may be fertilised in the usual manner, and they will generally soon begin to swell. It requires a good

portion of water to swell a Melon nicely; but care should be taken not to give much in dull weather, and none at all as the fruit approaches perfection, or it is likely to be deficient in flavour, and also liable to crack and rot. If the soil should be too dry to meet the demands of the plant and fruit, it should be watered below by such means as the above, whilst the surface soil is comparatively dry.

Moved out Strawberries when gathered from; and some hardly worth house room from what remained on them, were placed in a warm place to afford some pickings of small ones. Placed in a number of those potted the other week. Prince of Wales and others swelling nicely, and Queens setting freely in the sunny weather. Never had the plants so small in autumn, and yet there has been nothing to complain about as to the crops. Like a correspondent's case the other week, I begin to believe it is possible to have these in pots too strong. I can well believe his case, as an amateur invited me to look at his garden, and chiefly his large Strawberry-bed the other day, which he said looked so green and nice—and so it was if the leaves were the useful part, like the Cabbages, for there was scarcely a single truss of bloom. I would not have risked a threepenny-piece on all the Strawberries, though there ought to have been some bushels. From what I learned, I believe high feeding and the severe frost combined did the mischief.

Greenhouse and bedding plants much the same as the last week or two.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

MENDING INDIANRUBBER HOSE (*Kate*).—To stop the holes in the hose, dissolve Indianrubber in naphtha until this becomes as thick as cream, and then, when the hose is quite dry, insert the cement between the lips of the wounds and press them together. Do not use the hose until the cement has dried. The buds between the sashes ought not to be rubbed off, nor do we see any impossibility in the way of moving the Vine stems a few inches inwards from the front of the orchard-house, so as to allow the windows to be opened quite enough for ventilation, although they do turn on pivots. However, on such difficulties, they are the best judges who can see them with their own eyes.

APPRENTICESHIP TO NURSERYMEN (*H. G. S.*).—The premiums required vary so much that we should mislead you by quoting any. Advise, stating what you require for your son, and judge for yourself from the answers you receive. The cheapest are not always the most preferable. There is no work published exclusively on hybridising.

DRAINING-TOOLS (*A Subscriber*).—Write to two or three of the implement makers who advertise in our columns. Tell them what you require, and ask them to send you prices.

BELT BEFORE A HOUSE (*Franciscea*).—Your bill has been read three times after being carefully considered upstairs by a select committee, who altered that clause only which defines the belt of trees as "a monument of your own and your husband's love of horticulture," to that of your love for one another. The old Yew-hedge 15 feet high, bare at bottom and flourishing above, is not to be removed till the second week in September. Meanwhile, however, a trench 2 feet wide and as deep as the roots, is to be cut on each side of the hedge, and at 3 feet from the stems, and all the roots are to be cut to within that distance. The best of the soil, and some fresh soil or road drift to be added, is to be returned into the trenches for young roots to form there; and all the old boughs of the Yews, and the young ones that are longer than 2 feet from the stems, are to be cut to that distance along the bottom of the hedge, and those at the top to 18 inches, regulating the cuts so as to make a regular slope all the way to the top. Roots, tops, cuts, and digging out and filling in to be done and finished in proper garden-like style as soon as hands can do them this present May. After that the whole space for the belt is to be trench 2 feet deep, mixing the top and bottom soil as much as possible, and carting some fresh soil from somewhere—no matter how heavy or how light it happens to be, so there be a dozen loads of it to spread over the trenched surface, and to have the sun and rains of summer to mellow it, and render the top part the best for planting with in September. In that month the hedge is to be transplanted, and set at 3 feet from the boundary wall, and nearly as close together as the plants stand now, or as near to that as the roots will allow of in planting. Each tree is to be watered most abundantly as it is being filled in, in order to wash the soil into every opening between the roots, and between the bottom of the balls and the subsoil. The reason why Scotch Firs do not look well in your neighbourhood is the bad way they have therabouts of not sufficiently preparing the soil for them. But under the treatment we have directed for the Yews they will be as sure as Scotch all over the borders; and more sure if you choose the trees now, and see they are not much higher than the boundary wall, or 6 feet. A row of them, or they one-half and *Pinus maritima* the other half, alternately, must come in front of the Yew-hedge; and 6 feet from it, and in front of them, variegated Hollies, Portugal Laurels, and some flowering shrubs—as Lilac, Guelder Rose, two or three Honeysuckles tied to stakes, Ribes sanguineum, with what you please in smaller things in front, only have plenty of evergreen *Berberis aquifolium*. We will send the Index when you favour us with your direction.

FLOWER-GARDEN PLAN (*A New Reader*).—Your plan and the planting do you much credit. But there is one mistake in the midst of it. The large mixed circle completely spoils the effect of one of the best plans we have seen this season. Get up some moonlight night, turf that entirely over, and say nothing about it.

WALTONIAN CASE (*An Old Subscriber*).—We are not sure how much water is needed for the circulation in the Waltonian Case, and Mr. West is now out of our rounds to see him. But we recollect the quantity is very small indeed in proportion to the size, and that is the whole secret of the success of the contrivance. Three pints and a half is one-half more water than we should think necessary with a lamp burning and keeping the water constantly up to near the boiling-point. If both ends of your Case are not heated there must be something wrong inside the Case—perhaps a bit of rag or cork has got into some of the channels. The inside of a Waltonian Case is nearly as intricate as the inside of a Geneva watch, and no one could make the least approach to making one from all the drawings which have been made of it. No one but the maker can put to rights any derangement in the working part of the Waltonian Case. All that we know is that Mr. West made every one of the tin cases in which the heating circulation is made from the first, and that the stock in hand has not yet been equal to the demand for it. In the winter of 1859 and 1860 some of the men were up most nights, and yet in February and March every post brought complaints of delays in supplying the article—that is a fact that is known to a score of the people of Surbiton. All last May and June they were incessant in their endeavours to prepare a full stock for this spring's propagation, and your Case could not only not belong to the first edition as you surmise, but it could not even be of the sixth edition.—D. BEATON.

MANURE FOR A FLOWER GARDEN (*A Subscriber*).—For use by "a lady," where no labour can be had for using stable manure, and where there is no tank for liquid manure—by which we presume you mean house sewage—there are no fertilisers better than guano and superphosphate of lime, which can be had at our office in tin canisters, with directions how to employ them.

FLOWER-BEDS (*A Cheshire Subscriber*).—If the windows or front view of this garden is opposite 4 or 3 the planting is very good, but if the front view is opposite 2 or 5 there is the objection of the cold colours being in front instead of being the farthest from the eye. Some indication of the house or of the front view should accompany every garden plan.

FLOWER-GARDEN PLANS (*R. F. S.*).—You have done this very difficult garden remarkably well this season. The *Humeas* will give it an air of graceful elegance planted in that style, and we should think any one looking over it from beyond the moat must be struck with the whole arrangement. (*A. M. T.*).—The planting is good, but the principle of composition planting is destroyed in the centre bed. The plants in that centre bed ought to be in the end *Verbena*-beds, and the white *Verbenas* in the centre, with *Purple King Verbena* round them, which would give a better contrast than the crimson, but the crimson will do.

PEAR TREE UNFRUITFUL—EVERGREEN HEDGE FOR TERRACE (*H.*).—The bloom and spray which you have sent tell why your Pear-tree blossoms never set, though they appear in profusion. The blossom only partially developed, and the spray covered with lichen, proclaim weakness in the tree, arising from poverty in the soil. Remove at once carefully all the top soil down to the first roots from within a circle of six-feet radius from the tree's stem. Replace that soil with some fresh rich loam, and during the drought of summer mulch over the roots and water abundantly. Brush over the stem and main branches with a creamy liquid made of fresh-slaked lime, soot, and water. We would never plant a Holly-hedge as an accompaniment to a terrace of any pretensions, but we should employ Yew or Box—and whichever we used, to be kept as close as the best Brussels carpet in doors. If there is much light stonework about the terrace, Yew is the best to go with it; if not, Box is as cheap and as good as Yew, and you can plant either with four-feet-high plants and any other height up to 10 feet or 12 feet, according to the price you will incur. The distance between the plants—be they Holly, Yew, Box, or Privet—will be according to the sizes of the plants entirely, from 9 inches to 4 feet apart. All hedges ought to consist of only one row, and that row in the middle of the bed prepared for the plants. That bed is the grand secret of all good hedges. Any one can plant, and a child can water, but without a thorough good bed of deeply stirred or trenched soil, no hedge worth a place on a terrace can be raised. The time to plant a Yew-hedge of large plants is early in September; if the plants are under 5 feet, the last of August and the first day of September are equally good, and the twentieth to the twenty-fifth day the best to plant good-sized Holly. But if the ground was quite ready, and the plants near, the first week in June is about as good a season to plant well-rooted Hollies under 6 feet as any in the whole year. The plan's should have 3 feet clear from the turf. Hollies look best if they are carefully cut with a knife instead of shearing them. From your inquiries we would strongly advise you to give up all ideas of a Holly-hedge and take Yew instead.

LEAVES OF SCARLET GERANIUMS SPOTTED (*Salopia*).—We have never before seen this disease of yellow minute spots in *Scarlet Geraniums*. It looks as if from the attacks of some scaly insect. But after planting out the plants will grow out of it; then by taking healthy cuttings and letting the old plants die out, the disease will be easily got rid of.

VERBENAS FOR BEDDING—CINERARIA SOWING (*Inquirer*).—The "best" *Verbena* of any colour depends entirely on the way it is to be used. The best white for you is Mrs. Holford, the best scarlet for your purpose is Robinson's Defiance, and the best purple *Verbena* for every one is *Purple King Cinerarias* for early spring flowering should be sown this week, again in June, and towards the end of July.

STOPPING DIELYTRAS (*Idem*).—These must not be stopped to make the plants dwarf and bushy. What could be the use of having such a common border plant otherwise than as it is? Most people cannot get it strong enough for the only purpose it is intended for—for fine blooming. Cramping it, or keeping it down by any means, makes it only less graceful, less flowering. But if you like to dwarf it, stop it by all means, and at every other joint all through the season. You can even disbud it and make it more compact that way: but we warn every one not to do so who prefers the graceful to the dumpty.

CONCRETE WALKS (*A. P. S.*).—First foundation of stones and brickbats 6 inches deep; then a layer of chalk or lime mixed with stones (one chalk to ten of stones) 3 inches deep, with a rise of 2 inches in the centre: therefore in the centre the layer will be 5 inches deep.

CUTTING IVY (*A. Subcriber, Ireland*).—We prefer doing this in March or April, because then the green shoots soon cover over all the knife or scissor marks. If done earlier, the Ivy presents a dead appearance until the young twigs come, and if not done in autumn or winter a sharp frost is apt to injure it, otherwise Ivy may be cut at any time. But keeping looks in view, we prefer from the middle to the end of April.

VINES FRUITFUL AT POINTS OF SHOOTS (*Idem*).—You must not think of cutting back the shoots which have no blossom to one eye now—that would make matters much worse. If the spur system is to be continued, that must be done in the autumn or winter pruning. But meanwhile these shoots should be allowed to grow until they are 18 inches long, and then be stopped, and kept stopped as they grow in summer; and if thick all laterals may be picked out of them, except two or three at the joints near their junction with the older stem. That will help to give them strength and more organised matter for next season. If these side shoots are trained crosswise from a rafter to rafter instead of up the rafter, they will receive more light and be rendered more fruitful, but then they will give more shade to the plants below. You cannot have it both ways. If the Vines are very strong and not fruitful the roots might be raised, or a young shoot near the base left to grow without stopping for 7 feet or 8 feet. As it grows the side shoots should be shortened to a bud or two, not to check the Vine; but as the young shoot gains strength, remove them altogether as far as the young shoot extends. This young shoot could have all the laterals left, but stopped at the first joint, and stopped at another joint as they grow afterwards, until the wood begins to ripen, when they should be gradually removed. The following year this young shoot would mount to the top of the house, and the lower end would bear. The following year the old stem might be removed.

NECTARING LEAVES CURLING (*Vegetarian*).—Such leaves are apt to be produced on gross or older shoots, and the remedy is to stop such shoots early, so that the strength may be directed into two or more shoots instead of one shoot. Such appearances are also produced in cold wet seasons, the sap collecting in undue amount, owing to the deficiency of heat to carry off the redundant water by perspiration. This often ends in the leaves blistering. Such leaves are best removed, as sound healthy ones often come in their place. When, as in your case, the malady seems constitutional, we should conclude the cause to be the roots growing in a soil too deep, too moist, and too rich. If the trees were lifted carefully, or at least the greater portion of the roots raised in October, and placed within 9 inches of the surface in poor light soil, and mulched with litter to keep the heat in the ground, we believe your trees would be healthy next season.

CATERPILLAR OF GOOSEBERRY SAW-FLY (*H. C. K.*).—Dust them, by means of a dredging-box, with fish powder or white hellebore.

LIQUID MANURES (*Ignoramus*).—For flowers, one bucket of the urine from your cow-house to six or seven buckets of water would be none too weak. Salt may be sprinkled in a solid state over Asparagus-beds once a month, during its period of growth, from April to October. One pound to a square rod would be enough applied thus frequently. Bone manure in powder, may be put in the drills with the seed or round the roots. This powder will not dissolve in water, but superphosphate of lime prepared from bones will. The latter may be used about one ounce to each bucket of water. When you have finished cutting Sea-kale leave the plants entirely uncovered.

GREENHOUSE FOR BEDDING PLANTS (*Thorne*).—The site, aspect south, though shaded after noon, will do well enough for the purpose. Of course you mean to exclude the frost.

CUCUMBERS DISEASED (*H. C. W.*).—The bits of leaves were so dried that we can scarcely make out what is the matter with them, but conclude it to be the spot, and we are sorry to say it; for, once set in, the only remedy we know of is burning the whole, clearing out the whole soil, washing all the frames with sulphur and lime, and beginning afresh. The following will palliate the evil, and may ultimately produce a cure, as it has done with us once or twice, but the trouble is great and the result not certain. Wash the frames or walls with sulphur and lime, remove as much of the surface soil as the roots will permit of, cut off the worst leaves and stems, give extra heat in the way of linings—not to make the bottom heat too high, but to raise the atmospheric temperature as noted in "Doings of the Week," so as to permit of free ventilation during the day and a little at night. Fresh healthy growth may thus be expected; and every bit showing signs of disease must be removed. Sour saturated soil will bring it on in Cucumbers. It happens rarer with Melons, a stagnant atmosphere delights the disease.

GRAPES (*W. E. Butler*).—There is a great difference between the White Sweetwater and the Royal Muscadine. In the former the bunch is very loose, and contains a great many small, undeveloped, and abortive berries among an equal proportion of round, thin, semi-transparent-skinned ones, and the bunch is short, and oblong. In the Royal Muscadine the bunches are long and tapering, and the berries are all equally and well developed. There is a variety of opinions about the Esperione Grape, and we are not in a position to say much about it. It is not impossible that it may prove to be the Frankenthal, which, though sometimes called by the same name, is quite distinct from the Black Hamburgh. The sort you are growing for Esperione seems from your description to be Black Prince. Your Black Hamburghs will not be too heavily cropped with seventeen bunches on them. Let there be only one bunch on a lateral, and thin the bunches well. You will find that when we have made the purchase of the index compulsory, we have always charged 4d. for the Number in which it was issued, but as there is an immense increase in the number of the subscribers to the new form of THE COTTAGE GARDENER, we did not think it fair that they should have to pay for a title of which they did not possess the volume. We shall be pleased to have your experience of orchard-house culture.

ADVICE (*Ignoramus*).—We always have had, and always shall have, information for all classes of gardeners; and when we say *all*, the answer is given to you who require us to be exclusively for one class. Any information you may specially need will be most readily given.

GLADIOLI SEEDLINGS—BULB-POTS (*P. H. Watts, Woodstock, Canada West*).—Plant them out in the border as soon as the spring with you is quite confirmed. Harden them off by degrees for the removal. Take up the bulbs as soon as the foliage has died down in autumn. You may forward them a little under glass in spring preparatory to planting out, though in England we should not do so. Perhaps keeping them in pots of earth, merely excluding frost, would be the better plan even in Canada, turning the whole ball out into the border when spring arrives. Draining-pipes 4 inches diameter will do very well as a rough substitute for bulb-pots. Your other questions are answered in another page.

BEGONIA REX IN BORDERS—**PURPLE ORACH** (*G. B.*).—*Begonia Rex*, an all the strong-growing variegated *Begonias*, will grow as freely as Tom Thumb Geranium out in the open air in most of the sheltered gardens south of London, and very likely all over the kingdom; but none of them must be plunged in pots. Turn them out of the pots with the ball entire, but previously well moistened. The same treatment must be adopted with *Farfugium grande*, which may be planted out as early as the Dahlias, but the *Begonias* not till the weather is settled and is warm in June, and then, the older and stronger the plants are the better they will succeed. The Purple Orach grows from 3 feet to 4 feet high in good rich soil, but does best trained down, and to be constantly stopped and kept from flowering.

SMALL FERN CASE (*E. C.*).—We should have *Cystopteris fragilis* only, with *Hymenophyllum tunbridgense* round it; and we should have the *Hymenophyllum* round the *Adiantum capillus-Veneris* which you have in the other shade. The taller Ferns require the more dwarf to cover the soil beneath them.

VEGETABLE SOIL FOR PEACH TREES (*A Subscriber*).—This, formed of weed and other refuse, will do very well to mix with your poor, sandy soil for a Peach-border; but you should add some loam or clay, and keep the surface mulched. See what Mr. Robson says to-day about the soil for Peach trees.

KIDDEAN SYSTEM OF HEATING.—W. A. will oblige us by fuller details of his mode, and if with illustrative plan or plans the better. We have a letter for him if he will send us his address.

NAME OF PLANT (*T. F.*).—Your plant is *Pedicularis sylvatica*.

FLOWER SHOWS FOR 1861.

- MAY 18th. CRYSTAL PALACE. (Plants, Cut Flowers, and Fruit.) *Sec.*, W. Houghton.
JUNE 5th and 6th. ROYAL HORTICULTURAL SOCIETY. (Plants and Fruit.) *Garden Superintendent*, G. Eyles.
JUNE 12th and 13th. YORK. *Sec.*, J. Wilson.
JUNE 19th and 20th. BRIGHTON AND SUSSEX FLORICULTURAL AND HORTICULTURAL SOCIETY. *Sec.*, E. Carpenter.
JUNE 25th. ROMFORD. (Plants, Flowers, and Fruit.) *Sec.*, Mr. George Griggs, Romford.
JULY 6th. CRYSTAL PALACE. (Rose Show.) *Sec.*, W. Houghton.
JULY 10th. ROYAL HORTICULTURAL SOCIETY. (Rose Show.) *Garden Superintendent*, G. Eyles.
SEPTEMBER 4th and 5th. CRYSTAL PALACE. (Dahlias, Cut Flowers of other descriptions, and Fruit.) *Sec.*, W. Houghton.
SEPTEMBER 11th. ROYAL HORTICULTURAL SOCIETY. (Dahlias and other Cut Flowers.) *Garden Superintendent*, G. Eyles.
SEPTEMBER 18th and 19th. BRIGHTON AND SUSSEX. *Sec.*, E. CARPENTER.
NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums.) *Garden Superintendent*, G. Eyles.
NOVEMBER 12th and 13th. STONE NEWINGTON CHRYSANTHEMUM SOCIETY. *Sec.*, W. T. Howe.
NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show.) *Sec.*, W. Houghton.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

- MAY 21st, 22nd, and 23rd. CHESTERFIELD AND SCARSDALE. *Hon. Sec.*, Mr. Thos. P. Wood, jun., Boythorpe House, near Chesterfield. Entries close May 1st.
MAY 22nd and 23rd. BEVERLEY. *Hon. Sec.*, H. Adams. Entries close May 4th.
JUNE 4th, 5th, and 6th. BATH AND WEST OF ENGLAND. *Steward*, S. Pittman, Esq. Entries close May 4th.
JUNE 19th. THORNTON. *Sec.*, Mr. Joseph Richardson. Entries close June 12th.
JUNE 19th, 20th, and 21st. COALBROOKDALE. *Secs.*, J. B. Chune, and Henry Boycroft, Coalbrookdale.
JUNE 25th. ESSEX. *Sec.*, W. R. Emson, Slough House, Halkstead, Essex.
JUNE 29th. DRIFFIELD. *Sec.*, Mr. R. Davison. Entries close June 22nd.
JUNE 29th and 30th. TAUNTON. *Sec.*, Mr. Charles Bailance. Entries close June 14th.
JULY 3rd, 4th, and 5th. BLACKPOOL AND WEST LANCASHIRE. *Sec.*, Mr. E. Fowler, jun., Market Street, Blackpool. Entries close June 30th.
AUGUST 26th, 27th, 28th, and 29th. CRYSTAL PALACE SUMMER SNOW. *Sec.*, W. Houghton.
SEPTEMBER 3rd. POCCINGTON (Yorkshire). *Sec.*, Mr. Thomas Grant. Entries close August 26th.
SEPTEMBER 24th. BUNGINGHAM. *Sec.*, R. Taylor, Bridgnorth.
DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. *Sec.*, Mr. J. B. Lythall, 14, Temple Street. Entries close November 1st.
DECEMBER 11th, 12th, 13th, and 14th. CRYSTAL PALACE WINTER SNOW. *Sec.*, W. Houghton.

LET FOWLS RISE WHEN THEY PLEASE.

It is not necessary that the great expenses indulged in by some poultry amateurs should be incurred. With poultry, as with animals of a higher order, the things necessary are not much.

Except to find their eggs, if they are wanderers, fowls do not now want as much looking after as they do in the winter. They may be allowed to roost about where they will—in shrubs or trees, or cart-houses, under sheds, and on the rafters of empty barns: they will be the better for it. The nights get shorter and warmer, the earth brings forth food, and they are early risers. It is almost literally with them that "the early bird picks up the worm." There is much food on the grass in the cool of the morning when it is damp with dew, which disappears as the sun gets up. For this reason those who keep their fowls fastened

into their houses at night have much to answer for, because it is essential they should be at liberty the first thing in the morning. "Well," says one, "so they are; gardener lets them out every morning before six." Granted, but in June and July they want to be prowling at half-past three. Nature is a good manager. Fowls following her dictates exert themselves during the freshness of the morning; the heat of the mid-day is for a long siesta.

Except a well-to-do pig that grunts out its satisfaction at having a bellyful and nothing to do, we know no animal that shows more enjoyment than a healthy fowl during the middle hours of a summer's day. It chooses a dry bank, well and thoroughly exposed to the sun, and the dustier the better. If it be a hen, she looks for a small hollow; she lies on her side and sets to work increasing and deepening the hole; when she has partly buried herself she opens her feathers, she covers herself with dust, and then composes herself, lulled by the heat. It would be useless for her to prowl about, the earth is dry and parched; but when the evening approaches she will be out again. Fowls have this desire to dust and bask in common with Game. Pheasants and Partridges do it, and in the middle of the day there is little hope of finding any of them except in sunny places. They feed at daybreak and in the evening.

We have been led to this, because it can no longer be necessary to keep fowls closely shut up, and because it is not only economical that they should find the greater part of their food, but it is also very beneficial to them to do so. It is with them as with ourselves—the hotter the weather the less we are inclined to eat, and the more we long for something of a refreshing nature. They find their fruits and salads in wandering about. The hen may be allowed her liberty with her chickens by day in warm and dry weather, but it is better she should be shut up at night, because, otherwise, she is very apt to drag her chickens about in the cold morning dew, among high grass and weeds, where they perish. While roaming during the day, it is with chickens as with adults—they not only find part of their own food, but that part which is best for them.

HEN BROODY WITHOUT LAYING.

I HAVE a small Bantam hen that about a month ago showed a desire to sit. She had four Dorking eggs given her, and is now the proud mother of two chickens (having turned the other eggs out of the nest). The only remarkable thing is, that the hen has not laid since 1859. She is about four years old.—J. H. T.

[We are always very glad to hear of such things as that you recount. We had some years ago an old East Indian hen which would sit all the year round—in fact, whenever eggs were put under her. She laid seldom, but she did lay sometimes. Are you sure the Bantam has not laid and eaten her eggs? We have been surprised to see the short time in which a hen will devour that she has just laid, and also the cleanly operation she makes of it. We have watched, and ran to the nest, to find no trace of one.]

CANARY BREEDING.

LAST year I purchased a hen rather late in the season, placing her with a cock in a roomy breeding-cage. Almost immediately she built her nest, afterwards sitting almost continuously. Much to my surprise no eggs were laid. After a week or ten days I placed several Bullfinch's eggs under her. She sat them the due time (without laying). Unfortunately they proved addled, though it was not her fault. After this I destroyed the nest and prevented her making another. This year she has built her nest quite a fortnight ago, sitting very irregularly, but no eggs are produced.—A VEXED ONE.

[Take away the hen Canary's nest, wait a week or so and then let her build again, when, perhaps, she will lay; if not, you may give her some eggs of any of the Finches to rear, after which she will build again and lay, unless she is really barren. Barren hens are, however, often useful as nurses, as they may frequently be induced to sit at any time, which is sometimes a great convenience.—B. P. B.]

THE DOTRELL.—We saw the first of this eccentric summer bird on the last day of April. Epicures will hail their arrival. We shall be glad of any information respecting these most interesting birds.

THE CANARY AND THE BRITISH FINCHES.

(Continued from page 71.)

10.—THE BRAMBLEFINCH (*Fringilla Montifringilla*.)

German, Bergfink or Tannenfink,
French, Pinçon d'Ardenne, or Pinçon Royal.

THE Bramblefinch, known also by the names of Brambling, Mountainfinch, Beechfinch, and Firfinch, is a winter visitor to this country. Like the Siskin, it is very irregular in its visits.

In size and shape they much resemble the Chaffinch, but are slightly stouter, and stand rather higher on the legs.

In plumage they are very handsome birds. The beak is pointed and yellowish in colour, with a brown tip; in summer it changes to a bluish shade. The irides are brown, and the feet flesh-coloured.

In the male the head is a bright black, with bluish and purple reflections; the sides of the breast, lesser wing-coverts, and under wing-feathers, orange buff; the feathers of the back have broad, russet brown edges; the quill-feathers of the wings and tail are black; the primary wing-feathers have a little, and the secondaries much white at the base, which form a white mark on the wings, and give the bird a very dappled appearance when it flies. The larger wing-coverts are black, with orange tips; the rump and under tail-coverts, white. In autumn after the moult, the plumage is much duller on account of the feathers, particularly of the head being edged or bordered with brown; but, during the winter, these ends are worn off, and by the spring the bird assumes his handsomest, or summer dress. The female is much duller in plumage; the feathers of the head and back are fringed with wide edges of brown, which give a much quieter tone to her whole plumage, and by which she is easily distinguished.

They breed in the north of Europe, and I have not heard of their nest having been found in this country. Bechstein says, "They make their nests on the thick firs and pines, of the moss that grows on those trees, and line it with hair; the hen lays five yellowish-spotted eggs, and the young ones are reared on insects." Their food consists of insects like that of the Chaffinches, and of the seeds of firs and pines, and they are very partial to beechnut; they also frequent the stubbles and eat other seeds. Mr. Seales, an agriculturist of Beecham, in the county of Norfolk, considers them of great service to his land, as they devoured in great abundance the seeds of the knot grass (*Polygonum aviculare*).

Although very handsome birds and easily tamed, their song is but poor, and they are considered quarrelsome in an aviary with other birds, but I have kept them in a room with many other birds without any such inconvenience. Their food may consist of canary seed, oats, millet, and occasionally a few insects, as mealworms, earwigs, &c.

Bechstein remarks, that if they have much hempseed they frequently become blind, and the head swells and causes death; he also states that they are easily trained to fly out and in at the window, and if allowed to roam in the room, will eat anything that comes to table.

Their call, *yack, yack, quark*, is very loud; and I have found them very restless at night in the migratory season, when they would often start from their perch, uttering a suppressed scream, and beat their heads against the top of the cage, causing a panic among the birds in the neighbouring cages.

On the Continent, pied, and even white specimens, have occasionally been met with.

I have endeavoured to breed from them with the Canary, but without success. Bechstein however, informs us that the hen Bramblefinch and cock Chaffinch produce very handsome Mules.—B. P. BRENT.

(To be continued.)

DECREASE OF STARLINGS AND OTHER BIRDS.—In the northern part of Hampshire, I have noticed a great falling off in these birds. I have a field of about four acres in front of my house which is a great resort for them, and notorious for the large flocks that frequent it. We have all noticed their disappearance since the frost. Blackbirds, Thrushes, and Bullfinches, are also scarce in the garden. I believe Sparrows are like flies, the more you kill the more you have. Will some of your readers tell us when first they heard the Nightingale and Cuckoo?—H. R.

TREATMENT OF PARROTS AND COCKATOOS.

HAVING kept and attentively observed the habits of Parrots and Cockatoos for many years, I cannot forbear noticing and lamenting the privations that unhappy family of birds must endure at the hands of "W. T." and his friends. No doubt they can exist on "sopped bread and hempseed;" so, too, can "W. T." on boiled mutton and bread; but both would be infinitely benefited by a change of diet. "W. T." would find his boiled mutton very wearisome after a month's experience.

Amongst my feathered pets is Coco (a grey Parrot) which was given me from the nest in Africa, looking at the time very like an exaggerated powder-puff. I have had him now many years, and his beauty and intelligence are remarkable. I ascribe his perfect health and brilliant plumage to the great variety of food allowed him; of course, the staple is sopped bread, but we give him fruit of all sorts—nuts and walnuts, of which he is particularly fond, well-picked bones, vegetables—in fact I deny him nothing but salt and fat; water every day, which he calls for when thirsty under the name of "milk," and never ceases reiterating, "Miss Ellen, milk, poor Coco, Miss Ellen milk," till attended to.

I think if "W. T." could see Coco's delight in bathing he would give his own bird a similar treat immediately. Coco goes through the most absurd antics of joy, dances round and round the basin (of tepid water) dips his head in, opens his mouth, and dabbles his tongue in the water, puts his head down quite close to the water, telling it in a confidential tone some of the eighty-seven sentences he has acquired, and finally goes through a prodigious splashing.

While on the subject of Parrots, I may mention a remedy given me by a dealer in them, for plucking out their feathers: it is to sprinkle the birds gently (so as not to frighten them) with a weak solution of alum in water; it soothes the irritation of skin which causes the habit, and also renders the taste of the feathers unpleasant to the bird.—E. V.

BEE-HIVES AND THEIR APPURTENANCES.

(Continued from page 109.)

HIVE-BOARDS.—Nine are of yellow pine, $1\frac{1}{2}$ inch thick, of the form seen in sketch (figs. 10 and 11), the square formed

Fig. 10.

Fig. 11.

16 inches, the round 18 inches in diameter. The unusual form of landing-board I devised for two reasons, to save the many tired foragers who might otherwise miss a narrow board and fall a prey to the lurking toad, and also to assist in keeping the thick thatch snug. It is always better to be well bevelled from the entrance to the front, to run off the moisture, and many a life may be saved on a wet, mild day, or a dewy morning, by its being stripped down in addition, into little channels with a fine gouge. The bees getting on their backs are by this means enabled to right themselves. The exact dimensions of the landing-board are $8\frac{1}{4}$ inches in length at the centre from the square, $10\frac{1}{2}$ inches point to point, $1\frac{1}{8}$ inch of a sweep at centre from a straight line between the points, and at the centre 6 inches wide. A portion 10 inches by $5\frac{1}{2}$ inches is cut out, if done neatly with a very fine saw, it may serve afterwards to work as a solid drawer, if not another bit is easily made to fit. A little brass knob is behind to draw it out by. A half-inch board 16 inches

square nailed on below across the grain of wood, serves the double purpose of preventing warping and a bottom to rest the feeding-trough upon. The outer edge of this half-inch board to be bevelled off for appearance's sake. This will be found a useful

means of supplying food as already mentioned. The narrow thin strip of wood at the top of the drawer as seen in the sketch, is to prevent dead bees or any refuse falling in when using the drawer, and so hinder its shutting close. On the bottom is nailed four pieces 1 inch square, mitred at the corners, leaving a central square of 9 inches as a frame to fit on a similar-sized piece nailed on the top of the pedestal. A pair of two-inch iron buttons or bars on the back part of the frame and one in front, serve to keep it in its place on the pedestal. The hive can be readily weighed without risk as often as the bee-keeper has a mind, by turning back the buttons, running in the sliding door, whenever the inmates are housed; and by means of the little iron hooks at the corners of the board, the hive is elevated as seen in sketch (fig. 5), the weight noted, the hive replaced, and the entrance opened without the bees ever being aware that there has "Been a chiel amang them taking notes."

SHADES.—To ward off the prejudicial effects of the winter's sun during a fall of snow or otherwise, on the thickness of the front of the landing-board drive a little bolt with a circular eye, a stout wire bent at one end to fix into it, and after running straight out for a foot or so, turned up perpendicularly. On this a square of wood rounded at the top with two little eye bolts behind works

up and down and about, so to throw the front of the hive into the shade. Small holes in this upright will admit a sprig to fit in any position, of course to be removed in spring.

PEDESTALS.—The authorities all rightly agree that these should be single, but only specify two materials, wood and iron, for their construction. The first, though the best oak charred and tarred, decays near the surface, and its downcome is only a question of time, the tragical consequences of which any apiarian can anticipate. The iron is liable to rust, and must be kept painted, and is, above all, too expensive for general use. I, therefore, devised for my own apiary a pedestal free from all these disadvantages. What I employ for the purpose are, *glazed fireclay faucet pipes*: they are strong, most durable, not affected by damp, being always glitteringly clean, require no paint, and, of course, do not rust, are too smooth for a mouse's foot, and, to crown all, so economical as to justify their universal adoption, the three-inch size costing 8d., and the four-inch 9d., in single pipes. They make such capital pedestals as entitle them to a place in the "Bee-keeper's Manual," or "honourable mention" by any apiarian society. I adapt them as follows:—Suppose we take the four-inch size, dress a circular bung 4 inches in diameter by 1 foot long (less length might do), of thoroughly seasoned wood: before fitting it tightly into the upper end of the pipe give it a good coating with white lead, dress the top smoothly with a hand-plane, prepare a board $5\frac{1}{2}$ inches broad, having a thickness of three-eighths of an inch behind, dressed to a sharp edge in front, cut out a circle $5\frac{1}{2}$ inches in diameter, and nail on the

Fig. 5.

top of the bung, this gives the bevel for the hive-board. On the top of this fix with extra stout nails a nine-inch square of wood inch-dressed, on which the floor-board is attached with buttons as already mentioned. When nailing it is safer to place a piece of wood up through the post to the ground to prevent its displacement. The three-inch size has a lighter appearance and is 30 inches long. The four-inch I think preferable, being 38 inches long, and the faucet end on this size sunk into the ground helps to steady the pipe (see fig. 5). A hole is to be opened to receive it, the earth put in gradually and well firmed as you proceed fixes it immovably, leaving 20 inches or so above the surface.

WATER TROUGHS are useful particularly in spring. Mine are of hewn stone 16 inches by 7½ inches outside, by 2 inches deep, leaving a rim 1 inch sunk into the earth, 1 inch above the surface. I used to place pebbles in the water, but observing bees greedily drinking at a ditch one day, not directly from the water, but through the medium of the moss upon the stones, took the hint and filled my troughs with nice specimens. By filling the trough every morning with water the moss grows and has a pretty appearance. Should blackbirds abound it is better preserved by a bit of net. A ready cheap substitute are the little oval troughs of fireclay used for fowls' drink, they are 16 inches by 7 inches, and cost 1s.—**A RENFREWSHIRE BEE-KEEPER.**

(To be continued.)

WINTERING BEES IN CANADA WEST.

"APRIL 10th bees went abroad for the first time and returned with pollen. 11th found hepaticas in bloom in the woods. This is my beginning, or rather second attempt. The first was on January 15th. I went for a hive, there was an icicle inside, but the bees were all alive and very active, and I placed the hive on a cloth at once and drove home. This box was quite water-tight. After a few days we had a thaw, followed by a severe frost; and shortly after all my bees were dead. There were plenty of comb and honey; box and all could not have weighed less than 30 lbs. or 40 lbs. Those now at work are in a box with three holes in the top, one half way up, besides the entrance-hole, and was one of some fourteen or fifteen boxes quite exposed; there is one or two in the apiary with knot-holes, and a fractured hole as it were dented out, and had been so for some years; over the top hole a small inverted box, not sealed down, and no cover overhead, or next to none, being so high that any rain or drift must find them out; though, perhaps, the top box would prevent any getting in at the top.

In another apiary, April 12th, the bee-keeper had buried or rather pitted two hives, and gave the following account:—Those exposed had consumed on the average 18 lbs. during the winter, those pitted 6 lbs. His method was as follows:—on the surface of the soil he placed some clean straw, on this a board on which to put his hives, building a roof over of boards, and closing the gable ends in the same way; then put on 10 inches of soil, but no moss or other packing between the boards and the hives. He intends to follow this plan with all late or badly-provided swarms. I am aware this is no new method; but from the poor account of bees in England, fancied they could devise some plan there to keep them at a low temperature, and sufficiently dry."—**F. H. WATTS, Woodstock, Canada West.**

[We have recently inspected a hive, the inhabitants of which perished during the winter (which even here has been no bad imitation of a Canadian one) under probably similar circumstances to those narrated by our correspondent. The hive was made of wood 1½ inch thick throughout, and sheltered from the weather by a loose covering of sheet zinc; it was perfectly air-tight, and contained fully 10 lbs. of sealed honey in good condition, so that starvation was out of the question. The bees were found clustered together between the combs, and were saturated with moisture. As North American winters are somewhat unusual in England, we must refer to American apirians for an explanation, which is given by Mr. Langstroth as follows:—"In March, 1856, I lost some of my best colonies under the following circumstances: the winter had been intensely cold, and the hives having no upward ventilation were filled with frost, and in some instances the ice on their glass sides was nearly a quarter of an inch thick. A few days of mild weather, in which the frost began to thaw, were followed by a temperature below zero, accompanied by furious winds; and in many of the hives the bees, which were still wet from the thaw, were frozen together in an almost solid mass."

Mr. Quinby explains the formation of icicles in a bee-hive in the following manner:—"If we examine the interior of a hive containing a medium-sized swarm on the first severely cold morning, except in the immediate vicinity of the bees we shall find the combs and sides of the hive covered with a white frost. In the middle of the day, or as soon as the temperature is slightly raised, this begins to melt, first next to the bees, then at the sides. A succession of cold nights will prevent the evaporation of this moisture; and this process of freezing and thawing, at the end of a week or two will form icicles, sometimes as large as a man's finger, attached to the combs and the sides of the hives."

"Upward ventilation" by means of orifices in or near the top of the hive is Mr. Langstroth's remedy; and this accounts for the fact which appears to puzzle our correspondent—viz., that hives ventilated by means of "knot-holes," &c, escaped the calamity which befel his own "water-tight" box.

Mr. Quinby winters his bees by inverting the hives in a dark room, whilst Mr. Langstroth gives full particulars of a German mode of wintering bees in what he calls a "bee-clamp," which is almost identical with the one described by our correspondent. Either of these methods may probably be followed with advantage during the severe winters of Canada and other northern countries, but will seldom be found necessary in our own more genial climate. See "To Correspondents" for answers to other queries.]

BOTTLE-FEEDING FOR BEES.

HAVING given fully 2 cwt. of food to my bees during last autumn by means of the bottle, I cannot concur in "A RENFREWSHIRE BEE-KEEPER'S" statement as to its being "a slow process." I used pint bottles with mouths of the size of a shilling, and found that every stock would appropriate two bottlefuls in twenty-four hours. If this rate of progress be not quick enough for our go-a-head Northern friends, I would suggest the use of Lazenby's wide-mouthed pickle-bottles, and feeding through a two-inch aperture. These bottles hold about a pint, and a strong colony would probably empty one in three or four hours, so that half-a-dozen pounds a-day might readily be administered to each hive.

Whilst on this subject, I may point out an error into which many others besides your correspondent have fallen with respect to the "constant dropping" of food from an inverted bottle. This supposed fact is wholly imaginary, as may readily be proved by experiment. Even pure water in a wide-mouthed pickle-bottle tied down with a piece of cap-net, will remain perfectly suspended without a drop falling after being placed in an inverted position.—**A DEVONSHIRE BEE-KEEPER.**

VARIETIES.

THE RASPBERRY JAM TREE;

OR STINKING ACACIA (OF CENTRAL AND WESTERN AUSTRALIA) AND THE GUM WATTLE, OR FRAGRANT ACACIA OF SOUTH AUSTRALIA.

In my journey into Central Australia (starting from Adelaide), I noticed a species of Acacia growing in the dry, stony beds of some of the creeks (lat. 31° south and long. 141° east), the blossom of which yielded such a putrescent odour that it has received the name of the "stinking Acacia."

The leaves yielded no sensible smell when fresh, but having cut down a few small branches, and placed them in the shade, I noticed that in forty-eight hours they gave out a strong, unpleasant odour, something like rotten cabbage. I had some branches in my tent, in which the temperature varied from 100° to 110° Fahr., and as at the same time the air was intensely dry it would appear that the odour is not easily eliminated.

A singular contrast was, however, exhibited in the wood, which, instead of partaking of the unpleasant smell of the blossoms or the leaves, was agreeably fragrant.

On my return to the settlements I found that this species of Acacia, though unknown in South Australia, Melbourne, or New South Wales, was known in Western Australia as the "Raspberry Jam Acacia," from some supposed resemblance in the fragrance of the wood to the odour of that well-known preserve. The wood has obtained the colonial name of "Raspberry Jam Wood," and the specimens from the Swan were very superior in fragrance to those from Central Australia. It is of a dark colour, very similar in appearance to Rosewood, very heavy and sunk in

water like a stone, and so hard when dry as to turn the edge of a saw or chisel.

The gum is probably, due to the presence of a small portion of oil, as is the case with sandal wood, only not so *richerché*, and it remains yet to be seen if it can be turned to profitable account by the perfumer. Let us suppose that essential oil of "Raspberry Jam Wood," or some other extract could be obtained, it would not be a particularly pleasant perfume; but that does not militate against it, for the same may be said of musk, ambgris, and many others when pure.

The contrast between the odour of the blossom of the Raspberry Jam Acacia and the blossom of the well-known Gum Wattle *Acacia decurrens*, is very remarkable. The former is sickly and almost as fragrant as an old oil-bag stump; the latter is most agreeable and delicious—yes, it is most sweet. Many of the valleys to the South of Adelaide every year at the season of blossoming returns, are redolent with the exquisite fragrance. This fragrance is, however, entirely in the blossoms, for the wood and leaves are scentless.

The Wattle or fragrant Acacia has been destroyed in nearly all the settled districts for the sake of the bark. That it might be profitably cultivated is beyond a doubt. 1st. It yields gail berries of great utility in many branches of commerce. 2nd. A most valuable perfume. 3rd. A gum similar to gum arabic. 4th. The bark is much valued by the tanner. 5th. It might be cultivated on land which also could be used for pasturage. 6th. The seed might be turned to some account. The seed is in pods similar to peas. Cockatoos are very fond of them. I noticed flocks of the beautiful rose-breasted cockatoos feeding off the seeds of the Raspberry Jam Acacia in Central Australia, and the white cockatoos in South Australia used to come in great numbers as regular as the season, and gorge themselves with the seeds of the Gum Wattle. I used to vary my dinner, which, from there being no fresh meat to be had, was chiefly of salt pork, with a roast of these fellows; but I cannot say much in their favour, even with the recommendation of an Australian appetite.

The gum of the Fragrant Acacia is used as an article of food by the aborigines. I have used it myself, and advised its use by others when hard pressed, and found it extremely nutritious. It requires some little cooking and bolting to get it down; for otherwise you may get as hungry while eating as if eating walnuts. The natives would eat 2 lbs. to 3 lbs. at a sitting.

The gum is the most valuable product, considered as an article of commerce. Some that I sent to England as a speculation realised £60 per ton, and a portion £63 per ton. The bark realised £15 per ton. My agent, however, advised me that those prices could not be maintained. As the gum is four times the value of the bark, and is yielded annually, while the bark can only be obtained once (for the tree dies), it reminds one of the fable of killing the goose. A party of men and boys out "barking" would destroy a belt of Wattles a mile in length in a week, and they make no distinction as to whether they are growing on Crown or purchased land, so long as the owner is not located on it.

The gum is used by manufacturers to give an apparent thickness and superior quality to their goods; also by confectioners and many others. A wholesale stay-maker told me that it cost him £150 per annum for gum arabic (which, after all, is chiefly obtained from Africa) merely to thicken and finish ladies' stays. The Australian savage eats the gum fresh and pure. Young England consumes it a varnish or polish on his gingerbread and buns.—LOUIS PIESSE, *Calcutta*.

RIMMEL'S PERFUME VAPOURISER.—There are many contrivances in use for fumigating and perfuming private apartments, sick-chambers, and public meeting-rooms; and many of them are not only in some instances offensive, but positively injurious. There is generally a coarseness and crudeness in the composition of all perfumes emanating from direct combustion, and hence the burning of pastilles, resins, and woods, is accompanied in many cases with a heavy, dull fragrance, which is both oppressive and disagreeable to many. In the apparatus before us, and of which we furnish the annexed representation, there is no such objection. Mr. Rimmel, the eminent perfumer, has here invented an appliance which most effectually charges the atmosphere of the largest apartment with any perfume that may be required, and in such a way as to be at once agreeable and refreshing. The apparatus consists of a bronzed urn raised on a tripod stand, and with a spirit lamp beneath it. In the inside is a vessel containing the perfume which it is intended

shall be used, and this vessel is placed over a water-bath, the steam from which, passing through a curved tube in the perfume vessel over it, distributes the perfume in vapour from the top of

the urn, and it is then diffused throughout the apartment. We have used this apparatus, and can speak from experience of the simplicity of its action, and of the delightfulness of its operation. We can imagine how refreshing in any apartment, whether it be a ball-room, or a chamber of sickness, would be the pungent fragrance of Rimmel's vinegar, emitted by the Perfume Vapouriser. It is not only a useful article, but an ornamental one, and might well find a place in any room of any residence.

EVENTS OF THE SEASON.—We saw a young Woodcock, half grown, on Thursday last. We hear of young Blackbirds, and the Rooks are very strong.—B.

OUR LETTER BOX.

COLDS IN POULTRY (J. G. P.).—We recommend you to use stimulants freely. There will always be violent colds while we have easterly winds by day, and hard frosts every night and morning. Acting on the old principle that prevention is better than cure, we are careful at these seasons to have the bottoms of beer, and drainings of wineglasses carefully saved in order to soak therein all the crumbs and crusts. These, with a little addition, enable us to give a good stimulating meal twice every day to those that seem most to require it.

GAPES IN CHICKENS (A Devonshire Subscriber).—No easily applied remedy is known. We have often recommended a little sweet oil to be injected upon the worms by means of a small syringe. The disease generally occurs in fowls of weakly constitutions, and as a preventive chalybeates are effective. A small quantity of green vitriol (sulphate of iron) dissolved in their water is beneficial.

GOLDEN-SPANGLED HAMBURG EGGS (F. S.).—The egg shells being "very thin," is the cause of their being broken, and, then, on wadding the hens partially eat them. It is the way to teach them to do so. We suspect your hens are too well fed. Give them a dessert-spoonful of castor oil, less stimulating food, and less food of any kind; also, have some limy rubbish thrown down where they can have access to it freely.

TURBITS WITH CRESTS (G. Winchester).—You must have overlooked the reply to Mr. Oates, in last week's *JOURNAL OF HORTICULTURE*. I prefer the head of a Turbit without either turn crown or point, as I consider it detracts from the peculiar form of the head. By a reference to all the older works on Pigeons, it will be found that no mention is made of the turn crown by the writers, and their plates show them smooth-headed. I fancy the crest has been introduced by the Germans, who add it to the Barb, Fantail, Powder, Tumbler, and even the Carrier; but such addition is not in accordance with our notions of purity of breed.—B. P. BRENT.

GREY PARROT SICK (Caroline).—Change its food. Omit hempseed and bones; continue the sopped bread; give it nuts; and let it have water and a tepid bath daily if it will accept it voluntarily. Some water slightly warmed in a soap plate is sufficient.

RABBITS (A New Subscriber).—If you buy our No. 642, you will find how to make an enclosure; and in the whole of our last volume there is information desirable for you to possess as to their management. Any kind will thrive in such an enclosure, so you must be guided by whether you require them for their flesh or their fur. The best of flooring for a hen-house is gravel rammed hard, and covered 3 inches deep with sand. Bricks are the worst of flooring for a hen-house.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 67° and 44.3° respectively. The greatest heat, 82°, occurred on the 26th in 1853; and the lowest cold, 29°, on the 25th in 1839. During the period 139 days were fine, and on 99 rain fell.

ARRANGING FLOWERS IN BOUQUETS AND VASES.

Make your home beautiful—bring to it flowers.

Plant them around you to bud and to bloom;

Let them give life to your loneliest hours.

Let them bring light to enliven your gloom.

Make your *own world*—one that never has sorrowed—

Of music, and sunshine, and glad summer in.

A *home world*, whose forehead care never has furrowed.

And whose cheek of bright beauty shall ever be fair.

Make your home beautiful—gather the Roses

That board up the sun-shine with exquisite art;

Perchance they may p'nr. as your darkest day closes,

That soft summer sunshine down into your heart:

If you can do so—oh! make it an Eden

Of beauty and gladness—remember 'tis wise;

'Twill teach you to long for that home you are needing,

That heaven of beauty beyond the blue skies!

Make your home beautiful—sure 'tis a duty—

Call up your little ones—teach them to walk

Hand in hand with the wondering Angel of Beauty—

Encourage their spirits with Nature to talk.

Gather them round you, and let them be learning

Lessons that drop from the delicate wings

Of the bird and the butterfly—ever returning

To Him who has made all these beautiful things.

INTRODUCTORY CHAPTER.

WE were reading the other day of the wide-spread beauty of this grand old earth, the wonders of the starry skies, the courses of the winds and the science of the fleeting clouds. There lies the ocean with its forest growth of sea-weeds, its wonderful streams and currents, and its deep blue waves. And there are, again, the strange old relics of ages past, wonderful and strange to look upon and to read about—the delicate thin shells, broken by a touch, and yet preserved in stony dress to unveil to us now the life of those far-off years.

Thinking of all these things, and of all the living wonders and living beauties that surround us in the world we live in, one pauses, and the thoughts arise—What did such beauty come for? Surely such gifts must bring some duties? Is Beauty truly a shadow, a trace of the great Creator who alone is perfect Beauty? Are we, poor little crawling insects of a day, intended here to learn to know the better and the more to love the shadow of that Beauty, which, when our wings have at last come to us, the remaining eternity will perchance be spent in worshipping and loving?

But by what little tiny ways we have to learn these beautiful great lessons! It would seem ridiculous if it were not so true. But as it is, one's mind goes on quite naturally to think how a little more of this abundant beauty could best be brought into our English homes: for surely anything is a blessing by which we may make

them brighter. How is it, one wonders, that England beyond all other lands should so abound in gardens? Flower-grown walls and bowery green trees, waving Lilacs and Laburnum tresses, tasselled Larches and ever-green shrubs, throwing such a pleasant shade about her country homes.

Perhaps it just is that flowers *are* such homely things, that English hearts are sure to love them, and English homes to have them; and indeed I dare say that their pure sweet ministrings, the memories they recall, and the thoughts they bring, *do* help in no small degree to make homes what they are.

But flowers are such joyous things. We want them more—much more. We want them to come and bring their sweet fresh brightness with them into many more rooms, even in crowded towns, for peace and gladness are so much wanted there; and though both joy and sorrow lead to heaven, joy is yet surely the sweetest path to go by.

And so it was that I began to think how strange it was that there should be everywhere so much beauty scattered all around us, and yet that often in the very heart of home we should so little find that beauty and that brightness which lovely flowers may give: in the sitting-room, for instance, or the boudoir, or the library, or—it's no use my trying to follow out where "*the den*" may be: everybody knows which is their own home's pleasant room; and I put it to their conscience. *Has* it many flowers? and *are* those flowers artistically arranged?

"Yes," says some one, "the girls do it very well. Flowers always do look nice, you know. Besides, I don't believe there is much arranging. I never see them look nicer than just slipped into the basket as they first come in."

I wonder how many have noticed this to be a fact?

The flowers are actually more artistic in their rough effect than they are afterwards when three of the young ladies have worked for an hour at arranging them in their vases.

I think it is, that in the basket they are roughly grouped in masses as they are gathered. In the vases quantities are mixed up—different and inharmonious colours, and mutually dulling shades thrown all together, making a sadly broken and even dingy whole.

At any rate, it is quite clear that while French bouquets and German wreaths are so very charming—while there is not a toilette without its appropriate flower *parure*, so very far lovelier than jewels for the young—while there is no family fête in Germany without its graceful door wreaths and its garlanded picture frames and coronals of flowers—while in Russia the custom of flower-decked tables has reigned till at last it has taken the very English "*mahogany*" by storm—all this time what in-door floral fashion have the English set?

I know their gardens are lovely and their homes loaded with the sweetest flowers; but I really hope it is not with them as with those people who are so fond of dogs in their proper places.

So now the Editors of this Journal, having for a long time taught the world what to grow and how to set about it, intend also to give a lesson on how to manage and arrange what has been fairly grown.

The same rules apply to most things. The "dinner Russe" is, perhaps, just now most interesting—a painful subject too, considering its expense and its fragile material, so very frail and fleeting.

But, what a delusion it is to fancy that so many flowers are wanted! A good many are, of course, on a good-sized table; but I wonder how many flowers in each group are used which actually make more flowers needful instead of themselves assisting to fill up!

This sounds very odd and strange I dare say; but it really is a fact, that the fewer colours and the fewer shades there are, the fewer are the flowers which will fill the vase.

And then, again, in mixed flowers such very common little things come in, for it is an expensive mistake to fancy so many flowers and such grand kinds are wanted. For the hair, too, and for the dress, how well I remember those charming simple little *gracieuses* wreaths—Ivy, or evergreen Rose leaves, or Myrtle, and beautiful dark or silvered foliage, a few Snowdrops, or some drooping Deutzia—that little flower like a delicate white Ribes, a few pale blue Harebells, single Hepaticas, Scillas, or bells of waxen Hyacinths, Pansies again, and Roses, Azaleas amongst the fairest, and the exquisite Chinese Honeysuckle, and little sprays of Lilac.

I need not, however, say any more, for this is only the introduction, and if I fairly begin I shall never stop.

Yet, before proceeding to more precise directions and particulars, I must illustrate what I have been saying by

A BOUQUET DESIGN FOR MAY.

It may seem premature to give a design before one has yet hardly begun to explain the plan of working. But one can easily choose a very simple specimen, and this one I think most persons could manage well. I saw one day a very lovely design; it was entirely formed of Violets—double white and purple, made up with a few green leaves arranged in the outer circle.

This is certainly rather sombre, but still I may describe it, because by substituting brighter flowers for the white and purple Violets it may easily be made gay.

Whatever flowers are used should be, however, *small*. Hyacinth bells, for instance, mounted singly on stalks of wire, would do very nicely. Hepaticas and white Violets would answer beautifully, and so would double Peach and double Cherry blossoms: these being, perhaps, the very best of all.

It is necessary to be very exact about the shape and flatness. To effect this a tin funnel without a tube—or a card formed into such a shape—is very useful. A stiff bushy piece of green should be placed in the centre of the circle, the top being as flat as possible, so as to be just level with the lip of the funnel, and the stalk being long and firm.

Other pieces of green should now be arranged round this, keeping them very flat, and binding each one down to the first by a long piece of strong white wool. The leaves of sweet-scented Geranium, Myrtle, Lily of the Valley, and Scarlet Geranium especially, do excellently for filling up this space, just as if one was making a common green nosegay.

If small round flowers are to be used entirely, the foliage should be also of the smallest and neatest kind.

Having filled the frame with green, the flowers which have been till the last moment kept in water in the dark should be mounted on stalks, which need not be very stiff if wire is used in mounting, only it is necessary to be careful that it does not cut through the flower-stems.

For the actual design that which comes from the outside into a point at the centre looks very well. I think six points are, perhaps, the best. Six wedges—that is to

say, pointing towards the middle, which looks extremely well filled by a fine Camellia or Azalea; but if it is not the same flower as that which composes the bouquet generally, it must be a perfect match in colour, and being alone it should be in itself a good and well-shaped flower. In this place a white Rose would do well.

The lines must be very exactly kept, and then when the flowers are all arranged, and tightly bound together, the whole should have a frill of white Deutzia, or Lilies of the Valley with Fern leaves or some other pretty and not too fragile foliage.

A bouquet so made will keep fresh for a long time, especially if it is protected from cold and draughts of air.—E.

(To be continued.)

SPRING FLOWERS AND BEDDING PLANTS.

WHEN I asserted, very recently, that the best spring flower for beds, rounds or ribbons, among all the races of the Primrose family is the Yellow Polyanthus "Good Graciously," I ought to have said as I meant, only the best yellow kind; for there is another Polyanthus that must come before it, not in merit, perhaps, but in right of the principle of edging beds of strong colours with neutral colour of the greatest force, as with white or whitish variegated-leaved plants, or low kinds with white flowers. We all know these take the first turn round a bed, or along the front of a ribbon line, and no one disputes the priority, even if he does not admit the necessity for it. A strong yellow flower, on the other hand, is objected to for front work by the great patrons of the present planting system: therefore it is that this Polyanthus will never reach the first place on a spring ribbon, for there is a white Polyanthus equally good, if not better, to come first; as I do not expect to be able to get a real scarlet Polyanthus or Primrose quite free from spots, the second place, or row, and must of necessity reserve for it to cut the white from the yellow Polyanthus. None of the three have clean clear colours. The eye of the first two is much alike: therefore, whatever the eye of the third or scarlet is to be, that kind must take the middle distance; and so "Good Graciously" is to be third on the list after all. Even supposing the three were of equal merit, I cannot push my seedling farther than the third best place in this class of flowers.

In truth, till I had seen eleven other kinds of yellow Polyanthus and one kind of yellow Primrose, I could not say exactly in which row to place the yellow. I have all these now in my own garden, thanks to the donors. I passed my word that Punch Geranium and Shrubland Rose Petunia would be out of cultivation before "Good Graciously" Polyanthus, and I took no merit for raising it, as I distinctly said; and knowing that self praise is no recommendation, when I praise myself, or my doings and sayings, or my way of thinking, I do so for the good of my readers. My reward is, the more readers I make: therefore I study to please and instruct the greatest numbers. But when I differ from a reader in matters of taste, as between two or more kinds of plants, or more ways than one of disposing of them, I never hold an argument on taste, nor enter upon logic to prove who is right and who is wrong about fashions and fancy plants; and that is an answer to a gentleman who writes about me and prefers a Cowslip to the best yellow Polyanthus.

Dr. Herbert in the "Journal of the Horticultural Society," left us on record (Vol. 1847, page 96), that he considered "the natural forms of *Fuchsia virgata*, *gracilis*, *globosa*, and discolour so superior to the mixed shapes produced by gardeners, that he had been unwilling to deteriorate them by intermixture. He was the best cross-breeder that England yet produced. The best cross-breeder from among the Scottish people is Isaac Anderson Henry, Esq., of Edinburgh, or near it; and he says, this same month of May, that "he was never so much in love with variegated foliage as to seek to promote or preserve it much in any thing." But the fashion of this world will not stop to ask what an English or Scotch cross-breeder may think of this or that style of plant, or if a wilding is preferable to a cross, or a cross to a natural sport; and I am sorry to confess that I, too, go too much after the fashion of this world in fancy dress, and dressing, both in-doors and out, up-stairs and down. I always persuade the rising generation of gardeners to avoid strife and wrangling as much as possible, and to live in good will and good fellowship with all their kind and its varieties, and in my turn I endeavour, as much as in me lies, to set them the example.

From this day it is quite safe to remove all kinds of *spring Crocuses* out of the flower-borders, and to put them in thinly by the heels, as we say, in a place of reserve, there to remain to the middle or end of August, when they ought to be taken up and sorted, and to be replanted, according to their sizes, in a thin bed with a hard bottom, where they are safe enough to Christmas, or until the borders are again ready for them. But the rule which holds good for standing Crocuses will not do for Crocuses that are transplanted when in leaf. Such as are thus removed early to make room for summer things will lose their leaves sooner than those not disturbed; but this early losing of the leaf is not to be taken as a sign to give up watering them altogether. And here is where a great many people have been wrong altogether, for I proved the fact by direct experiments two years back, and forgot to say so this time last year. If the roots and tubers of a transplanted Crocus, which loses the leaves earlier than usual, are allowed to get dry as soon as others that were not transplanted, that is more against them than the transplanting. The reason of that seems to be this: The removal gives a certain check to all plants, least to bulbs, the early fall of the leaf being the effect of the check. Most plants and all bulbs can carry on the process that was not quite finished by the leaves for certain periods after the leaves are gone, provided they are placed in a suitable condition to carry out the process—that is, that they are not allowed to get quite dry nor very wet for some weeks after all traces of the leaves are lost. Every bulb that blooms from February to the middle of May is under this law and rule, or may be brought under it with all safety, provided the ground is not awamped by too much watering, nor yet allowed to get dry for the first month after transplanting. The best place, therefore, for such things to be removed to would be a deep, light, well-drained border on which the sun does not shine but in the mornings and evenings; or if it did not shine upon it, that would be preferable to one exposed to the direct influence of the sun.

There is a little silvery and very small-leaved plant which I mentioned last autumn from Kew, which, I am now fully persuaded, will make one of the most useful edging or first line in a ribbon. I had a handful of cuttings of it late in September, put them under a common hand-glass all through the winter without any more covering; and they have all freely rooted, and last week I had them transplanted 3 inches apart on the back of a narrow border on which I have all the yellow and white Polyanthuses, and where the sun does not touch till the afternoon. I can see quite plainly that a gardener might keep the same plants for six or seven years before they were too large for that purpose, and that 2 inches or 3 inches apart would be sufficient room for them the first season from cuttings, and an inch or a little more would be all the extra room they would need yearly till they were 6 inches across the head and 4 inches or 5 inches high, if they were cut two or three times during the growing season, just as box-edging is clipped, only that it might be done with the knife. It is the very old Lavender Cotton plant, the *Santolina chamaecyparissus*, which, if it were taken up at the end of October, and planted in any sheltered place every year would soon be able to resist the hardest frost in our climate. It should be in the nursery lists of bedding plants for next year.

Another plant, which I mentioned once or twice, is *Stokesia cyanea*, a very strong herbaceous plant of the Composite order, to bloom in the centre of a bed of China Asters all through the autumn. It is yet in the wild or raw state; but assuredly will sooner or later run into double flowers, and then you shall have a race of blue dahlia-like plants at last. It may require the same indulgence as the chrysanthemum to get it to seed; but even should it require to go to Jersey, or Naples, or Algiers, or to Natal, or Sydney to get it to produce double and sportive seedlings, I would not give up the chance it offers to the cross-breeding florist, because, like the dahlia, it would be everybody's plant, and once it is domesticated it would probably increase much like the chrysanthemum. I would also have all the new and old Pyrethrums, and seed them also, and see what industry and perseverance could work out of them. What all Composite flowers seem to require to break them into double flowers and into various shades of colour is very high cultivation for a succession of seasons, and using fresh seedlings every year, but still keeping two or three of the originals until you have them at command, like bulbs which make new sets of roots annually; and the way to do that is to remove them twice a-year into fresh and highly-manured earth, first in October and

then in April in each year, and cutting back every one of their roots to the size of a nice handy ball. This you will call the bulb, and by causing fresh roots so near home, and so often in such stimulating pasture, if the nature of the change is not beyond the art of man, you, or some one you may know somewhere abroad, will be sure to succeed.

In 1850 or 1851 an amateur in one of the eastern counties sent me a cut bloom of a large blue double Cineraria which he said he meant to send up to the fashion office, and which, I think, will be in the volume of THE COTTAGE GARDENER for the time; but ten years are a long time to get into fashion. The other day I saw a second double Cineraria, of which you will hear with this. Why, then, should not all the Cinerarias—if, indeed, they be not rather Senecios—be double. We have had a good run of single ones, and unless something more is done to them, they, too, must go into the same lists as herbaceous Calceolarias—that is, they will be a most useful fashion for private use, like the dressing-gown and slippers; but who would go to a show in that fashion?

I have thought long since that one might get a run of most useful bedding flowers out of *Coreopsis Drummondii*. I have seen it repeatedly half-double, and with two rows and three rows of florets full as the outside ones, and it needed not but so much more extra stimulus to throw up every bottom of the florets which form the disk or centre part of daisy-like flowers, as fully developed as the two or three rings round the outside. Strange it is, that no Composite flower has yet been seen on the centrifugal-force system—that is to say, offering to turn double from the centre of the disk instead of following the lead of the ray florets. Depend upon it that comes not of chance; and if ever you discover the law which governs the finishing up of the florets of Composite flowers from the circumference instead of from the centre of gravity, or by the centrifugal force, you will never have a bull's eye flower in your garden, nor want a large balance at your bankers. Of course you are aware that in all the rest of the flowers the leader goes from the very centre, whether it goes upwards or sideways. Just think of that and how you could alter it.

D. BEATON.

ORCHARD-HOUSE TREES.

I HAVE recently received the enclosed interesting letter about orchard-house trees, which, as I have permission from the writer, you may think worthy of insertion in your columns.—T. R.

"My orchard-house trees were never in such health and vigour as they are now. I shall have a fine crop of Peaches, Nectarines, and Plums; but although I could have more than a hundred each on several of my trees, I do not expect that the average will equal that of last year, when it exceeded fifty all round. But the great attraction for visitors to my orchard-house is the rich, beautiful foliage with which almost every branch is clothed, I may say from the graft to the summit, and the preparation that they are making for next year's crop. I manage them nearly all on the spur system, rarely letting up a new branch from below, and in this way I am less crowded; besides the vigour of the tree is not expended in producing too much wood.

"Last year I was more disposed to the pyramidal form, and although I have been successful with that mode of culture, and have at present half a dozen pyramidal pictures I shall not abandon the 'bush,' which I have found to be useful and productive. Where there is but the one straight stem the sap rushes up with too much force to the top, and causes a number of strong shoots there, while on the lower part of the tree they are weaker and less abundant. But I have arrested this effect to some extent by the use of what I call the tourniquet, which consists of lead wire wound tightly round the stem at distances of about a foot each.

"A propos of *pyramids*, you are quite right in saying that the term is wrong, and that we should call them cylinders. In a little French work, from which I have obtained a good deal of information, by Bulret et Thouin, this method is called '*taille en chandelle*,' and which, while it is admitted to have certain advantages, is termed *assez disgracieuse*. I have not any pyramidal Plum trees, but I mean to cultivate Plums in that way next year.

"Do you remember a Peach that you sent out some years ago as the 'Early York,' and for which you apologised to your

clients, stating that you had been imposed on by getting from America two consignments of the Early York, one of which turned out to be (said you) a worthless late Peach, and you then offered to send, gratis, the true Early York to all those who had got the spurious one? I got the spurious one, but I am far from thinking it worthless. It forms the most beautiful of orchard-house trees. The blossom is different from that of all other Peaches, exquisitely cupped, a charming colour, lasts double the time of other blossom, and every one produces a fruit. Last season this small tree had about two hundred Peaches, which I thinned down to one hundred, and even that was far too many. Yet they looked so pretty I could not bring myself to remove more. They ripened in November, and although not rich nor very sweet, they were pleasant and refreshing; the best of them were used with a little sugar, and the small ones made into a pie. I cut down the two largest branches of this tree last autumn, and those that remained are now full of young fruit, and making excellent spurs for next year.

"You sent a true Early York in the batch of seven which you presented to me some time ago, and I found it to fulfil all the promises you made. It bore forty-two fine fruit last year.

"A great deal of the success of the orchard-house depends on getting the sorts adapted for that mode of culture. For instance, those that make short joints and are prolific, such as the Grosse Mignonne, and Galanée Peaches, Elruge, Violette Hative, Downton, and other Nectarines; but the Noblesse, George IV., and trees of that class, are too long in the joints and of straggling growth. My best tree for this year is a Downton Nectarine on which there are a hundred fruit well set, and most of them larger than a hazel nut. The tree is in a tub and not much more than 3 feet high. I shall also have a grand crop on my potted trees of Green Gage, Orleans, Cox's, Jefferson's, Guthrie's Late Green, Mirabelle, and a large purple Plum the size of a duck's egg, name unknown, and an excellent one for preserving and a very showy fruit. The only idle Plum tree in my orchard-house is a Purple Gage, which I do not think will have more than a dozen.

"Outside, some of the Pears are almost idle, but some of them promise very well. My four trees of Gans'fs Bergamot double worked are all loaded. I find this sort when double worked to be perfectly hardy and a never-failing bearer, and I have one of them now as an open espalier.

"Beurré Bretonneau is very hardy and bears freely, but the fruit does not soften. Duchesse d'Orléans does not bear at all, ditto Urbaniste; and those I mean to expel or cut down and work them with a better sort. I had no idea until this year that Cherries made such interesting trees in the orchard-house. They are beautiful when in bloom and when the fruit has coloured; the slender branches of one of my pyramids, a large-leaved tree, I think Belle Magnifique, bend down so gracefully and the foliage is so fresh and healthy, that it looks quite charming, and I can now understand, what I did not before, why you wished to have a Cherry-house.—JOSEPH MEADOWS, *Wexford.*"

PLANTING OUT BEDDING PLANTS—EFFECTS OF POTATO-STEMS BEING FROSTED.

It may reasonably be expected by this time that the winter is over, and we may be able to make a fair estimate of our available strength in the bedding-stuff line. The fine weather of April was highly favourable to the hardening off of the young stock, and, doubtless, those that are situated like myself, with a limited stock of pots and boxes, have felt an irresistible temptation to put some of it into their summer quarters. And finding the barometer moving downward a little yesterday morning, and the wind shift to S.E.S., I reckoned upon a favourable change of weather; and as I was cramping other things for the want of boxes—and to save time, trouble, and room, I box everything I can, and make boxes out of everything that fulfils in my way—I at once put out a good batch of Scarlet Geraniums, yellow Calceolarias, purple and white Petunia, with the following annua's in small bunches between the plants, taken up with a flat trowel and the roots undisturbed and some of them showing bloom. *Collinsia alba* and bicolor, *Lunanthus Douglasi*, *Nemophila insignis* and *grandiflora*, and *Venus' Looking-glass*. I reckon that at the latest a fortnight's fine weather will bring them into full bloom and fill up the beds, and should the weather prove bright and sunny they will shade the roots of the other plants till they get fairly established.

But to-day (May 8th), has thrown a gloom over yesterday's work. Snow fell from about half-past four in the morning till mid-day, and at one time more than an inch deep on the ground, and the probability is, a frost to-night; but having secured them as well as I can with yew and fir branches, I trust a slight frost will not injure them: Hitherto having been very fortunate with them, not having lost a score out of more than six hundred cuttings of *Calceolarias*, sorted kinds, and kept in a Cucumber-frame throughout the winter. All the cuttings of Geraniums, with the variegated and others, kept in pots during the summer have been kept with scarcely any loss, kept in a home-made cupboard-kind of place with a glass front with a blue a little above the floor; but the old Scarlet Geraniums although taken up before the frost touched them have nearly all died in the same place, it being the only place I could keep them secure from frost.

I should be glad if a few of the readers of THE JOURNAL OF HORTICULTURE would assist me a little in trying to prove the effects of frost on the Potato. Some few years ago I had a row at the end of a bed up much earlier than the rest, and, in consequence, were cut down to the ground with the frost, and their being a different kind to those in the bed, made me remark more particularly the effect at lifting time, and I rather unexpectedly found them equal to the others. Since then I have yearly tried the same experiment with the same result, and in the year 1859, on the 1st of April, there were 12° of frost. I then had a Peach-border several inches high, but were entirely cut off. They recovered that and were again cut off, one portion the size of a Russian mat I covered and were not frosted at all. Yet, at lifting, I could not discover the least difference whatever—they were as early and equal in quantity and in quality. Now, there will be numerous opportunities of trying the experiment this spring, and by putting a few sticks to those that have been frosted and making a memorandum to that effect so as to bear it in mind at lifting time, the thing can easily be settled by giving the result in THE JOURNAL OF HORTICULTURE. Most gardeners not having pits for their earliest crop can bear testimony to the trouble of covering up their earliest Potatoes till after the fear of frost, and at a time, too, when there is so much other work to do; so that if that portion of labour can be saved it will be worth the trouble in proving.—THE DOCTOR'S BOX.

ROYAL HORTICULTURAL SOCIETY.

MAY 14TH.

FRUIT COMMITTEE.—H. G. Bohn, Esq., in the chair. A letter was read from Mr. Spencer, of Woodok, recommending a Local Committee for the county of Wilts, which was approved, and Mr. Spencer appointed Chairman and Convener. A paper on the physical condition, and geological structure of the county of Oxford was received from Mr. Bailey, of Nuneham, Chairman of the Oxfordshire Local Committee, and read before the Committee, and the thanks of the Meeting were given to Mr. Bailey.

The prizes offered by C. Wentworth Dilke, Esq., and W. Wilson Saunders, Esq., were then taken into consideration, and one of those offered by Mr. Dilke, of the amount of £5, was unanimously awarded to the seedling Pine Apple raised by Mr. Oates, gardener to Lord Leigh, Stoneleigh Abbey, Kenilworth. That offered by Mr. Saunders, of the amount of £5, stood over for consideration at next Meeting, when Ingram's Hardy Prolific Muscat Grape is expected to be exhibited in better condition than it was shown during the past season. The remaining prize of £5, offered by Mr. Dilke, was not awarded, but carried forward to next year.

The seedling Strawberry Eclipse exhibited last year by Mr. Willis Reeve, of Canewdon, near Rochford, was again brought forward, and fully maintained the reputation it acquired last year, when it was considered a valuable forcing Strawberry, possessing a high Pine flavour; it was awarded a First-class Certificate. Three seedling Strawberries, raised by Capt. Trevor Clarke, were brought from the Society's garden at Chiswick, one of them a black variety with a deep blood-coloured flesh, and another of a pale scarlet colour; but neither of them was considered desirable as new varieties. A collection of six sorts of forced Strawberries were sent from the garden by Mr. Eylea, which showed that the earliest forcing variety is May Queen, and the second earliest is Black Prince; but Black Prince is the most highly flavoured, and decidedly the preferable variety. All the others, including Keens' Seedling, which was flat and rapid, and Richard II. and Highland Mary, which were very acid, were

inferior in flavour to Black Prince, and all were inferior to Eclipse.

Mr. Robertson, of Linside, near Paisley, offered a prize at this Meeting of £2 for the best, and £1 for the second best three pots of Wizard of the North Strawberry. There was only one exhibition, and the first prize was accordingly awarded to the exhibitor, Mr. Cunningham, gardener to the Lord Bishop of London, Fulham Palace. It was the opinion of the Committee that Wizard of the North as exhibited is not a desirable variety for forcing, being small, inferior in flavour, and very acid. Mr. Cunningham exhibited a seedling Strawberry, called Courteen Hall Seedling, which had no particular merit to recommend it. A dish of very large Oranges was received from Sir Travell Phillips, and the sort proved to be the Pernambuco Orange.

Calville Blanche Apple grown in the orchard-house at Chiswick, proved of very fine quality, and with very tender flesh, as did also Baddow Pippin, but it was too much shrivelled. Mr. Gardiner, of Lower Ealington Park, Stratford-on-Avon sent a very nice collection of well-kept Apples, which received a Certificate of Commendation. Captain Trevor Clarke exhibited a collection of the dried seeds of Kidney Beans.

FLORAL COMMITTEE.—The approach of the exhibition season, and the consequent demands on the time of all who are the usual contributors to these reunions, made the supply of flowers for adjudication exceedingly scant. The great Crystal Palace Show on Saturday, to be followed by the Royal Botanic on Wednesday the 21st, tax pretty well the energies of the growers; besides, any who have any novelties to bring forward will rather keep them for either of those days, when they will be seen by a much larger number of persons. And that is a point which enters somewhat restrictively into the minds of those on whom necessarily the commercial value of a plant must hold a large place; and this will ever, I believe, be found to weigh down even the stamp of the Floral Committee. Perhaps when the new gardens become really thrown open to the public, and these *petite* flower shows become the "correct thing" to be present at, it may be different, but at present the paucity of visitors is an obstacle to growers. There were, however, a few interesting subjects.

Mr. Kendall, of Stoke Newington, sent in a number of very dwarf small-flowered Cinerarias of various shades of colour, and a small *double* one of the same character. As florists' flowers these were utterly worthless, and I therefore rigid florists will scout them; but though pretty strong in that way myself, there seemed to be good reason why the double one should receive the award that it did—a Label of Commendation. It is true, as was observed, that it was very like a double Senecio, but then one does not get a double Groundsel at this time of the year; and although florists' varieties of Cinerarias may be shown as dwarf, yet that is only by the dint of very severe training and infinite trouble, whereas this was shown in its natural state. Something of the same kind may be said with regard to some Pansies exhibited by Messrs. Downie, Laird & Laing, of Edinburgh (from whence the box came) and Stanstead Park, Forest Hill. There were very fine blooms of some of the best varieties out; and along with them two, rather limsy and a little rough, but very remarkable in appearance—one a white with an immense eye, and the other a reddish-crimson, very much after the French style but better shaped: both very attractive, and perhaps the forerunners of an entirely new strain. As a florist I should, of course, condemn them; as a lover of flowers, I should look hopefully at them. A Complimentary Ticket was awarded.

From Messrs. Veitch & Son came a basket of Mrs. Ponsonby Moore—a free-blooming decorative Geranium (figured in the "Floral Magazine") very pretty, and possibly a good bedding one, though this remains to be proved. For this a Label of Commendation was awarded. The same gentlemen also exhibited a basket of *Petunia imitabilis flore pleno*—a very striking variety, something in the way of Madame Henri Jacotot, white, with broad bands of mauve colour. It is said to be a continental variety. A First-class Certificate was awarded to it, as, independently of its colour, it was an excellent grower, and for pot culture very desirable. Also a very beautiful Australian *Pimelea*, most justly named *Elegans*. It is one of the small-growing varieties of the genus, and is like a beautifully white transparent ball with orange points all over; this appearance being caused by the pollen on the anthers. For this a First-class Certificate was awarded. Messrs. Veitch & Son also exhibited some seedling plants (with dried specimens of the foliage) of species of the new *Coniferae*, which were sent home by Mr. J. G. Veitch from Japan, including *Retinospora pisifera*,

obtusa, &c. The thanks of the Committee were awarded for these.

From Messrs. Lee, of Hammersmith, came *Arundo* conspicua—somewhat like the Pampas Grass, but not so fine; the New Zealand Grass (*Syrinchium versicolor*), and *Lauropus Gardneri*. These, with some Azaleas from the Society's garden, formed the only features worth noticing.

GENERAL MEETING.—A General Meeting was held on the same day at 3 o'clock, Right Rev. the Lord Bishop of Winchester, V.P., in the Chair, when a large number of ladies and gentlemen were elected Fellows; among whom were Right Hon. Lord Chesham, Lord Rokeby, Lady Rokeby, Earl of Cawdor, Lady Elizabeth Sturley, Lieut.-Col. T. F. Elphs, Sir C. Lindsay, Sir Henry Rawlinson, Earl of Lanesborough, Frank Crossley, Esq., M.P., &c.

A ballot took place for plants to be distributed.

The Council have appointed a Fine Arts Committee for the decorations of the Gardens, South Kensington, with statuary, vases, &c. It consists of His Royal Highness the Prince Consort, Earl Somers, Earl Ducie, Lord Taunton, Sir Coutts Lindsay, Mr. Wentworth Dilke, Mr. Henry T. Hope, Professor Westmacott, and Mr. Sydney Smirke. The Committee met at the Gardens on Monday and Friday last. His Royal Highness in the chair.

Among the prizes to be competed for at the forthcoming grand exhibition of flowers and fruits, June 5th and 6th, on the occasion of the opening of the Gardens, South Kensington, we notice four prizes of £10, £5, £3, and £2, given by one of their Vice Presidents for the best three groups of fruit and flowers arranged "for the decoration of the dinner table." The prizes are open to all comers, and the articles may be exhibited in baskets, vases, &c., of any material; *beauty in the arrangement* being the test of merit. Ladies are specially invited to compete, and the Council have appointed the following ladies to act as jurors:—The Countess of Shelburne, the Countess of Ducie, Mrs. Holford, Lady Marian Alford, and Lady Midilton.

These are, we believe, the first prizes of the kind given at the Society's Shows, and we anticipate a good deal of interest from the combination of the designs of the numerous competitors.

EFFECTS OF LAST WINTER ON PLANTS IN ENGLAND.

(Continued from page 123.)

THE columns of the various gardening publications are, week by week, re-echoing the devastations of the past winter. It may, therefore, interest many to know that in the extreme south-west of England such casualties have not occurred. Instead of detailing the individual trees or shrubs that have been either injured or died, it will be sufficient to say that *Araucaria brasiliensis* has stood wholly unprotected in Mount's Bay, and that it has not suffered in the slightest degree. *Verbenas* and shrubby *Calceolarias* that were bedded out in some instances have survived; and *Camelias*, *Magnolias*, and the tenderer *Rhododendrons* exhibit no sign of injury from frost, although the violence of the gale in February has, in some exposed situations, damaged the foliage; but from this, like the laurels and bays that were similarly circumstanced, they are rapidly recovering.

The early Potatoes are already coming in from Scilly and some sheltered places on the cliffs between Penzance and the Land's End. On the low grounds, a very heavy dew on the night of Saturday, the 11th of May, followed by severe hoarfrost in the morning, has cut down several acres; but the general crop looks well. Since the 7th of April rain has fallen, but on one day (April 30th) and then only for about forty minutes. The ground therefore requires moisture: but when it comes it will doubtless develop the Potato disease, of which signs have already showed themselves.

The late Broccoli planted in July and August last are growing vigorously, but show no signs of flowering, although their season is now almost gone by. There are many acres in this neighbourhood where this is the case.

The seeds of Onions, Carrots, and Lettuces came up very few and far between; but this is more attributable to the wet season of 1860 than to the present dryness.—W., near Penzance.

PERHAPS the plants that look now perfectly uninjured may be

set down as hardy, and the enclosed list may interest you. My place is fourteen miles west of Dublin, and 300 feet above the sea level, on a cold, stiff soil, and stiff gravelly subsoil on limestone. Every tree in my list, except those to which notes are appended, is flourishing, and not the least injured by the frost which for a long time last winter varied from 12° to 20° Fahr. Laurustinus has been much injured; Roses cut down, but mostly shooting from their roots (even including Adam); Hollyhocks almost all killed. The list of Pines may, perhaps, serve as a guide to those planting in calcareous soils where the Spruce and Larch do not generally succeed. *Pinus insignis* is by far the most rapid grower, and most beautiful here; next *nobilis* and *Nordmanniana*.

TREES PLANTED ELEVEN YEARS.

Pinus insignis, 26 feet high, spread of branches 15 feet, girth at 2 feet from ground 4 feet. *P. insignis*, 27 feet high, girth at 2 feet from ground, 3 feet. *P. strobus*, 24 feet high, girth at 2 feet from ground, 2 feet 6 inches. *P. excelsa*, 18 feet. *P. monticola*, 12 feet. *P. Pallasiana*, 16½ feet. *P. rigida*, 15 feet.

Picea cephalonica, 15 feet. *P. nobilis*, 15 feet.

Cedrus deodara, 15 feet.

Taxodium sempervirens, 20 feet, girth at 2 feet from ground, 3 feet.

Cupressus thurifera, 20 feet.

Araucaria imbricata, 15 feet.

TREES PLANTED FROM TEN TO FOUR YEARS AGO.

Cupressus Lawsoniana and *McNabiana*; *Thuia Lobbii* and *gigantea*; *Thuiopsis borealis*; *Cryptomeria Lobbii*; *Wellingtonia gigantea*; *Abies morinda*; *Picea Nordmanniana*; *Libocedrus chilensis*.

SHRUBS.

Desfontainia spinosa (alive, but not flourishing); *Weigela rosea* and *amabilis*; *Berberis Darwinii*; *Philæa buxifolia*; *Eurybia alpina*; *Griselinia littoralis*; *Myrtus apiculata* (injured not killed); *Eucallonia macrantha*; *Spiræa*, var.; *Hibiscus syriacus*.—CHARLES W. HAMILTON, *Hamwood, Dunboyne*.

CULTURE OF THE GRAPE VINE.

(Continued from page 61.)

PLANTING.—The cultivator having procured his Vines either from a nursery or by propagating them himself till they are fit to plant, the next operation will be the important one of planting. For walls the best season is autumn, only the border should be covered with short litter to keep out the frost. The planting of Vines in a greenhouse or stove should be deferred till March, but even then the Vines ought to be planted before the buds begin to swell.

The mode of planting for out-door culture will be somewhat different to that for in-door culture. The roots should be more spread out right and left, because each Vine will eventually cover more space—that is, there will be more space between each Vine. In the sketch of the Vine-border, at page 41, the roots are shown running across the border—the right plan, because each Vine only has the breadth of each light for its pasture; but on a wall in the open air each Vine trained, as I shall show presently, will have a space of 18 feet broad for its roots to ramble in: hence the roots should be spread laterally as shown by this sketch (fig. 1).

Fig. 1.

In planting choose a dry day and turn out the ball entire, and pick out from among the roots all the soil. Then carefully uncoil and disentangle the roots, and remove a thin stratum of the soil sufficient in length and breadth to contain them. Then spread them out at equal distances, and cover them with a compost of loam and leaf mould in a rather dry state 2 inches thick. Some authors recommend decayed tan to cover the roots with; but I

do not recommend that substance to come near the roots, for when it is very rotten it has a soapy, muddy appearance, and often in that state it is poisonous to the young fibres. When all are planted fork over such parts of the border as may have been soddened by treading upon, and cover the border with some warm stable-dung sufficient to give out a milkwarm temperature. To be quite perfect the border, after the Vines are planted, should be protected from heavy rains, either with tarpauling or shutters just raised above the dung resting upon a long piece of wood next the houses, and on a similar piece on the side of the border next the walk. Where the Vines are planted inside, this covering may be dispensed with the first year: but when the roots have pushed through outside, then this shelter ought to be applied as soon as the wood is ripe.

So far my remarks are general, and apply to all Vines excepting such as are grown in pots or in an orchard-house. It is time now to enter into the various ways by which the Vines are grown, commencing with

VINES IN THE OPEN AIR ON WALLS.

In the south of England we often see the walls of cottages and even better-class houses covered with a Vine, which in favourable seasons ripens very nice fruit, or, at least, would do if better managed. Every bunch the Vine shows is allowed to grow and not a berry is thinned out, and too often not a summer's shoot is shortened—and the training, why, it is just haphazard. With such management it is no wonder that the fruit is not so good as it might be if better attended to. If a Vine is planted against a house, the main stem should be trained straight up, and side shoots taken from it to cover the spaces between the windows. Young wood should be laid in annually and brought close to the wall to ripen it, and no more should be allowed than is necessary to produce fruit. All laterals should be stopped at the first joint, and cut away as the wood ripens. Regular attention to this stopping and training, and allowing no more than one bunch to each shoot, and as soon as the berries are as large as peas to thin out at least half of them, would give the fruit a chance to swell larger and ripen better.

It is, however, to the culture of the Grape Vines on a garden wall facing the south, that I now wish to draw the attention of the cultivator. The management, after the border is properly made and the Vine planted, consists chiefly in pruning and training. The best mode of training is, first to obtain two shoots from the two buds left on when the Vine was planted. Let them be trained upright at 2 feet apart (fig. 2). Then in the autumn bring those two shoots down, and train them horizontally at about half a yard from the ground (fig. 3). Pinch out all the buds excepting three on each side of the main stem. Let these six shoots be trained perpendicularly close to the wall (fig. 4). If all has gone on well those shoots will run up to the top of the wall that year.

Fig. 2.

Fig. 3.

During the summer stop all the laterals at the first joint, and stop each leading shoot when it has reached to the top of the wall. See that the shreds are not too tight, or they will strangle the shoots. If the summer is dry give the border a good soaking of water

Fig. 4.

once a fortnight. The distance from shoot to shoot should be 2½ feet. If they are closer the wood will not ripen so well, and if wider there would be a loss of space. By the end of September or middle of October the leaves should be turning yellow and the wood brown. As soon as the first frost has brought off all the leaves, then proceed to prune the Vines. My mode of

pruning the Vine on walls, whether in or out of doors, is the alternate long-rod system. By this plan a regular supply of good fruit-bearing wood is secured, and, besides that, the method is simplicity itself, and is regular and neat in appearance. In the autumn the Vines will have two shoots to bear fruit, and these should be pruned to nearly the top of the wall. Two others will be cut down to a bud close to the main horizontal stems. These will send up shoots to be trained between the fruit-bearers, whilst the two end shoots should be trained down in the same line as the horizontal ones.

In the third summer the last year's horizontally-trained shoots should have all the buds rubbed off excepting two on each. These two should be 2½ feet apart and trained to the wall should reach the top of it that year. This year's growth will cover the space of wall each Vine should fill—that is, there will be four fruit-bearing upright shoots, and four shoots to bear fruit the

Fig. 5.

following year (fig. 5). In the autumn those that have borne fruit should be cut down, and the others left nearly their whole length to bear fruit.

Should the trees when four or five years old show anything like weak growth, then remove a portion of the surface soil, and add a sufficient quantity of fresh compost to renew and sustain their strength. Occasional waterings with liquid manure will greatly assist their growth, and will help to swell off the fruit. The finest fruit will always be near the top of the wall, but I have had very good bunches and berries about halfway down.

The following are good kinds to grow against a wall in the open air:—Early Black July, Esperione (black), Royal Muscadene (white), White Dutch Sweetwater, Black Hamburgh, and Verdelho (green).

T. APPLEY.

(To be continued.)

CRYSTAL PALACE FLOWER SHOW.

THE first Flower Show of the season was held at the Crystal Palace on Saturday last, and although we missed some of the great exhibitors who usually contribute towards the effect of these floral gatherings, there was, nevertheless, a very excellent display. The close proximity of the grand opening at Kensington Gore has caused many of the large exhibitors to keep their plants back for that occasion, and hence the dearth so apparent of those floral mammoths which we were accustomed to see on those occasions.

We must reserve till next week our critical observations on the Exhibition, merely remarking that the Roses in pots of Messrs. Lane, were as usual very fine, as were those also of Mr. William Paul, of Waltham Cross. The Pelargoniums and Cinerarias of Mr. C. Turner, also formed a prominent feature; and among the Fruit, we remarked the fine exhibitions of Mr. Hill, of Keele Hall, of Mr. Henderson, of Trentham, and of Mr. Stewart, of Chatsworth, from the midlands, who seemed to have the best of the great stakes. All we can do at present is simply to append the prize list, leaving our observations till next week.

TWENTY STOVE AND GREENHOUSE PLANTS (in flower).—First and Second, Mr. B. Peed, gardener to T. Tredwell, Esq., St. John's Lodge, Lower Norwood.

TWELVE STOVE AND GREENHOUSE PLANTS (in flower).—First, Mr. John Green, gardener to Sir E. Antrobus, Bart., Lower Cheam. Second, Mr. R. Baxendine, gardener to W. A. Smallpiece, Esq., Millmead House, Guildford. Third, Mr. William Cuthbert, Nursery, Barnet.

EIGHT STOVE AND GREENHOUSE PLANTS (in flower).—First, Mr. H. Chilman, gardener to Mrs. Smith, Ashstead House, Ashstead. Second, Mr. Wm. Kaile, gardener to the Right Hon. Earl Lovelace, East Horsley Towers, Ripley. Third, Mr. Thomas Page, gardener to W. Leaf, Esq., Streatham. Fourth, Mr. James Tegg, gardener to Baron Hambro, Southampton. Extra Prize, Mr. Osman Rhodes, Nursery, Sydenham Park.

SIX STOVE AND GREENHOUSE PLANTS (in flower).—First, Mr. Thomas Page, gardener to W. Leaf, Esq., Streatham. Second, Mr. Charles Smith, gardener to Arthur Anderson, Esq., Norwood. Third, Mr. William Kaile, gardener to the Right Hon. Earl Lovelace, Ripley. Fourth, Mr. H. Chilman, gardener to Mrs. Smith, Ashstead. Fourth, Mr. John Green, gardener to Sir E. Antrobus, Bart., Lower Cheam. Extra Prize, Mr. R.

Baxendine, gardener to W. A. Smallpiece, Esq., Millmead House, Guildford.

TWELVE FINE-FOLIAGED AND VARIEGATED PLANTS. —First, Mr. Charles Hunt, gardener to Miss Burdett Coutts, Highgate. Second and Third, Mr. G. Young, gardener to W. H. Stoe, Esq., Dulwich Hill. Fourth, Mr. G. H. Bunney, Stratford. Fourth, Mr. J. Smith, gardener to Coles Child, Esq., Bromley.

SIXTEEN ORCHIDS (of Exotic Species, in flower).—First, Mr. Robert Stone, gardener to J. Day, Esq., Tottenham. Second, Mr. B. Peed, gardener to T. Tredwell, Esq., St. John's Lodge, Lower Norwood.

TEN ORCHIDS (of Exotic Species, in flower).—First, Mr. Edward McMoreland, 29, Adelaide Road, Haverstock Hill. Second, Mr. Robert Stone, gardener to J. Day, Esq., Tottenham. Third, Mr. Thomas Page, gardener to W. Leaf, Esq., Park Hill, Streatham. Fourth, Mr. S. Woolley, Cheshunt, Herts.

SIX ORCHIDS (of Exotic Species, in flower).—First, Mr. Charles Penny, gardener to H. H. Gibbs, Esq., St. Dunstan, Regent's Park. Second, Mr. G. H. Bunney, Stratford. Third, Mr. Edward McMoreland, 29, Adelaide Road, Haverstock Hill. Fourth, Mr. Robert Stone, gardener to J. Day, Esq., Tottenham.

TEN GREENHOUSE AZALEAS. —First, Mr. Charles Turner, Royal Nurseries, Slough. Second, Mr. John Green, gardener to Sir Edmund Antrobus, Bart., Lower Norwood. Third, Mr. S. M. Carson, gardener to J. C. Sim, Esq., Nonsuch Park, Cheam. Extra Prize, Mr. Thomas Page, gardener to W. Leaf, Esq., Streatham. Extra Prize, Messrs. James Ivory & Sons, Dorking and Reigate.

SIX GREENHOUSE AZALEAS. —First, Mr. Charles Turner, Royal Nurseries, Slough. Second, Mr. Thomas Page, gardener to W. Leaf, Esq., Streatham. Third, Messrs. James Ivory & Sons, Dorking. Third, Mr. Charles Penny, gardener to H. H. Gibbs, Esq., St. Dunstan, Regent's Park. Fourth, Mr. B. Peed, gardener to T. Tredwell, Esq., Lower Norwood. Extra Prize, Mr. Charles Smith, gardener to Arthur Anderson, Esq., Norwood.

EIGHT GREENHOUSE AZALEAS (New kinds).—First, Messrs. James Ivory & Sons, Dorking. Second, Mr. Charles Turner, Royal Nurseries, Slough. Third, Messrs. James Ivory & Sons, Dorking.

EIGHT CAMELLEAS. —Second, Mr. B. Peed, gardener to T. Tredwell, Esq., Lower Norwood. Third, Mr. O. Rhodes, Nursery, Sydenham Park. Fourth, Mr. Thomas Page, gardener to W. Leaf, Esq., Streatham. Fourth, Mr. H. Chilman, gardener to Mrs. Smith, Ashstead.

SIX TALL CACTI (species or varieties of, in flower, large plants).—First, Mr. John Green, gardener to Sir Edmund Antrobus, Bart., Lower Cheam. Second, Mr. Wm. Young, gardener to R. Barclay, Esq., West Hill, Highgate. Third, Mr. A. G. Ashman, gardener to C. W. Major, Esq., Burntwood Grange, Wandsworth Common.

TEN ROSES (in pots, distinct kinds).—First, Messrs. Lane & Son, Great Berkhampstead. Second, Mr. Wm. Paul, Waltham Cross. Third, Messrs. Paul & Son, Cheshunt.

SIX ROSES (in pots not exceeding 8 inches in diameter).—First, Mr. Wm. Paul, Waltham Cross. Second, Mr. Charles Turner, Royal Nursery, Slough. Third, Messrs. Paul & Sons, Cheshunt. Fourth, Messrs. Lane and Sons, Great Berkhampstead. Extra Prize, Mr. Wm. Kaile, gardener to Rt. Hon. Earl Lovelace, Ripley, Surrey.

TEN PELARGONIUMS (distinct varieties, in pots, not exceeding 8 inches in diameter).—First, Mr. Charles Turner, Royal Nurseries, Slough. Second, Messrs. J. Dobson & Sons, Woodlands Nursery, Isleworth.

EIGHT FANCY PELARGONIUMS (distinct varieties, in pots, not exceeding 8 inches in diameter).—First, Mr. Charles Turner, Slough. Second, Messrs. J. Dobson & Sons, Isleworth.

SINGLE SPECIMENS OF NEWLY-INTRODUCED, EXTREMELY RARE, OR BEAUTIFUL PLANTS, IN OR OUT OF FLOWER, BARY OR EXOTIC. —First, Mr. S. B. Williams, Nursery, Holloway. Second, Mr. W. Bull, King's Road, Chelsea. Third, Mr. G. Rogers, gardener to Capt. Jefferys, R.N., Foot's Cray. Third, Mr. G. H. Bunney, Stratford. Three equal Fourth Prizes, Mr. W. Bull, King's Road, Chelsea.

SIX PLANTS OF CIERARIAS (in pots, not exceeding 11 inches in diameter). —First, Mr. Charles Turner, Slough. Second, Messrs. J. Dobson & Sons, Isleworth. Third, Mr. James Burley, Nursery, Limsfield, Surrey. Fourth, Mr. W. Lovesey, gardener to J. J. Fry, Esq., Baston Hayes, Bromley.

MISCELLANEOUS. —Prize, Mr. G. H. Bunney, Stratford. Prize, Mr. Wm. Paul, Waltham Cross. Third, Mr. James Burley, Limsfield. Fourth, Mr. H. Lavey, gardener to E. A. DeGrave, Esq., Fitcham, Surrey. Fourth, Mr. William Bull, King's Road, Chelsea. Fourth, Messrs. F. & A. Smith, Dulwich. Extra Prize, Mr. Charles Turner, Slough; Mr. John Porter, Paragon Nursery, Brixton Hill. Highly Commended, Messrs. F. & A. Smith, Dulwich.

CUT FLOWERS.

TWENTY-FOUR TULIPS (dissimilar).—First, Mr. Charles Turner, Slough. Second, Mr. B. H. Betteridge, Milton Hill, near Stevenage, Berks. Third, Mr. Nathaniel Norman, 98, Crescent Road, Plumstead. Fourth, Mr. James Batten, Brook Street, Clapton.

TWENTY-FOUR PANSIES. —First and Second, Mr. J. James, gardener to W. F. Watson, Esq., Isleworth. Third, Mr. Edward Shenton, Heaton Park Nurseries.

FRUIT.

Class A.—PINE APPLE (single fruit of any kind).—First, Mr. Andrew Stewart, Chatsworth. Second, Mr. Thomas Page, gardener to W. Leaf, Esq., Park Hill, Streatham. Third, equal, Mr. George Cameron, Goodwood Gardens, Sussex; Mr. James Drewett, gardener to Mrs. Cubitt, Denbies, Dorking. Fourth, Mr. T. Page, gardener to W. Leaf, Esq., Park Hill, Streatham. Extra, Mr. Walter Davies, Starch Green, Middlesex.

Class B.—GRAPES (Black, single dish).—First, Mr. William Hill, gardener to Ralph Sneyd, Esq., Keele Hall, Staffordshire. Second, Mr. Archibald Henderson, Trentham, Staffordshire. Third, Mr. George Wortley, gardener to Admiral the Hon. P. Cary, Norwood.

Class C.—GRAPES (White, single dish).—First, Mr. Charles Powell, gardener to Dr. S. Newington, Titcher, Sussex. Second, Mr. John Embery, gardener to A. Moss, Esq., Chadwell Heath, Essex. Third, equal, Mr. F. W. Durrant, gardener to the Hon. Col. Duncanson, Waresley Park. St. Neot's, Hunts; Mr. T. Page, gardener to W. Leaf, Esq., Park Hill, Streatham. Fourth, Mr. Henry Baker, gardener to J. Harrison, Esq., Belgrave, Leicestershire. Extra Prize, Mr. Thomas Bailey, gardener to T. T. Drake, Esq., Shardeoles, Amersham, Bucks.

Class D.—GRAPES. —First, Mr. William Hill, gardener to Ralph Sneyd, Esq., Keele Hall, Staffordshire. Second, Mr. H. Baker, gardener to J. Har-

rison, Esq., Belgrave, Leicestershire. Third, Mr. Montgomery Henderson, Cole Otton Hall, Ashby-de-la-Zouch, Leicestershire. Fourth, Mr. Thomas Frost, gardener to E. L. Betts, Esq., Preston Hall, Aylesford, Kent. Extra Prize, Mr. Alexander McKenzie, Bristol Nurseries; Messrs. Spary & Campbell, Queen's Graperies, Brighton.

Class E.—PEACHES, (single dish of one kind only).—First, Mr. Archibald Henderson, Trentham, Staffordshire. Second, Mr. Montgomery Henderson, Cole Otton Hall, Ashby-de-la-Zouch. Third, Mr. Thomas Dawson, gardener to Viscount Palmerston, Broadlands, Romsey, Hants.

Class F.—NECTARINES, (single dish of one kind only).—First and Second, Mr. Archibald Henderson, Trentham, Staffordshire.

Class G.—MELONS, green-fleshed, single fruit).—First, Mr. James Taplin, gardener to Lord Hatfield, Teddesley Park, Stafford. See nd, Mr. Thomas Frost, gardener to E. L. Betts, Esq., Preston Hall, Aylesford, Kent. Third, Mr. James Eastone, gardener to Sir J. Duckworth, Bart., Wear House, Exeter.

Class M.—MELONS, (scarlet-fleshed, single fruit).—First, Mr. James Eastone, gardener to Sir J. Duckworth, Bart., Wear House, Exeter. Second, Mr. Thomas Frost, gardener to E. L. Betts, Esq., Preston Hall, Aylesford.

Class J.—CHILLIES (Single dish).—First, Mr. Archibald Henderson, Trentham, Staffordshire. Second, Mr. Archibald Henderson, Trentham, Staffordshire. Third, Messrs. Thomas Jackson & Sons, Royal Gardens, Hampton, Court.

Class K.—STRAWBERRIES, (single dish in fifties).—First, Mr. R. Smith, Richmond, Twickenham. Second, Mr. Thomas Bailey, gardener to T. T. Drake, Esq., Shaddecks, Amersham, Bucks. Third, Mr. Joseph Gillham, Mogden Lane, Isleworth.

Class L.—STRAWBERRIES, (three kinds, twenty-five of each).—First Mr. R. Smith, Richmond Road, Twickenham. Second, Mr. Charles Turner, Royal Nursery, Slough.

Class M.—STRAWBERRIES (In pots, six plants).—First, Mr. W. Kalle, gardener to the Right Hon. Earl Lovelace, Ripley. Second, Mr. C. Smith, gardener to A. Anderson, Esq., Norwood. Third, Mr. Willis Reeve, Apton Hall, Canewdon, Redford.

Class N.—MULCH PLANTS.—Prize, Mr. F. W. Durrant, gardener to the Hon. Col. Duncombe, Waresley Park, St. Neot's, Hants.

DEATH OF PROFESSOR HENSLOW.

WE regret to have to announce the death of the Rev. John Stevens Henslow, Professor of Botany in the University of Cambridge, who died on the 16th inst., at Hitcham, Suffolk, of which place he was rector since 1837.

The late Professor was born at Rochester in 1796, being the eldest son of J. P. Henslow, Esq., by his wife Frances, daughter of Thomas Stevens, Esq. Having imbibed the elements of education at Rochester School, he was sent to St. John's College, Cambridge, where he graduated in 1818, as 16th wrangler. In 1821 he took the degree of M.A., having previously taken holy orders.

On the death of Dr. Edward Daniel Clarke in 1822, Mr. Henslow was elected his successor in the Professorship of Mineralogy. The majority of the members of the Senate, however, voted for the Rev. Thomas Jephson, of St. John's College; but the heads of colleges refused to admit him to the office, on the ground that he had not been duly nominated by them. Mr. Jephson's adherents thereupon applied to the Court of King's Bench for a mandamus, but the case was not proceeded with, in consequence of Mr. Jephson having, *pendente lite*, been indicted for a crime *hæreticæ Christianis nominandum*. The question was not finally decided before Mr. Henslow had ceased to hold the professorship.

In 1825 he succeeded the Rev. Thomas Martyn in the Professorship of Botany, which he continued to hold to the time of his death.

The Government presented him, in 1837, to the rich rectory of Hitcham, in Suffolk. This benefice is worth £1179 per annum, besides a residence. Professor Henslow's scientific attainments were very great, nor were his antiquarian acquisitions by any means inconsiderable.

His principal works are:—"A Geological Description of Anglesa," "The Principles of Descriptive and Physiological Botany," "Le Bouquet des Souvenirs," "Report on the Diseases of Wheat," "Account of Roman Antiquities found at Rougham," "Dictionary of Botanical Terms," "Flora of Suffolk" (conjointly with E. Skepper); besides numerous papers in scientific periodicals.

By his wife Harriet, daughter of the Rev. George Jenyns, of Bottisham Hall, Cambridgeshire, he has left issue a son, the Rev. Leonard Ramsay Henslow, born in 1831; and, we believe, other children.

THE ILLUSTRATED BOUQUET.—This, the Twentieth Part, or quarterly issue, is very rich in selections of kinds of plants for the flower garden, and equally so in illustrations of the choicest new flower-garden plants of the sections of Pelargoniums, or Geraniums, Fuchsias, and Dianthus. The first plate, 46, re-

presents *Rhododendron aureum magniflorum*, one of the best of the large yellow *Rhododendrons*, under which "is an enumeration of the most commendable kinds of that race of *Rhododendrons* for general cultivation," and the way to obtain them by means of cross-fertilisation. The next plate represents a full-sized view of Princess of Prussia, a "*Horseshoe Pelargonium*." This is the second and the best kind of *Globe Scarlet Geranium* that has yet appeared worthy of the name of *Compactum*—a brilliant scarlet shaded with orange and crimson. Under this richly illustrated bedder we have selections from *Zonale* or *Horseshoe-leaved Geraniums*, from the *Compactum* section of *Horseshoe*, from the plain-leaved or *Inquinans* section of *Scarlet Geraniums*, and from the "*Nosegay* section or varieties from *Fothergillii*," of Sweet's. On the next plate is the new Hybrid *Perpetual* or *Mule Pink*, *Dianthus hybridus multiflorus*—the best flower-garden plant that has yet appeared in *Dianthus*; we have seen it growing in a pot and there is no mistake about it. It is very bushy or stocky at the bottom, and has a profuse head of branched flower-stems (not scapes, which are the flower-stalks only of bulbous plants), and it blooms continuously from June to November, unless it is stopped by a severe frost. The best single *Mule Pink*, and the double form of it, which was raised by Captain Trevor Clarke, stood with us last winter without getting the top of a leaf browned. All this breed seem as hardy as the mountain *Pink*. The next plate represents an extraordinary yellow, large-leaved bedding *Geranium*, called *Cloth of Gold*, which is said to be of a fine, "free, dwarf, bushy habit;" "also, specially marked by its exceedingly dense-leaved habit throughout the summer and winter." Following this are given selections of variegated *Geraniums* for all the various purposes they are useful for. The last plate is of three of Mr. Banks' best *Fuchsias*, black, blue, and white, or the nearest tints to them, *Black Prince*, *Prince Leopold*, and the *White Lady*, all reflexed and as large as *crinoline* can stretch them. Then are given lists and selections of *Fuchsias* new and old and for various purposes. This is one of the most useful parts of this valuable work.

REPORT ON THE GARDEN PEAS,

GROWN AT CHISWICK DURING 1860.

By ROBERT HOGG, LL.D., F.R.H.S., Secretary to the Fruit Committee.

(Continued from page 116.)

42. Monsieur SoyerTURNER.

The plant is not a strong grower, and produces a simple stem 2 feet to 2½ feet high, bearing from ten to twelve pods, which are single and double in about equal proportions. Foliage deep green, and much blotched. This season the pods filled very unequally, and rarely contained more than four or five perfect Peas; all the others being abortive or imperfectly developed. Ripe seed white and wrinkled.

Sown February 19th; bloomed May 29th; slatted June 16th; and ready for use July 10th.

This is decidedly a tender variety and ill-suited for such a season as the past; but it has all the character of an excellent sort, being very productive of pods, and the earliest of all the dwarf white Wrinkled Peas. In a warmer season it would doubtless prove a desirable second early in the Wrinkled class, to come in after *Advancer*. It was raised by Dr. Maclean, of Colchester.

43. Tall White Mammoth.

SYN: *Flanagan's Imperial* } FLANAGAN & SON.
Norfolk Marrow. }

Green's SuperbNOBLE, COOPER, & BOLTON.

Ward's IncomparableNOBLE, COOPER, & BOLTON.

Oxford TomSTUTTON & SONS.

Colton's LeviathanHURST & M'GULEN.

Champion of ScotlandLAWSON & SON.

This is a strong and vigorous grower, 6 feet to 7 feet high, and when planted thinly produces three or four lateral branches, which are almost as long and productive as the main stem. The foliage is very much blotched. The pods are from twelve to twenty-four on a plant, and are generally in pairs, of a bright green colour, containing on an average seven very large Peas, which are over half an inch in diameter. The ripe seed is white and wrinkled.

Sown February 19th; bloomed June 19th; slatted June 23th; and ready for use July 14th.

This is a very valuable *Pea*, producing an abundance of very large well-filled pods. The plant continues growing, blooming,

and podding, and it is not unusual in mild seasons to find it supplying an excellent dish of green Peas as late as Christmas.

44. Maclean's ProlificTURNER.

The plant is a free and rather vigorous grower, 2½ feet to 3 feet high, and with dark green foliage, which is very much blotched. The stem is simple and produces nine to twelve pods, which are generally in pairs, and were this season very unequally filled. They mostly contained from five to six well-developed Peas, all the others being either abortive or only partly grown. The ripe seed is white and wrinkled.

Sown February 19th; bloomed June 15th; slatted June 26th; and ready for use July 15th.

It will be seen that although this bloomed four days earlier than Tall White Mammoth, and was slatted two days earlier, it was not fit for use till the day after that variety was ready for gathering. In all probability had the season been warmer this would have proved itself an earlier and much more productive sort.

45. AllianceNOBLE, COOPER, & BOLTON.

SYN: *Eugenie*.

Plant with a free habit of growth, having a succulent stem, and rather light green blotched foliage. The stem is simple, 3 feet high, and produces from twelve to sixteen pods, which are generally in pairs, and are produced at every joint. They are not well filled, and contain only five to six good-sized Peas in each. The ripe seed is white and wrinkled.

Sown February 19th; bloomed May 29th; slatted June 16th; and fit for use July 16th.

This differs from Climax, only in having the ripe seed white. When first introduced it was a valuable acquisition as being a tolerably early dwarf white Wrinkled Pea, but it is now far surpassed in every way by several of Dr. Maclean's new varieties.

Shanley MarrowFRASER, RICHARDSON & GOAD.

This is a free and robust grower, 6 feet to 7 feet high. The stem is generally single, but also sometimes branched when the seed has been sown thin, and then it is furnished with two or three laterals which are the same height as the main stem. The pods are generally single, but occasionally in pairs, and are to the number of thirteen to eighteen on a plant; they contain five to seven very large Peas, some of which are more than half an inch in diameter. The ripe seed is white and wrinkled.

Sown February 19th; bloomed June 20th; slatted June 30th; and fit to be gathered July 16th.

British Queen is now an established variety, and justly esteemed as one of the best and most productive of the Tall Wrinkled Marrows. On a well-branched plant I have counted as many as thirty-one pods of all kinds, including those full grown and those just formed; and in a mild autumn it is not unusual for it to continue growing, blooming, and podding as late as Christmas. I do not see any material difference between this and Tall White Mammoth, with the exception that the latter is two days earlier; the plants are exactly similar in habit, and are equally productive.

WHITE POLYANTHUS.

THROUGH the kindness of a rev. gentleman in Norfolk I now possess the finest white Polyanthus in the world, and the most flowery Polyanthus I ever saw; it is at the same time the sweetest-scented kind that ever passed through my hand. When I opened the basket the room was soon filled with its delicious scent.

One expense, however, brings on another; and what I principally write this for is to make an ardent and very strong appeal to the kindness of all the kind people of the three kingdoms to hunt me out and to send to me, at my own expense, the most decidedly scarlet, or the nearest to scarlet, of all the Polyanthuses in cultivation. If I succeed in this effort, I have a notion that I shall be able so to dispose of the cream of the flock as to be able to put a "Good Gracians" spring-bed within the reach of all our people, and to bring up the Polyanthus to that point of public favour which it obtained when Lisbon was nearly swallowed up by the earthquake. It often appeared strange to me the earth never quaked under the florists for despising

pin-eyed Polyanthuses—the best eye to cross of all other eyes. Those which are not pin-eyed must have the throat of the flower cut open with some sharp instrument, to get at the pin-head and to dust it with the pollen.—D. BEATON.

OUR CULTIVATED SOILS.

THERE is certainly nothing in the whole gardening world that bears a more indefinite meaning than the word "loam." In many districts a first-class plantsman would apply that term to the most useful article he puts on the potting-bench; while in this neighbourhood (Staplehurst), the best bricks are made from what is locally termed "loam," and farmers and fruit-growers generally cover their grafting operations with the same material.

Now, it is needless offering any opinion as to which of the parties mentioned above are right, for both will claim to be so, although it is evident there is a wide difference in the materials to which they both apply one name: the only practicable way must be to qualify the term by calling one kind "an open friable loam," and the other a "stiff clayey loam;" for, be it remembered, Kentish men makes a difference between loam and clay, although, as I have just said, they make the best bricks of the former, its superior properties being its not shrinking so much in the fire, and retaining a better shape when taken out; and for grafting it has the same good property of not cracking so much as clay does.

Now, these qualifications indicate a certain amount of tenacity, but not exactly of that plastic description which a tough clay possesses. But as the making of bricks, drain tiles, and the like need not be entered into here any further than to explain the term "loam" as used in some places, we may next see in what sense it is generally used in gardening matters, promising in the first case that it will be best to qualify the term in such a way as to make the meaning understood by all.

In this I may say that I am only taking up a subject left unfinished by our late talented and respected fellow-writer to this Journal, Mr. Errington, whose last article, it will be remembered, was on "Soils, Earths, and Loam," and apparently only commenced with when Nature gave way.

LIGHT HAZEL LOAM.—This term is far from being so expressive as could be wished, for its constituent parts may differ as wide almost as the antipodes; but it is generally made use of to denote a loam mingled more or less with gravel, the colour being pale, and the substratum porous; but the quantity of sand in such a loam is not sufficient to entitle it to the term of a sandy loam or sandy soil. Many of the valleys in Hertfordshire possess a soil of this description, the hills being of chalk overlaid with a thin crust of rather a stiffish white loam, or soil differing in many respects from this. In a general way a light hazel loam produces good Wheat and Barley, and grass land adapted for sheep, but not for cattle; if not too much surcharged with water, Oak and Beech trees thrive in it; and most garden vegetables of the grosser-feeding kinds do well in it, excepting Celery and Asparagus. But so much depends on the substratum that it is difficult to form a correct judgment upon it; for if it be of a hungry or, perhaps, pernicious character, and the soil shallow, its fertility must be only of a secondary kind: this, however, is widely different where it rests on a bed of a contrary description.

A WHITE CHALKY LOAM.—This is the coating so many of our chalk hills have—some of them thickly covered also with stones of a flinty character. Such a soil is not adapted for many garden products. Early Peas, however, stand the winter well in it, and its being distasteful to slugs, seedling plants are raised with more certainty of success than in some other soils. But it is almost death to Rhododendrons, Calceolarias, and such plants as like a soil more or less impregnated with iron. But I believe many plants often grown in our greenhouses in a soil the reverse to this would do well in it—I mean the pea-flowering plants from New Holland and elsewhere. Witness the Saintfoin, Clover, Furze, Broom, Trefoil, and other plants often found wild on this soil, and compare these with the Polygala, Pimeleas, Coronilla, and other things, and see if there is not a great resemblance. I believe I am also right in saying that on a soil of this description plants will stand the winter best; but, on the other hand, they suffer sadly in a dry summer, and vegetables require both liquid and solid food in an extravagant degree to bring them to perfection. Filberts seem to do better here than any other fruit, yet it is not exactly the one this

capricious shrub requires; but as many trees, as well as herbs, have the knack of accommodating themselves to circumstances, we often see that good cultivation accomplishes good results even on a chalk hill.—J. ROBSON.

(To be continued.)

NEW AND RARE PLANTS.

BELOPERONE VIOLACEA (*Violet-coloured Beloperone*).

Nat. Ord., Acanthaceæ. *Linn.*, Diandria Monogynia. Native of New Grenada. Bears exposure in borders during summer and autumn on the Continent. Flowers purple.—(*Bot. Magazine*, t. 5244.)

PARITUM ELATUM (*Lofty Paritum*).

Nat. Ord., Malvaceæ. *Linn.*, Monadelphia Polyandria. This, which has also been called a Hibiscus, produces the *Cuba Bast*, so well known to gardeners. "It is a noble tree (50 to 60 feet high) with ample, cordate-rotundate leaves and large flowers, both in bud and when expanded of a bright brick-red colour." It is native of Jamaica and Cuba. Its wood is much valued by cabinetmakers, being in colour a dark-variegated green, often called "green ebony." The negroes make superior ropes of the bark, and a mucilage that has been employed advantageously in dysentery, is obtained by boiling water from the young shoots and leaves. The inner bark also yields that beautiful network fibre known as "Cuba Bast."—(*Ibid.*, t. 5245.)

TILLANDSIA RECURVIFOLIA (*Recurved-leaved Tillandsia*).

Nat. Ord., Bromeliaceæ. *Linn.*, Hexandria Monogynia. Sent to Kew Gardens from Panama, by W. D. Christie, Esq. Flowers white, with rose-coloured bracts.—(*Ibid.*, t. 5246.)

MALORTICA SIMPLEX (*Simple-leaved Malortica*).

Nat. Ord., Palmaceæ. *Linn.*, Monœcia Hex-Dodecandria. Native of Costa Rica. Flowered at Kew in February of the present year. It is a slender, graceful, dwarf palm.—(*Ibid.*, t. 5247.)

DRACENA BICOLOR (*Broad-leaved two-coloured Dracena*).

Nat. Ord., Asparagineæ. *Linn.*, Hexandria Monogynia. Native of Fernando Po. Flowered at Kew in February of the present year. It is a stove plant 1 foot high. Flowers white, bracteoles bright purple.—(*Ibid.*, t. 5248.)

DENDROBIUM LINGUEFORME (*Tongue-leaved Dendrobium*).

Nat. Ord., Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Port Jackson and Moreton Bay. Not at all showy. Flowers ivory-white, expanding here in winter in an ordinary greenhouse. "Leaves very curious, thick, fleshy, and almost resembling pseudo-bulbs." It grows well on a piece of wood.—(*Ibid.*, t. 5249.)

ABIES DOUGLASI.

ON the 2nd inst., a flagstaff of unrivalled height and symmetry, made of the Douglas Pine (*Abies Douglasi*), from Vancouver Island, was erected on a rising ground in the arboretum of Kew. It is the gift of Mr. Edward Stamp, a gentleman largely concerned, in connection with Messrs. Bilbe & Co., of Nelson Dock, Rotherhithe, in the timber trade of British Columbia. It is only justice to Mr. Stamp and Mr. Bilbe to state that this is the second spar which they have presented. The first measured 118 feet long, 14 inches in diameter at the base, and 4 inches across at the summit. It was the largest pole adapted for a flagstaff that had ever been known in Europe, and it was sent as a specimen of the tree in question, smoothed and made ready for elevation, through the liberality of Mr. Bilbe. Unfortunately it sustained two accidents. On its way up the river it was cut in halves by a steamer, but taken back by Mr. Bilbe and repaired at his yard; and again, in the act of being erected, a rope gave way and it fell and broke into six pieces. On this disaster being communicated to Mr. Stamp, he promised, on his return to Columbia, to replace the loss with a spar of at least equal size and beauty; and in April of this year another was deposited by the same gentleman, free of all charges, in the Royal Gardens. It is of the same kind of Pine, but 41 feet longer—namely, 159 feet—and its diameter is 22 inches at the base, tapering regularly to 8 inches at the summit. There are two hundred and fifty concentric rings, or layers of wood, indicating as many years of growth; its weight is three tons, and it contains 157 square feet of timber. To rig and elevate his noble object the aid of the Admiralty was sought, and it

was immediately granted by the noble Duke who is at the head of that department of Government. His Grace gave instructions to Mr. John Isaac, the head mastmaker at Woolwich, and a sufficient complement of sailors and riggers, and the difficult task has been accomplished without the smallest accident. Many persons came to witness the interesting operation of raising so lofty a pole. The site is on ground about 15 feet above the level of the park, and at a suitable distance from the new "winter garden" now in course of construction. A cut was made through the side of the hill to its centre, into which the butt end of the spar was placed horizontally, and then, by means of a skilful arrangement of ropes, some being attached to sheers and others to several adjacent trees, this prodigious spar was hoisted in a few hours to a perfectly upright position, when it was found to be so absolutely straight that a plumb-line cut precisely through the centre of the butt end and the eap at the top. Flag-halliards and cross-trees had already been fitted; and a star, with reflecting facets and points, was affixed to the vane-staff. Being equal in height to the well-known Pagoda at Kew, this flagstaff may be seen, far and wide, and, if less conspicuous, it is far more graceful. The main object in erecting this noble spar is to illustrate the size, unrivalled beauty, and utility for naval purposes of the tree which produces it. The Douglas Pine abounds in all parts of British Columbia, including Vancouver Island, and has been known for many years in our parks and museums. A small-growing tree may be seen close to the entrance of the Royal Gardens at some distance, however, from the flagstaff, which is in the arboretum or pleasure ground. The latter, as is generally known, is open to the public from the 1st of May to the 31st of October, and the Botanic Gardens, with which it communicates, continue open through the year, Christmas-day alone excepted.—(*Times*.)

INSECT RAVAGERS OF THE ROSE.—No. 2.

(Continued from page 81.)

WE now come to the consideration of the insects which have been noticed injuring the flower of the Rose.

BALANINUS BRASSICÆ.—The petals of the Rose are often to be observed pierced by many very small holes. These are the work of the very minute Weevil, of which we annex a drawing magnified, as well as of the life size. It is of the same genus as the Nut Weevil (*B. nuceæ*), the larva or maggot of which feeds upon the kernel. This little Weevil with a palate more delicate feeds upon the Rose petals, although it more usually preys upon various parts of the Willow and garden pot herbs. It is no more than from one-seventh to one-sixth of an inch in length, including the long, slender proboscis, at the

Fig. 4.

end of which are its little mischievous jaws. Its colour is black, with a slight ashy down on the upper surface; the scutellum, or little triangular piece placed between the bases of the elytra or upper wings is white, and so are the breast and under side. The proboscis is slightly furrowed longitudinally at the base, and from it near the tip proceed the antennæ, the basal joint of which is pitchy red and the remainder blackish, and minutely haired. The prothorax or shield of the upper surface of the shoulders is thickly and minutely punctured. The elytra has rows of indented dots with minute ashy scales in a double row between the dots. The legs are black; the thighs clavate or club-shaped, with a small, pointed spine beneath. Sometimes the antennæ are entirely black, and in other specimens entirely red.—(*Westwood*.) They feed on the petals at night, and we know of no remedy but spreading a white cloth beneath each bush, shaking it, and crushing the marauders that fall upon it.

EUPROCTIS ATRIFLVA (*Yellow-tail Moth*).—This caterpillar feeds upon the petals of Roses, although more usually upon the leaves of the Oak, Elm, Pear, and Black Thorn. It is black, with two red lines running along the back, interrupted on the fourth or fifth segments by a small hunch or tubercle. On the

ninth or tenth segments the red lines form two wax-like spots. A row of spots formed of short tufts of white hairs passes along

Fig. 5.

each side of the caterpillar, and beneath these rows a longitudinal red stripe.

The Moth appears at the close of July, and is a very common species. It varies from $1\frac{1}{4}$ inch to $1\frac{3}{4}$ inch across the fore wings when these are expanded. These, as well as the body

Fig. 6.

and hind wings are pure white. The end of the body and the branches of the antennæ are yellow. The male differs from the female in having the under side of his fore wings brown, and a small dusky spot near the hind angle on the upper side; but this spot appears also slightly sometimes on the female, as is shown in the annexed engraving. The female also has a large tuft of yellow, wool-like hairs, which furnish a coating for the eggs as they are deposited.—(Westwood.) This is not the Yellow-tailed Moth described by Kollar.

MELIGETHES ÆNEUS (*Brassy Meligethes*).—The two preceding species feed on the petals of the flowers of the Rose when fully expanded. The little insects now before us (fig. 5, k, natural size, one represented flying; and highly magnified in the woodcut, fig. 7) frequents the Rose for the sake of its pollen, which we have observed it in the act of biting off with its small horny jaws, and devouring.

Fig. 7.

It measures a little more than one-twelfth of an inch in length, and has the upper surface of the body of a shining dark green colour, thickly covered with minute impressed dots, those on the elytra being rather larger than those of the head and thorax, the parts of the mouth are pitchy. The antennæ are black, the base slightly tinged with a pitchy hue, the prothorax and elytra have the

lateral margins slightly recurved. The legs are short and broad, the fore legs reddish, with the tibiae outwardly serrated, the four hind legs black. It is a very common species, and delights to fly in the hottest sunshine in the months of June and July amongst flowers.—(Westwood.)

VEGETABLE PRODUCTS OF THE HIMALAYAS.

(Continued from page 123.)

OUR next ground was up a lateral valley called Rhudagira, the stream from which joins the Ganges about two miles below the temple, on the left bank near Wilson's bridge. For about five miles the lower part on both sides was thickly wooded with Birch, some of the trees having had the bark stripped off to sell to the pilgrims by the villagers and the hill-men, who are engaged as porters by those who can afford that luxury in their pilgrimage. On some of the young trees the inner layers of bark are so fine as to resemble silk paper in texture, and in the higher hills it is very generally used as a substitute for writing-paper. Birch bark is one of the articles of hill produce exported into the plains, where, amongst other purposes, it is used in the manufacture of hookah snakes. On some trees there are upwards of twenty layers of bark, and when the trunk is free from knots it is taken off in one piece, which is sometimes 9 feet or 10 feet long and 3 feet wide, but in general the pieces do not average more than 3 feet by 1 foot or 2 feet. The inner bark of all adheres to the trunk, so that, though the outer is taken off completely round, the tree does not die, but for many years the bark is not renewed so as to be worth again taking off.

To about 11,000 feet or 12,000 feet, which is near the extreme limits of forest trees, the hills are everywhere well wooded, particularly on the northern and western slopes, which are almost everywhere clothed with forest of some kind. The opposite, the south and east, are more partially so, these sides of a hill being sometimes on the lower ranges nearly destitute of trees altogether. Commencing at the foot of the lower hills, we first find trees similar to those in the plains, and the forest here is only remarkable for the gigantic creepers. The common Pine then makes its appearance and is the principal tree, many hills in the lower ranges being clothed solely with it. The common Oak begins at about 4000 feet, and the Rhododendron the same. Between 7000 feet and 8000 feet the common Oak gives place to the Khuraoo, and at this elevation the trees of the colder European climates also appear: Chestnut, Sycamore, Box, Yew, Filbert, and others; besides the Rye and Morenda Pines, the pride of the Himalayan forests. The Cedar grows at almost all elevations; you find occasional groves as low as 3000 feet, but the great Cedar forests are not common at a lower elevation than 6000 feet. At 9000 feet Birch becomes prevalent, and a little higher, with the exception of dwarf Rhododendron, monopolises the forest. Above these come Juniper and a kind of Willow, with some other shrub-like bushes, till at 13,000 feet arboreous vegetation entirely ceases, and grasses, herbs, and mosses only are met with from thence to the snow.

The Cedar (*Cedrus deodara*) grows at almost any elevation and on any kind of ground; small groves or single trees being met with in the most widely different localities; in the low warm valleys and near the everlasting snow. Its favourite habitat is between 6000 feet and 9000 feet, and here only extensive forests of it are found. It seems to thrive best in a dry, rocky soil, and it is wonderful to see the places where some trees take root. In the perpendicular face of a smooth granite rock is a little crevice; into this a seed in some manner finds its way, vegetates, and becomes a large tree, flourishing perhaps for centuries where to appearance there is not a particle of soil, deriving sustenance probably from the rock itself. The Cedar grows to a great size, some having been measured with trunks upwards of 30 feet in circumference a yard from the ground. When in forest most shoot upwards in long, tapering, straight trunks, with rather short branches, and having the cone-like form of most Pines; but when scattered singly they often stretch out long massive arms, the ramifications of which being all horizontal, each with its foliage forms a surface almost as level as a table. The highest Cedars attain to a height of 100 feet. The wood is everywhere in the greatest esteem for building purposes, as it is easily worked, almost imperishable, and splits easily into planks—an indispensable requisite in a country where saws are unknown.*

* Since writing the above, I have found that the wood of the Cedar (*Cedrus deodara*) growing in the lower hills is much inferior to that near the snow, the latter being far more durable and of much finer grain.

The bridges over the Jhelum in Cashmere, which are constructed of this wood, are a fair criterion of its lasting qualities. Some portions are always under water, some only so half the year, and the rest always exposed to the atmosphere. These bridges have been standing for nearly a century, and are standing still, though so constructed that a few rotten timbers must of necessity cause the downfall of the whole. When subjected to the process by which tar is extracted from other Pines, Cedar wood yields a much thinner liquid, of a dark red colour, and very strong smell, known as Cedar oil. It is used by the Pularies as a remedy for the itch and other diseases of the skin, and all scrofulous diseases in cattle. The length of time this tree requires to arrive at even a tolerable size unfits it for introduction into other countries except as an ornament.—(*A Summer Ramble in the Himalayas.*)

(To be continued.)

TRADE LISTS RECEIVED.

Spring Supplement to Carter & Co.'s Gardeners' and Farmers' Vade Mecum.—Like a lady's postscript to her letter, this supplement is almost as bulky and as important as that to which it professes to be an addendum. It is of the same size as the Vade Mecum, and extends over fifty-six pages. It consists entirely of Bedding Plants, Fuchsias, Dahlias, Greenhouse, Stove, Herbaceous, and, in fact, all sorts of plants, and capital collections of them.

The Spring List of Soft-wooded, Bedding and other Plants, by E. G. Henderson & Son, Wellington Road, St. John's Wood.—An admirable catalogue, as all Messrs. Hendersons' are, and containing a fund of information about what are usually called soft-wooded plants. It contains some good woodcuts, among which are two good new things, *Epigynium leucobotrys* and *Convolvulus mauritanicus*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

STIR the surface of the soil where the late rains have hardened it. Prick out all sorts of advancing seedlings that they may get stocky and strong before their final planting. Above all things, look after the slugs, which are very numerous this season; sprinkle the crop that they are most likely to attack with fresh slaked lime and soot mixed, and lay traps for them—such as rhubarb or cabbage leaves, slate, pieces of board, &c., and turn them over daily, when numbers will be found on the sides next the ground, and can then be destroyed. The Broccoli season being now nearly over, the stumps should be all cleared away and the ground dug, or if intended for Celery-trenches these may be prepared without digging the whole of the ground. Keep all the salading crops well watered in dry weather, or they lose much of their crispness. *Beans*, as soon as the pods begin to form at the lower part of the stem top the plants, which will greatly forward the cropping of them. *Carrots*, sow Early Horn, to draw young during the summer. *Cauliflower*, the early crop to be liberally supplied with water; manure water to be given if very large heads are required. *Cucumbers*, peg them down as they advance in growth under the hand-glasses; water to be given, when they require it, in the morning, and then only when it is likely to be succeeded by a fine day. *Parsley*, sow seed, and thin out the plants of the early sowing to 6 inches apart. *Peas*, at the time of sowing during dry weather water the drills after they are drawn, and before the seed is sown. *Savoy*s, prick out some of the earliest sowing. Shade with mats, if bright weather, for a few days until the plants take fresh root-hold. *Scotch-kale*, the same as Savoy's. *Spinach*, thin out the early crops, and sow again for succession.

FLOWER GARDEN.

It is advisable to fork up the borders after heavy battering rains. The Pæonies, Phloxes, Delphiniums, and other tall herbaceous plants to be properly staked. Thin out annuals. Remove all decayed leaves and flower-stems. Plant out on rich soil a good supply of Stocks and Asters for the autumn, and sow a succession of annuals for filling up vacancies that may occur. With the wind due north, and a fair prospect of a sharp frost any time, there is no great encouragement to commence bedding out in good earnest. It is to be hoped, however, that we shall have experienced a favourable change before the appearance of

this notice, and that the planting of all properly prepared stock may be carried on under favourable auspices. To begin with Calceolarias, Verbenas, Scarlet Geraniums, and leaving Heliotropes, Ageratums, and such things that are more susceptible of injury from frost, to the end of the week. A few spruce fir or other evergreen branches stuck in amongst the plants after bedding would be of service in protecting them from the drying effects of bright sunshine, and from any slight frosts that may occur. Verbena and other straggling plants that are liable to injury by being blown about by the wind to be pegged down immediately after planting out, and a good watering to be given early in the morning to settle the soil about the roots.

FRUIT GARDEN.

Continue to nail in the young shoots of all kinds of fruit trees as they become sufficiently advanced, and keep the finger and thumb at work amongst superfluous ones. Give the Strawberry-beds a slight forking over, and have some available material at hand for laying about them when the fruit is swelling, to prevent it getting splashed with dirt: straight wheat straw is often used, as are also spent hops. Remove some of the watery shoots from Gooseberry and Currant bushes.

STOVE.

Pay attention to the various young stock intended for blooming through the autumn and winter. The *Euphorbia jacquiniæ-flora* looks gay if planted three in a pot. The *Gesnera elongata*, the *Begonias*, some of the *Justicias*, and the *Geissomerias*, &c., are worthy of careful culture for the same purpose. The plants that are now growing freely will require attention in stopping, training, &c.; give them plenty of pot room, and all the sunshine that they will bear without scorching. The creepers to be looked over frequently to prevent their growth getting into confusion. Syringe, and shut up early in the afternoons of bright days, and be as sparing as possible in the use of artificial heat.

GREENHOUSE AND CONSERVATORY.

The Indian Azaleas that have been some time growing to be kept in heat until they have set their buds, when they may be removed to the open air to ripen the wood. Look well to the plants for summer and autumn decoration, and do not allow them to sustain a check for want of pot room or carelessness in watering. As the New Holland plants go out of bloom pick off the seed-pods, and cut the shoots back to form a compact plant; to be placed in an airy part of the greenhouse, and when the buds have fairly started, to be shifted, if they require it, into a larger pot, and then kept close for a fortnight to encourage a free root action. Shade *Pelargoniums* in flower, and shift and stop such as are wanted to flower late. Watch closely for insects, especially green fly and red spider, and act against them directly they are detected.

W. KEANE.

DOINGS OF THE LAST WEEK.

THE weather continuing dry, sowed more Beet and Early Horn Carrot for succession, Lettuces, Cauliflower, Peas, and Beans for ditto. Gave the final earthing up and spreading out to Cauliflowers that had been wintered under glasses, and now forward and coming in. Sowed Spinach, Turnips, and Radishes for succession; replanted and propagated hardy herbs; watered with soot water, about 70° in temperature, the earliest out-door Peas. Potted off, five in a twelve-inch pot, Dwarf Kidney Beans sown in boxes, to be grown under protection; also, potted a quantity, three in a four-inch pot, to be transplanted afterwards and be protected a little at first; those sown out of doors owing to the dryness not yet vegetating. Sowed also Scarlet Runners, and planted some thick in a reserve-bed to make use of filling vacancies, or to serve for additional rows. Cleaned and gathered from Kidney Beans under glass, and gave them plenty of manure watering, which is making old plants bear as well as new ones would. Pruned and thinned shoots in Cucumber-beds, and cut fruit before getting too large or old, the object being to have fruit crisp-eating, and not hard policeman's staves. Used the Dutch hoe freely among all growing crops—as Spinach, Asparagus, Seakale, Artichokes, and more especially among young Onions, Parsnips, Carrots, &c. Here the old proverb "A stitch in time saves nine," is well proved. A man will go over a great piece of ground when the seed weeds in myriads can just be seen by looking carefully along the ground; but it is a different matter when they get 3 inches or 4 inches high, or even higher than

that. Then the cleaning is, indeed, a disheartening work, and tells of false economy or bad management either in master or servant. The surface stirring is also of benefit in preventing the ground cracking, and lets the rain when it comes percolate nicely through the soil, instead of running off or bolting down the cracks. Thanks to the timely watering we shall have a good crop of Cabbages after all, though the quarter will not be so even as usual, which will have one advantage that the crop will come in more in succession, than even if the quarter looked better. Planted out Cauliflower and Cabbage, spring-raised under glass, for succession, and pricked out under hand-glasses in a border a few Cauliflowers from the open-ground sowing, to bring them a little earlier.

Ran the Dutch hoe through the rows and beds of Strawberries to settle all the seed weeds, and strewed a little powdery quicklime among them, expecting rain to come soon to wash its caustic qualities into the rich surface soil, and give many a worm and slug their quietus. So that at gathering time when the fruit is covered with nets we shall not be annoyed with seeing the best fruit crawled over, bitten, or hid with weeds, when it would hardly be safe to send active boys to pull them out without a trustworthy captain over them, to see they kept "whistling" all the time. Watered trees fresh planted, and syringed them twice a-day in the dry, sunny, cold weather, that kept drawing their juices from every pore. Removed evergreen branches from part of Gooseberries that seem now large enough to be safe. Currants as yet seem safe owing to the evergreen branches, but many places are but shades of what they were. Syringed with sulphur and soot water Peaches and other trees a little troubled with insects. Tried Gishurst for the first time on a few trees in pots, using it very weak, as much as a walnut to four gallons of water, and found that the insects did not at all relish it, whilst the plants were not at all injured. When people will put half a pound of soap, half a pound of sulphur, and half a pound of tobacco, all well boiled together into five gallons of water, and then speak confidently of its efficacy in destroying insects, I verily believe them, but should have no great desire to possess the tender plants from which the insects were removed. It is preferable to use weaker doses even if they should be repeated. I should consider an ounce of each for such purposes more than sufficient. Stopped and fertilised Melons, watered Strawberries in houses, adding a few more as room could be had, as when once used steadily to them employers do not like any stop or gap between the earliest ones in houses, and the earliest out of doors. Watered Vines in pits now swelling freely; watered Figs to prevent dropping; Peaches to assist swelling. Picked out a few small berries, and large ones too where too thick, in the earliest Vines, few laterals now appearing, all the strength going into the fruit; but what few appear allowed to remain to increase root action. Thinned evening and morning in the second house, and during the rains of Saturday all day, and tied out the late-house now showing bunches, removing redundant shoots, average temperature of late house from 50° to 55°, but will gradually raise it to 60° and 65°.

In the pleasure ground having some time ago mowed the lawn near the house, and a good swarth all round the sides of the walk, to prevent daisies or other beauties, but not desirable on walks, shedding their seed on the gravel. Owing to the dry weather let the mowing chiefly alone, and kept turning and breaking the soil in borders and flower-beds, and getting them all nicely edged ready for planting time, though they will, probably, get a turning a time or two before then. Lined out all the sides of the gravel walks that there should be no curves out and curves in to offend the eye in walking along them during the summer. Nothing is more distasteful to me than a deep raw earth-edge to a gravel walk. The earth a week or two after the lining should not be seen, and will not be if the turf is not more than from 1 inch to 2 inches above the gravel. This lining out with the line and cutting with the edging-iron, I consider indispensable every spring, as then the garden shears can manage all the edgings of the walks nicely all the summer afterwards; and the picking up the cut grass, and switching with a soft, moist broom, is more easily done when there is a firm, straight edge to fall back upon even though that edge be not seen unless you look for it. What may have to be removed, as little as possible, from the outside of the cutting-iron, is either moved with a draw-hoe first, or more generally taken up with a sharp spade, holding it obliquely to the edging and placed at once in a barrow, for we allow no heaps to be made to waste time in cleaning up their bottoms. Any weeds on the walk are picked up at the same

time, all black and greasy places where rain or snow had lodged, or where trees had shaded, is scraped with a draw-hoe as thinly as possible, so as to leave all clean, and thrown at once into the barrow, and then the walks are hard brushed with a rough broom, and when opportunity offers a sprinkling of fine gravel is thrown along each side where fresh cut, and a rolling given, which insures better walks with less trouble than digging and trenching them every year. I should have premised that the grass sides of the walks are well rolled before cutting, and as rolling the walks has a tendency to raise the grass at the sides by abutting against them, in rolling the grass the roller is allowed to hang 2 inches or 3 inches towards the gravel, which thus tends to keep the grass at the sides level and also firm to the edging-tool. And what comes of all these parings and sweepings? Thrown away, of course. Oh, no. This season there is a much larger heap of dead rose and shrub tops, prunings, &c., than usual at this time; these will be covered with these turf edgings, sweepings, vegetable stems, old used earth, and fire being set to the whole, we shall in ten days have a good heap of charred rubbish and burned earth in a nice warm state, just in prime order to mix with a little leaf mould and permit of a small handful of such mixture being given to bedding plants when turned out, so as to give them a good start at first.

These bedding plants are now the very *botheration*. Never did gardeners make such a scourge for lashing themselves withal. Go where you will you find that they must be had, and that, too, most generally entirely as articles of superfluity, without any separate means being set apart for them. Room, therefore, is ever and anon the cry, and to find room many begin to turn out in such haste as to have reason to repent at leisure. It is best to harden well off by degrees, and many things such as *Calceolarias* now require little protection; but the very fact of a sheltered place and standing thick together enables them to stand more cold than they would do when turned out singly in a bed or border a foot or more apart, and as yet unacquainted with their new habitat. A bed of *Calceolarias* thickly planted stood well on Thursday and Friday, the 9th and 10th, when we had from 3° to 5° of frost, with a few spruce branches stuck among them. Pricked out *Perillas* in celery-beds, and turned out many other things as *Lobelias* and *Geraniums*, protecting with an old sash or a mat, and exposing fully during the day. Potted Castor Oil plants and *Daturas*, and gave them a little heat. Sowed Balsams, moved *Brachycome*, *Chrysanthemum Burridgeanum*, *Lobelia speciosa*, *Convolvulus*, *Tropæolum*, &c., out of slight heat into slight protection, but kept a sharp look out lest such a Christmas air as the evening of the 10th did not interfere with them.

Syringed *Azaleas* and kept them close that had done flowering, hybrid tree *Rhododendrons* ditto. Moved *Fuchsias* to conservatory, kept *Cinerarias* and *Calceolarias* cool and moist. Gave plenty of air to *Pelargoniums* to insure the foliage being dry before the sun shone much on them. Gave manure water to those knotting for bloom. Shifted succession plants, gave larger pots to different kinds of *Scarlets* and pink *Geraniums*, &c., intended to bloom in-doors in autumn. Selected younger plants for potting to succeed them, and will do the same with the variegated kinds ere long. Shifted, also, *Fuchsias*, *Begonias*, and many soft-wooded plants requiring heat, and took care as much as possible to make sun heat serve the purpose needed by early shutting up, instead of burning coke or fuel when the sun could manage most of the work. Saturday, the 11th, the rain came in torrents, and potting, cutting tallies, making bushy branchy stakes for flower-beds out of larch and spruce prunings, were the order of the day. In exposed windy places these twiggy bits of branches are far better for flower-beds than any amount of straight sticks, the twigs holding the plants firm.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

MELON PLANTS DAMPING OFF (*M.*).—It is very likely there is some parasitical fungus in the soil. If you do not grow in a pot remove the soil from the part and add fresh. But, after all, these maladies will happen do what we will.

INSECT ON ORCHARD-HOUSE TREES (J. F.).—It is the American Blight *Aphis lanigera*, and probably came to you on the trees. Remove them from the house, or the insects will migrate to others unattacked. Scrub the spots where the woolly matter appears with spirit of turpentine, but do not let it touch the leaves. The trees should not be returned to the orchard-house until all appearance of the insects is removed.

GRAPE VINE LEAVES DECAYING (G. F. D.).—These and the young bunches shanking, as well as the vigorous shoots gangrening, are evidence that the roots do not supply sap sufficiently fast to sustain the rapid growth now going on. Syringe less and only at night; give air freely by night as well as by day. The roots being outside are too cold, much over the roots at night, but uncover during sunny days. The Camellia leaves are stained brown like others we have seen where the roots have been sometimes too dry, and at other times too wet, whilst the leaves were constantly exposed to bright sunshine. The roots have been injured by that or some other accident.

DISEASED LEAVES AND FRUIT OF PEACHES (Four Years' Subscriber).—Fumigation will have no effect on such Peaches. They are suffering from canker, and from not having enough of sun to ripen the young wood the previous season. Under such circumstances the less syringing you give them the better. The fruit is approaching the stoning period, and the diseased and imperfect juices are unable to supply them with necessary nourishment. We can hold out no great hope even for next year, if the Peach trees continue much shaded during the summer. If put in a house by themselves we would prefer shading a little in very hot days instead of syringing them much, when the leaves fall off so easily. The Pelargoniums will do better in the cool house than in the hotter and more shady one. Most likely they would do better in a pit, or on a stand with a protection of calico or muslin over them or around them if there is no greenhouse. The Figs will ripen under the circumstances, but they will be deficient in flavour, and every year afterwards, with such shade from Vines, there will be less and less of fruit, owing to the leaves not getting enough of sun, and the soft state of the young wood. They will do best in the house with most light, but you must give no very sudden change of temperature, or it may cause the fruit to drop; it there is only from 3° to 5°, or so, it will not hurt them. The leaves of your Begonia are chiefly injured by your syringing and the sun shining upon them when wet. Avoid the syringing, and if you can raise the temperature to 60°, the fresh leaves will come nice and well coloured. Even under the best culture some of the lower leaves will begin to be a little blotched when very old, for all evergreen plants are so far deciduous; but your case gives unmistakable signs of the sun striking on a moist surface, and under a low temperature. These plants will do better under the shade of your Vines, and where the leaves shall have no moisture except what they condense from the atmosphere in which they grow. Your Gishurst Compound could do them no good whatever, but at 2 ozs. to the gallon might do them much harm. We detect not the slightest appearance of insect or mildew, and we have no faith in any medicine that will cure all diseases, all ills, and all mismanagement.

MELON (H. Helyer).—We do not know and cannot hear of such a variety as the *Muscatoello*. The writer in "All the Year Round" may be right in saying it is a red-fleshed Persian "superior to anything of the kind in juiciness and perfume," but we do not think it has been cultivated in England.

HEATING A GREENHOUSE—CUCUMBER CULTURE (A Notice who Wishes to Excel).—We do not think there is much the matter. We would have preferred the flue to run along the front of the greenhouse as well; but that would interfere with the heat in the forcing-house, if you grew Cucumbers early. We hardly think that at the distance from the flue which the slates will be, there will be great danger of burning the roots; but it would be as well to have 3 inches or 4 inches of open rubble, cinder ashes, gravel, &c., over the slates, and then with a small round drain tile or tube of any sort from 1 inch to 2 inches in diameter, one end resting on the rubble and the other above the bed, you could not only supply moisture beneath the plants, but by means of plugs in your tubes admit heated vapour into the atmosphere of your house at will. We allude to this because you do not mention any mode of giving atmospheric moisture except by a copper over the furnace at one end. If your flue is only open under the pathway, we think you will hardly have enough of direct atmospheric heat, and as you have a chamber we would have a sliding board a foot long and 9 inches wide in the centre of each side to let out the heated air when necessary. That, also, could be moistened by pouring water in the chamber, but not on the flue, or by evaporating-basins, or tiles on the flue. The heat you can prevent going up the chimney by having a damper close to the end of the flue in the chimney, but you must never have it quite shut. The back pit when not wanted for cuttings or low-growing stove plants might also be used for Cucumbers. We presume you train on a trellis, the best mode for such a place, and then the front pit will grow plants enough to cover all the roof. You must just risk the consequence if you grow Kidney Beans or anything else. If you just syringe and kept healthy there is little more danger than from other plants, but the more plants you put in your house as main crops, the less will you excel in individual things. You might have filled your chamber with loose bricks and stones, and concreted the surface, and thus saved yourself all the bother with supports and slates; but as the slates are there it would be a pity to make any alteration. All the varieties of the true Lion House Cucumber are short: 12 inches are a good size. Crosses with it, and smooth-skinned like it—such as Telegraph and Cox's Volunteer are long—say from 16 inches to 24 inches. The pointlessness may be owing to dryness at the slates and want of vigour, and the one can be remedied by making holes and watering, so as to be sure of reaching the bottom, and the other by manure waterings and rich surface dressings, as rotten leaf mould. Under your circumstances we think it would be waste to turn your copper into a boiler with hot-water pipes. If you had merely taken a short flue through the forcing-house, and built a brick stove in the house, with a small boiler as that used by Mr. Rivera, and lately described and figured by Mr. Fish, you might have heated both houses more satisfactorily; but there is nothing to prevent you doing so with the flue. For such forcing as Cucumbers, however, we would have preferred half of the flue next the fire, at least, being of brick on bed, instead of brick on edge. See what has been lately said and still to be said on Cucumber culture.

ROGG'S FRUIT MANUAL (A. B.).—There will not be a second edition for some time. It is impossible to say when. Your warning about sending fowls to London has given rise to a communication in our "Poultry Chronicle."

SMALL GREENHOUSE (Flora—, Kingsdown).—We have given all such information as you wish as to keeping plants even to repletion; but we would be glad to oblige you if you give us more data as to the space you can appropriate for such a purpose, and the attendings of the spot as to walls, &c. In our "Greenhouses for the Many" are full directions. You would see also in a late Number, page 99, how a correspondent built a small house and put his stovehole inside, but then that house would take up half your space of ground. Is there any means of putting a little pit close to the house, so that you might borrow a little heat from the kitchen fireplace? Where enjoying the house is the object, you ought to have a place that you can walk in, and be able to examine and do everything for your plants under cover. For such a small garden a well-lighted spare room would hold a great many plants; and with a fireplace in it, and a damper or register grate, shutting down the register at night within a quarter of an inch or so, a great many plants could be kept more safely, and with less trouble than in a pit. We last season advised a correspondent to turn a lumber, merely slated, garret into a greenhouse, by placing strong tiles of glass instead of slates on the roof, and using a small iron stove in the centre of the place in cold weather in winter. Before the winter comes we will do what we can for you when you give us more details, for after all we can only help those that are resolved to help themselves. When you write again do not leave anything out as if we should be able to recollect what you now tell us. You need not despair as yet as to the annuals, though in such a cold spring most of them would have done as well if not sown until the middle of April. We did not sow one until the end of the month. Your *Gilia* or *Collinsia* we presume have come. There are few *Daturas* that will come well this early. They should be kept in a frame until they are up. You may pot off singly your *Dianthus lacinatus* in small three-inch pots, using sandy loam and leaf-mould; and by the time the pots are filled with roots you may either turn them out in a row or in a small bed from 12 inches to 15 inches apart in similar well-aired soil, or you may transfer them to six-inch pots and bloom them in a window or balcony. If your annuals were sown in rows or in beds, in case there should be any breaks, if you have any seed left you might sow thickly in a bed in a warm place, and protect at night with a mat or a piece of calico. These could be lifted in little patches and used to fill up openings. See "Doings of the Week" for the new series.

VEGETABLE MATTER FOR PAPER MAKING (S. W.).—We submitted the Conferva to a papermaker, and this is his reply:—"This matter has no strength, consequently is useless for making paper. You will find if it is well shaken it will go entirely to dust."

STRAWBERRY PLANTS IN POTS NOT BLOOMING (M. A.).—The repotting should have been done directly, and so as not to disturb the balls. The accident however, though it might have interfered a little with the fruiting, would not have prevented the flower-buds showing if they had been there. We think you either encouraged the plants to grow too long in the autumn so that no flower-buds were formed, or they were so weakly as to be injured by the severe frost. We would plant them out, and most likely you will get a great crop next season even if they showed a few in the autumn. We have forced Admiral Dundas but little, but it would do for an orchard-house though we should not like it for early forcing. The *Carolina superba* we have never tried in pots.

ASPECT FOR GREENHOUSE—HEATING A PIT (J. Danvers).—See answer to "A NOVICE WHO WISHES TO EXCEL." If confined to a flue you had better have that go round two sides and one end of the house, a pit in the middle of 3 feet, and a bed on each side above the flue, with a chamber beneath: or the space filled with hollow stones and finer at the top to receive the pits for cuttings, &c. In either case it would be well to have openings for top heat. For Azalea forcing the flues would be sufficient without beds.

GRAPES AND VINE SHOOTS SHANKED (M. A. M.).—The reply we have given to others to-day applies to your case. The above-ground parts are made to grow faster than the roots can supply sap for their development.

POTTING—HEATING BY GAS (Nil Desperandum).—There is no such seeming mystery in potting. As a general rule, whatever the composition of the compost, fine, or rough and open, plants will grow most freely when not very hard potted; but they will bloom and fruit best when the soil is squeezed together as firmly as possible. When the sun causes the earth to shrink from the sides of the pot, stir the soil there to fill up the cracks, squeeze it down and add a little more at the sides, that the water may be thrown more to the centre. In extreme cases of dryness at the centre, and when the pots are large, set them overhead in a tub of water until no air bubbles come and a few minutes more; that will insure all the roots and soil being thoroughly wetted. For full directions on the e-matters, procure our "Window Gardening for the Many," price 9d. We are in possession of no such tables as to the comparative cost of heating small places by gas or stove. We would publish memoranda on the subject if given, though we do not attach much importance to them. We have not had great experience with gas ourselves, but knowing how easily it can be applied in many circumstances in towns, two friends obtained for us memoranda on the subject which we mislaid and never used, for the results were as wide as the poles asunder. On a little bantering cross-examination, it turned out that though both had used gas, and a small iron stove, the one made the stove beat the gas to nothing, and the other made the gas thoroughly victorious over the stove! We should be glad to receive broad data on this or any other subject as to heating, but after much practice and experience we have come to the conclusion that there is more in the manner of using the means than in the means used. One man will do wonders with an upright tubular boiler, a second is all for retorts, a third for cannons, a fourth for conicals, a fifth, sixth, and on to the dozen with the old saddle-back.

MUSCAT GRAPES SPOTTED (Titus).—This is always a symptom that the above-ground parts of the Vine are growing faster than the roots supply the sap required by such rapid development. Give more air and less moisture in the house, and keep the roots warmer and well supplied with tepid water. It may be that the roots have descended too deep, but of this we can give no opinion, but only draw your attention to the subject.

BEETLES ON POT VINES.—I was at Hatfield House the other day, and in a house of pot Vines I noticed a bunch of wadding tied round the stems. This was to prevent so far the ravages of a beetle, in stripping and boring the leaves. I enclose two.—R. F.

[The beetles sent are the destructive weevils, *Otiorhynchus vastator*. They must be sought for after dusk with a light. The wadding would be of no service except at the spot which was covered by it, unless it were daubed over with birdlime.—W.]

FRENCH-BORDER (F. A. C.).—The Verbena will be too high in front of the blue Lobelia, and you may reverse them. The styles of growth of the Verbena and Saponaria must then be the contrast. The rest are right, but Mr. Beaton says he never sent out a white Nosegay, and that the only white Geranium he raised that was good for anything, is the one called *Hendersonii*, and that there is no other white Geranium that is yet proved to be fit for flower-beds. Eight inches is a fair size for a white band of variegated Alyssum, 10 inches for the blue Lobelia, 14 inches for the scarlet Verbena, 18 inches for the Saponaria, 1 foot or 14 inches for the Calceolaria, from 1 foot to 18 inches for Tom Thumb according to the size of the plants, and 18 inches for the Heliotrope. But on a wide border these measures might each be doubled, and the arrangement would look better; there would then be double lines and double the number of plants even at the smallest spaces as above. The Lobelias and Saponaria seedlings should be in two rows to get the spaces filled up all the quicker. There should be no empty ground between ribbon-rows after the plants grow freely, and no one plant must be allowed to run into the next row as most Verbenas will do unless they are constantly looked after and trained within their boundary. Give any white Geranium 15 inches room only.

VARIOUS (An Old Subscriber).—Horseradish culture is given at page 42 of our No. 3. None of the birds or animals you mention will hybridise together under ordinary circumstances.

NAMES OF PLANTS (S. Devon).—No. 1. *Anthriscus sylvestris*. No. 2. *Euphorbia amygdaloides*. (*Harrie*).—*Smilacina bifolia*, called also *ma'aa*. *Thunberg*. (*A. B. Cole*).—Your plant is *Linaria cymbalaria*, or Ivy-leaved Snapdragon. You can be admitted a Fellow of the Royal Horticultural Society. The lowest annual payment is two guineas. If you write to "The Secretary, Royal Horticultural Society's Office, Kensington Gore," at once, you may be elected before the end of the month.

FLOWER SHOWS FOR 1861.

JUNE 5th and 6th. ROYAL HORTICULTURAL SOCIETY. (Plants and Fruit.) *Garden Superintendent*, G. Eyles.

JUNE 12th and 13th. YORK. *Sec.*, J. Wilson.

JUNE 19th and 20th. BRIGHTON AND SUSSEX FLORICULTURAL AND HORTICULTURAL SOCIETY. *Sec.*, E. Carpenter.

JUNE 25th. ROMFORD. (Plants, Flowers, and Fruit.) *Sec.*, Mr. George Griggs, Romford.

JULY 6th. CRYSTAL PALACE. (Rose Show.) *Sec.*, W. Houghton.

JULY 10th. ROYAL HORTICULTURAL SOCIETY. (Rose Show.) *Garden Superintendent*, G. Eyles.

SEPTEMBER 4th and 5th. CRYSTAL PALACE. (Dahlias, Cut Flowers of other descriptions, and Fruit.) *Sec.*, W. Houghton.

SEPTEMBER 11th. ROYAL HORTICULTURAL SOCIETY. (Dahlias and other Cut Flowers.) *Garden Superintendent*, G. Eyles.

SEPTEMBER 18th and 19th. BRIGHTON AND SUSSEX. *Sec.*, E. CARPENTER.

NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums.) *Garden Superintendent*, G. Eyles.

NOVEMBER 12th and 13th. STOKE NEWINGTON CHRYSANTHEMUM SOCIETY. *Sec.*, W. T. Howe.

NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show.) *Sec.*, W. Houghton.

N.B.—Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

MAY 21st, 22nd, and 23rd. CHESTERFIELD AND SCARSDALE. *Hon. Sec.*, Mr. Thos. P. Wood, jun., Boythorpe House, near Chesterfield. Entries close May 1st.

MAY 22nd and 23rd. BEVERLEY. *Hon. Sec.*, H. Adams. Entries close May 4th.

JUNE 4th, 5th, and 6th. BATH AND WEST OF ENGLAND. *Steward*, S. Pitman, Esq. Entries close May 4th.

JUNE 19th. THORNE. *Sec.*, Mr. Joseph Richardson. Entries close June 12th.

JUNE 19th, 20th, and 21st. COALBROOKDALE. *Secs.*, J. B. Chuae, and Henry Boycroft, Coalbrookdale.

JUNE 28th. DRIFFIELD. *Sec.*, Mr. R. Davison. Entries close June 22nd.

JUNE 28th and 29th. TAUNTON. *Sec.*, Mr. Charles Ballance. Entries close June 14th.

JULY 3rd, 4th, and 5th. BLACKPOOL AND WEST LANCASHIRE. *Sec.*, Mr. E. Fowler, jun., Market Street, Blackpool. Entries close June 30th.

AUGUST 26th, 27th, 28th, and 29th. CRYSTAL PALACE SUMMER SHOW. *Sec.*, W. Houghton.

SEPTEMBER 3rd. POCKLINGTON (Yorkshire). *Sec.*, Mr. Thomas Grant. Entries close August 26th.

SEPTEMBER 24th. BRIDGORTH. *Sec.*, R. Taylor, Bridgorth.

DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. *Sec.*, Mr. J. B. Lythall, 14, Temple Street. Entries close November 1st.

DECEMBER 11th, 12th, 13th, and 14th. CRYSTAL PALACE WINTER SHOW. *Sec.*, W. Houghton.

SENDING POULTRY TO THE LONDON MARKET.

WE did not enter upon the *vezata questio* of sending poultry to market till we had well weighed all the objections and difficulties. Their name is Legion. We encounter them every year at this season, after we have been trying to induce people to supply the need of London from the abundance of their yards; but we fancy we are very guarded. Two years since we explained the vocation and style of business of the "higler," and we then said, speaking of the London market, that they were essential to its

supply; and endeavouring to meet any objection that might be raised, we said, "wherever there are good fowls to be had, there will be found buyers for them, and as soon as there is a supply, there will be a demand." We have since said, that those who have but a few fowls every year cannot expect to be as successful, or to make as good prices, as those who live entirely by collecting and fattening fowls, and supplying the London market with them. Fancying few have ever had more, or as much to do, with poultry in every shape as ourselves, and knowing that it may be made more than an inexpensive pursuit, we "harp upon it" every year. We have always sought to render any disappointment impossible. To use Cobbett's words, "We have not only tried to make ourselves understood, but we have tried to make it impossible you should misunderstand us."

Markets for provisions are not as well understood in England, nor are they as much frequented as in France. With the exception of ladies who may go to buy a few flowers, or perhaps an idle man who may like to buy a piece of fish, markets are used only by those who trade in the wares that are exposed, and the reason is plain: they are the best judges of the article, and when a man becomes known as a buyer, he will find a middle man to be the most advantageous salesman to him. A market is for the convenience and benefit of the seller. There is fluctuation in everything, and however unimportant a week may be to a pig of iron or a bale of cotton, it is all essential to a side of beef or a hamper of fowls. The buyers in a market comprise all who deal in the article. Some buy only the best, others are content with mediocrity, while the last class buys anything and clears up every lot. These again come from different parts, and by these means they form the certain demand there is for every quality in a market. Where producer and consumer form "a league and covenant" to extinguish, discourage, and do away with the iniquitous middle men (like a family we knew where the members determined to eschew alum, potatoes, and baker's iniquities, and to have home-made bread; and where we used to see the funniest flat loaves, so close inside, that we thought, till we were corrected, they were American dampers. We were told the bread wouldn't rise, and when one day it was necessary to go out and buy a loaf, the children asked why they did not always have CAKE), one contracts to supply, the other to consume.

Now, let us suppose such an arrangement. The steward of a club, the manager of an hotel, or the head of a large family, undertakes to receive weekly or daily a supply of fowls from an amateur—eight, ten, twelve, or twenty couples per week. The producer is ready, and, let it be remembered, when fowls are fat, they *must* be killed, there is no such thing as keeping them in perfection. Well, there comes a note from the steward of the club, there is a threatened dissolution, all the members are off to the country; the manager of the hotel writes the house is empty; there is a death in the large family, there will be no company for some time, and, therefore, no demand for poultry. Or about the end of March producer having five or six weeks' consumption of winter fowls in process of preparation, is informed he must send no more of them, all the demand being for spring chickens—things he will not have for six weeks. On the other hand, imagine a royal marriage, christening, or some national fête, the opening of the Universal Exhibition, or some such thing. Purveyor receives notice, the demand is doubled, and he is obliged either to confess his inability to supply it, or he has recourse to the nearest market to eke out his supply. This is where we want to come—all these markets are feeders to the great market in London. From one person there is neither certainty of supply or demand, nor, were it required, can there be uniform quality. A market affords supply to one, it is an outlet to another. For instance, suppose a contract between parties such as we have described: the consumer is not to receive discoloured, broken, black, or yellow-legged fowls, nor must they exceed a certain size. There may be many such in a lot: they must go to market, and they will there find purchasers. It is supposed, and it is generally true, that those who regularly attend a market are thoroughly and practically acquainted with its usual contents. They not only know the buyers of the different qualities, but they know how to select and arrange the necessary lots. The higler attends the market, or goes his round, and, having made his purchases, he then sorts or lots his fowls according to their merits. Of forty-eight he makes four dozens, all differing not only in quality, but also in the price they will make, as much, probably, as thirty or forty per cent. between the first and last lots. He has bought twelve chickens of A. B. It is more than likely that they,

although of the same age and treated alike, will contribute to each of the dozens. In a local market the best alone would not realise their London value, private consumption will not clear all up, but sorted and properly arranged all will be sold in London.

The higgler not only has his knowledge of their quality, but he is also well acquainted with the form and times in which they are most saleable. It is his interest, almost his livelihood, to study these things, and they have their influence in enabling him to give more than those who lack his knowledge.

As we are not disposed to retract one word that we have written, we will sum up and leave the verdict for our jury. We have a feeling of impunity in doing so, as the law requires unanimity, and our jury is composed of thousands of readers. Our advice always has been to amateurs to feed and breed for the London market, but we also wish them to supply by means of the bigglers.

It is with selling poultry as with almost everything else, there is a beaten track, and money can be made only by following. "What can the king do that has not been done before?" There was a time when these complaints came from Lincolnshire, Wiltshire around Salisbury, Berkshire, the northern parts of Hampshire, and Essex. They have ceased, and all these places are now supplied with bigglers. Ask, Reigate, Horsham, Westerham, Croydon, Wokingham, Salisbury, and a hundred other places. Ask Boston, Louth, Spalding, and Bury St. Edmunds, what have been the prices of young poultry during the last three months, all given by bigglers, whether the regular demand has not created a regular supply satisfactory to all parties, and, consequently, a just one. An injured party is never satisfied.

Geese will never find the same certain market as fowls, if produced early. The expensive, and, consequently, profitable fowls are all eaten by the aristocracy, but Geese are not fashionable with them. The consumption of Geese in the spring as green Geese, and at Michaelmas as a national dinner, has diminished to less than a tenth of what it was, whilst in revenge the numbers eaten at Christmas would not be credited.

NAMING THE BREEDERS OF EXHIBITED FOWLS.

I SHOULD like, through your columns, if you think the suggestion worthy of a place in them, to propose to the managers of poultry shows, and especially to those of the leading ones, that exhibitors, besides describing the breed, age, &c., of their specimens, should also be requested to state, if possible, the breeder of them. It is done in the case of all other stock at agricultural meetings. It would, I think, encourage the sale of birds, as breeders would then retain considerable interest in the success of their birds even after they had passed into other hands; and it would afford reliable information as to where the truest and purest blood is obtainable.

If the Birmingham Council and the indefatigable Secretary of the Crystal Palace Show would introduce this new feature into their entry certificates I think it would add to the interests of the shows, and be of benefit to amateurs.—G. H.

PROFITABLE POULTRY KEEPING.—No. 5.

(Continued from page 106.)

To those who may feel inclined to try their hand at poultry keeping I would say, "Take care of your old birds." By these I do not mean hens of some three or four years, but those which may be falling off in productiveness, or that may have been disabled by accident but not vitally injured; for from these will be obtained the larger profits of their undertaking.

Put such at once up to feed, placing them in pens, or in any confined corners where they can be kept warm and dry, and feed liberally; and if the "cramping system" be resorted to, they will be fit to send to market as capon. A fowl of some eighteen or twenty months old, healthy, but worth little to sell—say 1s. 6d., may, by extra feeding and good management, quickly be made worth 5s. or 6s.

It is unnecessary to advert to the description of bird held to make the best capon; but, whichever it may be, breed and manage as now stated.

Beat equal portions of wheat and barley meal, and occasionally Indian corn meal, into a stiff paste with steamed potatoes. When the bird has eaten to repletion and leaves its trough, take

it firmly but gently under the left arm, with the left hand open the beak, and with the right place divers and sundry boluses of the same food at the root of the tongue, and the bird will continue to feed for some time longer. Use judgment, and you will soon know when to stay. Now endeavour to induce sleep by placing the head under the wing: and, giving the bird a few gentle waves or rocking motion in the air, place it on the perch, and darken the pen by any convenient means (nothing better than an old sack). This course of feeding must be resorted to often during the day, and the fowl must be kept well supplied with drink; and this should, if possible, be milk. Broth will do, but milk is to be preferred, both for fattening and for the colour of the flesh.

Should this plan be followed out on birds of from five to nine months old they will fatten more quickly, but the price obtained will not be much in advance of that for the older birds.—LEIGHTON.

P.S.—A few words as to the communication from "E. C. C." The balance sheet I will give *in extenso* when this series of papers is concluded, and I do not fear to meet the various objections urged by this writer. I will now take exception only to the conclusion of the first paragraph. I disclaim having put myself forward as an "authority." In my humble papers I have simply given the results of my own experience.

PIGEON-ROTTEN FEATHERED.

CAN you oblige me with a remedy for a Pigeon that has lost a great many feathers? and those she has left hang very loose, and come off on the least touch. Last summer she was almost naked, but kept in good condition, and went on breeding as usual. She is an Almond, and a valuable bird. I was recommended to give her a cold bath every morning, but the first almost killed her; and if she wanted a cold bath she would take it herself, as there is always water for them to do so.—L. A.

[Your Pigeon is what the fancy call rotten-feathered. I do not know of any cure, but fitness will most likely increase the disease. I would advise a less stimulating diet and the frequent use of the cold bath.—B. P. B.]

WATER FOR THE PARROT TRIBE—PRESERVING HAMS.

HAVING seen several articles in your Journal lately on Parrots, I fancy I may add a little weight to "E. H. D.'s" testimony in your last Number, by stating that I have had a Parroquet (which I presume to have similar habits to the Parrot) for twenty-three years, and it has invariably been indulged in a soup-plate of water for a bath, its cage door almost always open for it to come out, and having also a large saucer of water inside its cage. I might add that its food has been hempseed in one tin, and sopped bread in another, with a bit of everything that it sees any one eating (which it is sure to ask for in its way). Fruit of every sort it is very fond of, particularly oranges.

To Preserve Hams.—In reply to "A CONSTANT SUBSCRIBER" (Journal of 7th May), also, I would suggest his putting them into malt dust or "cums," taking care they are well covered, but this is no use if the enemy has deposited his eggs before, and great care ought to be taken that the hams do not lie about before going to be smoked, as also after they are sent to the smoking-kiln. The malt dust ought to be fresh, and from high-dried malt if possible. All placed in a box or tub in a dry place and kept off the floor a few inches, covered also on the top.—OBITER DICTUM.

I USED to apply a mixture of one stone and a half of common salt, half a stone of coarse brown sugar, half a pound of saltpetre, and, perhaps, as much black pepper, about two stones in all, to fifteen or sixteen stones of pork, turning the hams and rubbing them afterwards, and then smoking them with sawdust of fir wood. I have been quite as successful with a friend's receipt, which makes the salt one-half bay, and one-half common, adding treacle instead of sugar, and applying it at the end of a fortnight, turning and rubbing the hams twice a week during that fortnight, and also for a fortnight after, and washing them with lukewarm water before hanging up to dry. This receipt contained also saltpetre and pepper, but no smoking, which is a matter of

taste. Rubbing is a great matter, and turning each time. The winter months are, of course, the proper season for curing, as there is less risk.—A. S.

NEW BOOK.

BIRDS' EGGS AND NESTS.—We deprecate without any reserve the confinement of our native birds in cages and aviaries, for we look upon it as needless and indefensible cruelty, and we fully sympathise with the kind-hearted sanguine-temperamented gentleman who, regardless of consequences, and defiant of opposition, seized upon every Lark's cage that came within his reach and liberated the bird it confined! But we have not such repugnance to the taking of birds' eggs. It does not cause the parents much vexation—it is not cruel, like robbing them of their young—or, at all events, the vexation is very transient, for we have known a pair of Sparrows whose nest was taken on Monday, at work energetically constructing another on Tuesday morning. Besides, it is necessary to check the excessive production of birds as of all other animals, and the most humane way of doing so is by depriving them of their nests and eggs.

Nor need this minor branch of fowling be mere wanton destruction. Every one has a taste for collecting something, and we have seen this taste for collecting the eggs and nests of birds result in one of the most interesting of museums, and in a deep knowledge of birds and their habits acquired by their collector and arranger.

The nests of each family of birds, the Falcons, the Owls, the Finches, the Crows, &c., were grouped together; each nest was in a glass case, and in accordance with the place where it was found, whether in the branch of a tree, in the ground herbage, or elsewhere, copied exactly from Nature. Each nest contained its appropriate eggs. Each case was numbered, and the collector's M.S. catalogue under the corresponding number told where and in what month it was found, with notes relative to the parents' habits which the collector had observed. In each case, also, was a label containing the scientific and popular names of the bird of which the nidification was there.

The little volume before us is a very cheap and very trustworthy aid to any young person wishing to commence such a collection. It contains descriptions of the eggs of all British birds, whether constant denizens or migratory, and drawings of about 120 of them, the place where their nests are built, their form and other brief particulars.

One extract will at once enable our readers to appreciate the contents of the work:—

“OSPREY (*Pandion haliaetus*).

“The Osprey or Fishing Hawk, or Mullet Hawk, or Eagle Fisher,† builds its nest sometimes on a tree, sometimes on some part of an ancient and deserted building—always on the highest part, a turret or chimney for instance—and sometimes on a rock or precipitous scar. But a very favourite and almost characteristic site—speaking of the bird only as a British bird—is on some lone insular rock in a wild mountain loch in Scotland. I extract a very striking description from ‘St. John's Tour in Sutherland:’—‘The nest was placed in a most curious situation. About 150 yards from the shore there rose from the deep water a solitary rock, about 10 feet high, shaped like a broken sugar-loaf or truncated cone. On the summit of this was the nest, a pile of sticks of very great depth, evidently the accumulation of many breeding seasons, as the Osprey returns year after year to the same nest. How this heap of sticks withstood the winter gales without being blown at once into the water puzzled me. * * * The female Osprey allowed our boat to approach with 200 yards or so, and then leaving her nest sailed onwards with a circling flight till she joined her mate high above us.

“Having reached the rock, and with some difficulty ascended to the nest, our disappointment may be imagined when we found it empty. From the old bird having remained on so long, we had made sure of finding eggs in it. The nest itself, however, was interesting to me, perched as it was on the very summit of the rock, and composed of large sticks,‡ every one of which must have been a heavy burden for a bird of the size of the Osprey.

* *British Birds' Eggs and Nests*, popularly described by the Rev. J. C. Atkinson. Illustrated by W. S. Coleman. London: Routledge & Co.

† A translation of the Gaelic name of the bird.

‡ Some of the sticks, or rather branches, employed, are said to be $1\frac{1}{2}$ inch in diameter.

“In the centre of the pile of sticks was a cup-shaped hollow the size of boy's cap, lined with moss and dead grass, and apparently quite ready to receive eggs.’ ‘In another nest,’ says the same author, elsewhere, ‘we found two beautiful eggs, of a roundish shape: the colour white, with numerous spots and marks of a fine, rich, red brown.’

“The Osprey is met with from time to time in almost all parts of the kingdom, but more especially along the east coast; but it is known to breed nowhere in England now.”

WHITE FILM ON GOLD AND SILVER FISH.

HAVING seen an inquiry in THE JOURNAL OF HORTICULTURE, No. 3, by “A. B.,” asking for information about Gold and Silver Fish. He details their diseased appearance, and asks for a remedy. As I have a great many, and they were affected in the same way for the last three or four years. The first two years I lost a considerable number, and I puzzled over the subject a good deal. I found on catching the diseased ones, and putting them into a basin of clean water, and allowing them to stand on the hob of my fireplace, that they soon recovered.

But this did not stop the disease in the pond, which soon attacked others. I bethought me that it might be possible that the frogs had something to do with it, either by licking the fish, or the fish eating the frog-spawn, as the disease always begins at the time the frogs go into the water to spawn, so the last two years I had the pond emptied, and the fish caught, and put into a watering-pot until the pond was thoroughly cleaned out, all the frogs being caught, and committed to a hole filled with quicklime. After this the fish were returned to the pond, and the disease disappeared.

This spring I had one fish diseased. We set to work and emptied the pond, and destroyed the frogs, and had no more diseased this season.

Three years ago, when I called at Hampton Court Gardens, I saw all the fish in the most miserable condition, and at the time the pond was full of frog-spawn and frogs. I think if your correspondent will try the expulsion of the frogs he will save his fish.—JOHN SCOTT, *Merriott, Somerset*.

LUSUS NATURÆ.—A Pigeon was hatched recently in the collection of J. Rucklent, Esq., Grove End Road, Lisson Grove, having two heads and necks rising from just above the crop.

NIGHTINGALE—CUCKOO—SWALLOWS.—In compliance with “H. R.'s” request in your last Number to be informed of the first appearance of the Nightingale and Cuckoo, I have much pleasure in telling, that the first was heard by me so late (not until the latter end of last month) that I took no note of the time; but the second, the Cuckoo, I heard in the neighbourhood of Reading on the 4th of April, and the first Swallows were seen by me at Reigate on the 11th of April.—F., *Redhill*.

BEEES IN THE HIMALAYAS.

BEEES are pretty generally domesticated in the middle and higher hills, but are rarely seen in the lower valleys. If a little care and management was bestowed on them they would be very plentiful, and might be a source of considerable profit. The domesticated bee in the villages of Gurwhal, and the wild one in the forests, is one and the same insect, and swarms often come from the forest into the houses, and leave the houses for the forest. Those that may be called domesticated are kept in the walls of the houses or outbuildings; but no trouble is taken with them, the young swarms even being left to go where they like, and the only time a Puharie ever troubles himself about his bees or their hives is when he takes the honey. In building a house, or any substantial outbuilding, small oblong apertures are left at intervals in the walls, generally of the lower story, about 12 inches by 9 inches. An oblong piece of board, with a small triangular hole in the centre, secured in the wall while building, closes the aperture outwardly; and a similar board without any hole, and made so as to be removed at pleasure, serves a similar purpose inside. Six or eight of such hives is the usual number made in a moderate-sized house. Sometimes a portion of the hollow trunk of a small tree, if a hive can be found adapted to the purpose, is made into a hive by closing each end with circular pieces of board, and building it into the

wall. All is now left to chance for swarms of bees to take up their abode in the hives. They may all get occupied, or only two or three, or perhaps none. To take the honey the board which closes the hive inside is taken off, and a piece of ignited dry cowdung is held inside, and soon fills it with smoke. The bees hurry out and the combs are separated from the roof of the hive with a knife, and drop into a dish held beneath to receive them, scarcely a single bee being killed. The board is then put in its place, and, as soon as the hive is free from smoke, the bees, which have been during the time clustering to the wall outside, re-enter it. The hives are taken twice a-year, in May or June, and September or October, but are sometimes opened to take out a small quantity in the interval. The honey taken in spring is very dark-coloured, rank, and of a disagreeable flavour, while that taken in autumn is white and of excellent quality. In the forest the bees make their hives in hollow trees, and sometimes in the cleft of a rock, and a great many of these wild hives are found and taken by the villagers.—(*A Summer Ramble in the Himalayas*.)

NEW BAR-HIVE.

I HAVE been favoured with the following sketch and description of a bar-hive which has been in successful operation during the last four years, and which especially commends itself to the attention of such amateur hivemakers who find that nails will not answer for bar-boxes, whilst dovetailing may possibly be beyond their skill.

The concluding note replies to such queries as suggested themselves to—A DEVONSHIRE BEE-KEEPER.

Size.—Inside measure 12½ inches by 12½ inches.

Back, front, and sides.—One-inch stuff; window back and front.

Top.—Three-quarter-inch mahogany 14½ inches by 14½ inches.

Bars.—Three-eighths-of-an-inch mahogany, in two pieces, fastened together with two brass screws well greased, the top piece 14½ inches by nine-sixteenths of an inch, and the bottom or comb-bar 12½ inches by seven-eighths of an inch.

The two sides will be 11½ inches wide; the back and front 12½ inches wide, and in depth three-eighths of an inch less than the sides.

Glazed with two panes of glass about one-eighth of an inch thick, 12½ inches wide at top, and 12½ inches at bottom, depth three-eighths of an inch less than the back and front of hive, pushed into grooves in the sides of the hive. The extra quarter inch in width prevents their falling through when the hive is moved before the bees have fastened them.

Openings for working-glasses and supers are in the top of the hive at the sides, as I find this arrangement interferes less with the honey storing and breeding than openings in the centre; the two outside bars have the top cut away down to the comb-bar.

Slides.—Space for zinc slides cut out of the top of the hive.

In removing bars in warm weather a knife is seldom required, as the uniformly smooth surface presented by the glass back and front will generally allow the comb to slide up the glass upon gentle force being exerted; but should it be necessary to use the knife, the two brass screws in the top of the bar will easily draw,

and the top can then be pushed either backwards or forwards sufficiently to allow the knife to be inserted, the screws then replaced and the comb removed with facility.

In reply to your queries, which I will take in the order that you make them, I have to say—

1st. That the moisture does condense on the glass at back and front, but if the hive be set on a gentle slant it runs to the floor-board and quickly out at front.

2nd. As respects protection, I have to acknowledge with shame that I deserve a very different fate from what I have experienced this winter, for I was too lazy to set up a covering which a storm in the autumn upset, and, consequently, my hives have been exposed all the winter, and yet I have not lost any of my stocks.

3rd. I cannot say that expansion of the woodwork does not take place in the winter; but if so, the summer sets all right again, and I have never suffered any inconvenience from this cause.

4th. The bees do sometimes cement the top-bars, but they are easily divided with a knife.

5th. If you will refer to the description forwarded to you, I think I have there stated that the glass sides (one-eighth of an inch thick) are carried up to within three-eighths of an inch (the depth of the bars) of the top of the back and front, thus leaving a glass ledge for the bars to rest upon should the screws be withdrawn.—E. H. B.

THE WOODBURY COMB-BAR.

IN page 389 of our last volume we inserted a communication from "A DEVONSHIRE BEE-KEEPER," describing this improvement on the ordinary comb-bar. To those who cannot obtain guide-comb for starting swarms in bar-hives it will prove very acceptable, whilst as an adjunct to guide-combs, it is also valuable in producing greater regularity in the construction of combs than is usually attainable.

The following illustrations show how the "Woodbury Comb-bar" has been adapted by Messrs. G. Neighbour & Sons to Taylor's amateur bar-hive:—

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 1 is a representation of the stock-box and floor-board with the crown-board elevated to show the bars in their places, and the slides and window shutters withdrawn.

Fig. 2 is the improved comb-bar in perspective, whilst Fig. 3 represents a transverse section of it.

Fig. 4 shows the hive with honey-box and roof complete.

We can recommend these hives as being moderate in price, and well adapted for the use either of the amateur or the scientific apiarian, whilst the well-known character of Messrs. Neighbour & Sons, is a sufficient guarantee of good materials and workmanship.

ADVENTURES OF A LIGURIAN QUEEN.

THE following interesting letter from your esteemed correspondent "B. & W." details the adventures of the first Italian queen bee which I have succeeded in raising this spring. I am sure all the apian readers of the JOURNAL OF HORTICULTURE

will anxiously await the sequel to the "Adventures of a Ligurian Queen."—A DEVONSHIRE BEE-KEEPER.

"May 13, 1861.

"MY DEAR SIR,—Your letter of Friday announcing the departure of the Italian queen took me greatly by surprise on Saturday morning. It was a miserable day throughout, very stormy and wet and cold—in fact, here it was blowing a hurricane, which strewed my garden with the leaves and branches of trees, &c. However, I sent off a man on foot six miles to H— after his dinner, and in the meanwhile I myself successfully effected the formation of an artificial swarm in my bee-house without any trouble out of my strongest stock. It was very full of bees, all of which were at home, and in a very impassive state. You will understand that I drove the bees from their upturned box into an empty one of the same size placed over them. A fair-sized swarm ascended after the queen in five minutes, leaving a large population still behind. I never knew bees so quiet; only one attempted to sting, which I accidentally squeezed with my glove. The door of the bee-house being open, the few bees that rose found their way, I hope, to their old home ultimately, although the storm without was scarcely resistible by a bee on the wing. All was over, and the two hives in their respective places by three p.m. The old hive is in its old place, the other one (the swarm) close by on the same shelf, but shut up, as I was anxious to be certain I had got the queen with them. I can at any time close the communication between any of my hives and the open air by simply sliding them, board and all, a little to the right or left of the aperture through which they descend into the sunlight.

"It was not till five o'clock that my man returned from H— with the little casket containing the Italians. On substituting a piece of glass for the unscrewed lid the travellers were discovered hanging in a state of chilled repose from the bit of network which contained the food with which you had supplied them. You have adopted an excellent plan for their travelling comfortably and safely. The queen was the liveliest of them, and an unmistakable Italian; but I thought her small*—smaller in proportion than her subjects, which certainly appear larger than our English bees.

"Acting on Huber's experience, I thought it advisable to wait twenty-four hours before attempting to give the new queen to the hive which had lost its own. It was accordingly about three o'clock, p.m., the following day (yesterday) when I introduced her to her new subjects. Everything had been got ready beforehand, so that when the time came I had nothing to do but to withdraw a zinc slide from the hole at the top of the hive. For I had placed the little casket close to this hole, resting on one of its sides, and open to the hole. Over all was placed an empty box with glass windows, through which I could watch all that was going on.

"I should mention that I had previously drenched the Italians with richly-sugared water (bee food), and poured a quantity of this over the top of the hive, so as to divert the attention of the English bees, and prepare them to receive the new comers kindly. Everything at first succeeded as I could have wished. No irritation was visible on either side. The bees fraternised amicably as the Italians gradually roused from their state of torpor and became warmed by the genial air from the hive below, some of them even descended into the hive. All this, however, took up some time, till, getting impatient to see how the young queen would be received, I stirred them up with a bit of tarred string let down through an aperture in the top of the covering-box. This caused her Italian majesty to disengage herself from her own people, upon which she was immediately laid hold of by one or two English bees, and dragged down into the hive in spite of all resistance on her part; for she was in full strength apparently, and managed to get away from them once at least. And now all was changed. The hitherto peaceable hive was thrown into utter confusion—so much so that I doubt if the bees had yet discovered the loss of their old queen. That they were aware of it now there could be no doubt, as they shortly set up that joyful hum with which you are familiar, after a frantic rush of the bees all over their combs. This hum leads me to hope that the Italian queen may have been ultimately set at liberty and enthroned; but I know nothing of her fate. As to her former subjects a general massacre of them took place immediately after their queen had been seized, and their dead bodies continued to be dragged out of the hive for

an hour or two afterwards. It must have been half-past three o'clock, p.m., when the queen was carried down, but the hive continued in a highly disturbed state all the evening; as was still the case when I inspected it at nine o'clock for the last time. This morning, however, all was tranquil, and the bees have been busily at work carrying in pollen in large quantities, just as if nothing had happened. It only remains for me to wait patiently till I can catch sight of the queen, or see some of the future progeny of the hive.

"I should mention that this hive had several drones in a high state of vigour yesterday; but the bees of all my other hives have got rid generally of their drones this cold week.—Yours truly, B. & W."

HOW TO CURE AND PRESERVE HAMS.

IN answer to "A CONSTANT SUBSCRIBER" relative to the preserving of hams and keeping the "jumpers" from them, I will, with your permission, go before and beyond the question—first by giving directions for cutting up my pig and then salting him.

For good bacon, and in defiance of the vermin, I have successfully adopted the method during twenty-seven years. It is a Shropshire plan, generally performed in the surrounding country about Ludlow, and it is one I intend to use to the end of my chapter. Should I require a good second to the advice I am about to give, I would appeal to Mr. Beaton, as one not likely to have let slip an opportunity of making himself acquainted with so important a subject when he lived in the neighbourhood and cut down old apple trees there, which I did myself on the other side of the Thame about the same time; though, instead of consigning me to where they would him, the "old women" convened in an opposite and Don Giovanni sense of the word—to drive me out of the country altogether!

But to my pig. Place him on a bench with his back downwards, and, taking as a guide the sticking-place, cut its head off, plying the knife just behind the ears where there is a joint. Then turn the pig on its belly; and with a line chalked and strained, form a straight mark centrally along the backbone the whole length of the pig, and, following the mark with the knife, cut down to the bone. Then turn the pig again on its back, and cut through what little flesh there is on each side the backbone, to facilitate the operation of cutting it out, which is partly or wholly done with a cleaver by separating the ribs on each side. Detach one side or flitch, and lay the side with the backbone on the bench, and remove the backbone. Commence cutting shallow over the shoulder to remove the spareribs and lean meat adhering, remembering to leave a very thin portion of lean upon the fat of the flitch. Cut the ham from the flitch in a decided and rounding manner, and saw off a small piece of the bone that protrudes from its centre. Cut off the "whip,"—a thin piece of fat and rind from the neck in continuation along the belly of the flitch, to give it a neat appearance; odds and ends of which, wherever from, if fat, to become melted with the lard. Cut the feet off a little below the knee-joints, and trim off what appears uneven upon the ham and shoulder. Cleaver the backbone into three or four lengths, and operate on the other flitch as before. Now take the head. Cut from the centre of the jaws, guiding the knife just below and to the back of the ears, to facilitate the separation of the cheeks from the jowls, which is completed with the cleaver, cutting the whole of the upper part of the head from the lower part. Extract the tongue with the knife, and with the back of the cleaver crack through the lower jaw 4 inches from its extremity, flea it up with a knife, and cast that part of the detached bone to the dogs. Cut the snout away entirely just under the eyes with the edge of the cleaver. Then cleaver through the head midway between the ears; take out the brains, put them in a basin of water, and cleaver the bones away under the ears, to the degree that the finger may be intruded beneath the sockets to force out the eyes preparatory to their extraction; and, as a finale, cut off the ears, and trim from them extraneous matter, hairs, &c., and allow the feet to undergo the same operation. Keep a cloth or two at hand, and allow all the evolutions to be conducted in a clean and orderly manner.

And now specially for "CONSTANT SUBSCRIBER'S" question. Suppose two hams weighing 34 lbs. Lean them on end, hooks uppermost, as soon as the pig is cut up, for three or four hours or so to drain the blood from them. Then with a cloth press firmly from the rind obliquely up the face of each ham, and what blood is perceived to ooze from two veins situated, one

* She is really a fine young queen. All queen bees increase very considerably in size after they begin to lay eggs.—A DEVONSHIRE BEE-KEEPER.

quite and the other nearly centrally, wipe away with a cloth. Continue pressing so long as blood continues to appear, and take particular notice where the veins are situated. Now turn the hams on to their faces, and, with a hard dried lump of salt, rub their rinds for twenty minutes; turn them then, and place them on the station, whether of wood or stone (stone is best) which should slope slightly to allow the brine to run freely away as the salt liquifies. Then press with the fingers a little ground black pepper into the openings of the veins, and around the central bones; also press some well in at the hocks where the feet were cut off: this prevents the weevil—a small black fly which appears about March—using these places as its egg-depositories, to become colonies of maggots to penetrate and spoil the hams, but they cannot become life in pepper.

Having previously mixed and dried before the fire 2 ozs. of saltpetre, and about 4 ozs. of moist sugar, with a few pinches of pepper, divide it into two parts, and spread it on the face of each ham most bountifully on the thickest part; rub it in slightly with the fingers, reserving a pinch for the end of the hock. Now lay on the salt (which has been previously rolled and dried by the fire) half an inch thick over the hams, even to the hocks, at which places press in as much as possible. Smooth all over with the palms of the hands, and leave them in a workmanlike manner. Attend to them every other day; and on those parts from which the salt has disappeared add more, and so on for the space of a fortnight. The exact proportion of salt to advise is difficult to arrive at, as this depends so much upon the weather, which it happens to be frosty, the salt remains in its unliquified state so much longer; but as a rule, in which one cannot err, cover the bacon entirely, and as it wastes still add more salt. The larger the hams are, in proportion, so much longer time will they take in the process of salting. If they are a third heavier than those specified, a week longer will be required. If double the weight, about six weeks; though, in either case, they will require resalting but once entirely, dividing the time in each case as a medium to do this. And now supposing our limited fortnight to have expired, clear off the old salt from our 34-lb. hams, and “dab” them with a dry cloth till they appear tolerably dry, at the same time wiping beneath the place whereon they rested; after which, with plain salt only, allow them to undergo the operation as at first. Attend to them another fortnight, and then another clearing-and-dabbing operation, with the addition of a little flour dredging for appearance’ sake; which done, form a coarse piece of brown paper bagwise over the end of each hock, and noose it around with a stout piece of cord, which will form a loop to allow each ham to become suspended from hooks on a beam near the ceiling of the kitchen during their drying process, and so far from the fire and heat that they may not become rusty in consequence. The thermometer on our beam now as I write is at 60°; 75° it arrives at occasionally, but beyond that, as a permanency, is too hot. At the latter end of May I shift my bacon into a spare north garret, suspended on hooks where the temperature ranges about 60°.

In a period of three weeks or a month, or otherwise, so soon as the hams appear quite dry, and the saltpetre glitters upon them, envelope them in calico bags or something of that sort, and tie the bags tightly around the loop-suspenders as a preventive for dust and a caution against the fly, upon whose account take off the bags every month or six weeks and examine for fear of an intruder, as they are very insinuating, and great epicures, always preferring the hams to the shoulders or the flitches, though in default of the former attacking the latter: therefore, allow the eye to rest on them also. As soon as the bags are put on the hams will do to cook; but that is bad management, they are better and mellow for six or nine months’ keeping. I have kept flitches even for two years, and at that period of time the bacon was excellent.

The process of salting a whole pig is similar to the above, with this exception—not quite so much of the sugar-and-saltpetre mixture is required for the flitches, and on the fat part a mere fractional part will require to be sprinkled. Where the flitches lap over the shoulder-hocks introduce as much salt as possible at those places, otherwise they are apt to taint there. Lay the flitches as flat as may be, one on the top of each other, a shoulder at each extremity. The cheeks, faces, tongue, feet, backbones, &c., introduce between the flitches towards betwelling their courses, after having rubbed them with salt; and should there not be room on your salting-alone or board, I do my salting in an old beer-cooler, from which I catch the brine and toss it into the

liquid-manure tank. Place the hams on the top of the flitches. The spareribs may be salted or not, proportionally as they are required for consumption. On resalting place uppermost the flitch which was lying below.—UPWARDS AND ONWARDS.

VARIETIES.

FIXING SHIFTING SANDS.—In certain places on the seacoast, where the usual means employed for fixing the shifting sands, or dunes, have failed, such as planting the maritime Pine, certain kinds of Grass, Acacias, &c., it has been found that the *Ailanthus* is perfectly successful, even in the most arid places. A land-owner near Odessa, has for the last sixteen years planted a considerable extent of surface with this fast-spreading tree, and an almost impenetrable forest exists, where formerly was only a dreary, barren waste.—(*London Review*.)

TO UNITE STONE AND GLASS.—M. Bru, curator of the museum at Narbonne, has discovered that silicate of potash possesses, in the highest degree, the property of uniting surfaces of stone, glass, and pottery. It is applied with a brush to the surfaces which it is desired to bring into contact, and in a few days acquires a great solidity. It appears that the same material can also be successfully used in joinery, and for all the purposes to which common glue is applied. This discovery, which promises to be of considerable importance, was announced by M. Bru to M. Figuler, the editor of *L'Année Scientifique et Industrielle*, in the volume for the present year.

THE SOCIETY OF ACCLIMATISATION is more busy than ever. At its late meeting the contribution of a new silk-spinning worm, by Madame Drouyn de l’Huys, was hailed with great applause. The worm can be reared and fed in the coldest climate, and although the silk spun is of a coarse quality, its strength and durability are pronounced marvellous. Madame de Montesue also received the hearty thanks and congratulations of the Assembly for her donation of two Sugar Maples from Canada, with a memoir of her own experience on the cultivation and perfection of that tree in France. This lady has successfully established the possibility of producing sugar from the Maple in our climate, with a little more labour than exacted by the production of resin from the Pine trees in the Landes. The superiority of the Maple sugar over that extracted from the Beetroot was ably demonstrated by M. Puibusque, who suggested the experiment of acclimatising being made at once on the northern slopes of the Pyrenees and Alps, particularly in the coldest parts of Savoy, of Auvergne, and the Cevennes. The first plantations are forthwith to be made in the valleys of Barcelonnette, Briançon, and Chamounix.

OUR LETTER BOX.

GREY AND WHITE GUINEA FOWL (J. M. E.).—We have a letter for you, but have mislaid your address.

BANTAM UNABLE TO CROW (A Constant Subscriber).—We shall not be surprised to find that the fine weather has rendered advice unnecessary. We should give castor oil every other day, and feed sparingly on ground food mixed with water until his voice returned. There is internal fever. If he is artificially supplied with green food let it be lettuce.

PILLS FOR RHEUM.—At page 72 of Mrs. Fergusson Blair’s work, pills to cure rheum, it is said three grains of calomel and one grain of antimony. What sort of antimony does this mean? James’ powder, tartar emetic, or what? It is certainly too vague to be acted upon.—A SUBSCRIBER.

[We consider that tartar emetic is the preparation of antimony intended.—EDS.]

PARROT EATING ITS FEATHERS (All Anxiously).—Do not give the bird hemp-seed or bones. Keep it upon souped bread, nuts, and any fruit it will eat. Let it have a constant supply of water to drink, and a bath in a soup-plate of water daily. If it does not take the bath voluntarily, give it a shower-bath through the fine rose of a watering-pot.

GOLD FISH (H. W. M.).—The white film on the eyes of Gold Fish seems of a fungoid character. The cause is not known. Can you obtain river water for them? See what another correspondent says on the subject to-day.

LONDON MARKETS.—MAY 20.

POULTRY.

The glorious sun that has rejoiced all things has not been without his influence on the market. In the dread that chickens will grow “while you look at them” and that the weather will lower prices, many have been anxious to get their share of a dear market, and the consequence has been a decline in the value of small chickens.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 67.8° and 44.9° respectively. The greatest heat, 85°, occurred on the 2nd in 1834; and the lowest cold, 32°, on the 31st in 1857. During the period 141 days were fine, and on 90 rain fell.

CROSS-BREEDING IN PLANTS.

FERTILISATION OF LESCHENAULTIA FORMOSA.

UCH obliged am I to Mr. Beaton for his very interesting answer to my question. When Mr. Beaton says he does "not know of an instance of the natural crossing of varieties," I presume he intends to confine his remark to the plants of the flower garden; for every one knows how largely the varieties of the Cabbage cross, as likewise

the ease (as I know from careful trial) with Radishes and Onions. It was this fact which led me to suppose that varieties of flower-garden plants would naturally cross.

I can quite understand, after reading Mr. Beaton's remarks, that it would be very difficult, perhaps impossible, to detect such natural crossing from the degree to which most of these varieties vary. I should, however, think that those who raise for sale seeds of distinct varieties of the Hollyhock, Stocks, &c., must know whether it is indispensable to keep the parent plants apart.

I will not trouble Mr. Beaton again if he will have the kindness to procure for me answers on one or two points quoted in his paper (June 26, 1860) from the "king of British cross-breeders"—namely, whether I understand rightly that the white *Anemone apennina* seedling in a mass with the blue (*Anemone apennina*?) produced many pale shades? For this seems to be a case of two varieties naturally crossing, though I want to know the fact for another reason—namely, because *Anemone* does not secrete nectar; and secondly, whether *Mathiola incana* and *glabra*, which the writer speaks of as "crossing freely," were artificially crossed.

Mr. Beaton's statement (July 24, 1860) that if the pollen of five kinds of *Geranium* (I presume what botanists call varieties, and not what are called species, are here referred to) are placed on the stigma of a flower, one kind alone takes the lead and produces an effect, seems to me a most curious observation. It is, I fear, unreasonable to ask for a few precise cases on this head; for, as I gather from Mr. Beaton, it must be difficult to know whether one or more kinds have produced an effect, owing to the great variability of crossed varieties.

I have been delighted to observe how strongly Mr. Beaton insists that "not a flower in a thousand is fertilised by its own immediate pollen." This is a subject

which I have attended to for the last twenty years. From my experiments on a small scale I would not venture to put the case nearly as strongly as Mr. Beaton does; but on the other hand, some of the plants which Mr. Beaton advances as self-fertilisers seem, as far as I can trust my own observations, doubtful. I will give one instance, as it might possibly induce some one to try the experiment. *Leschenaultia formosa* has apparently the most effectual contrivance to prevent the stigma of one flower ever receiving a grain of pollen from another flower; for the pollen is shed in the early bud, and is there shut up round the stigma within a cup or indusium. But some observation led me to suspect that nevertheless insect agency here comes into play; for I found by holding a camel-hair pencil parallel to the pistil, and moving it as if it were a bee going to suck the nectar, the straggling hairs of the brush opened the lip of the indusium, entered it, stirred up the pollen, and brought out some grains. I did this to five flowers and marked them. These five flowers all set pods; whereas only two other pods set on the whole plant, though covered with innumerable flowers. The seeds in these pods were bad, or else I had not skill to make them germinate. I became so strongly convinced that insects would be found concerned in the fertilisation of these flowers, that I wrote to Mr. James Drummond, at Swan River in Australia, and asked him to watch the flowers of plants of this order; and he soon wrote to me that he had seen a bee cleverly opening the indusium and extracting pollen; and a bee with its mandibles thus covered with pollen would very likely effect a cross between one individual and another of the same species. I have been told that this pretty plant, the *Leschenaultia formosa*, never sets seed in this country. I wish some skilful cultivator would rout up the pollen within the indusium in the manner described, and see whether he could not thus get seeds.—CHARLES DARWIN, *Down, Bromley, Kent.*

ARRANGING FLOWERS IN BOUQUETS AND VASES.

(Continued from page 132.)

HOW TO ARRANGE FLOWERS.

MANY books have at different times been written about plants and flowers, abounding in directions how to grow them, while there seems scarcely to be an instance of even a paragraph advising how to arrange them. It is a very difficult thing, indeed, to spoil the appearance of flowers, or to make them look ugly; but certainly a great many of those into whose hands they fall give them every possible chance of obtaining such an undesired distinction. And while one would have fancied that the mere love of flowers would have brought with it taste for grouping them, what is more rare than to see them really artistically put together?

When I say "artistically," my readers must be kind enough to understand that I speak of that triumph of

art in which no art is visible, when everything is easy and unconstrained because perfectly suited to its place.

There are a great many things to be considered in the art of arranging flowers; I have the profoundest respect for such finished combinations as now and then appear, but I am very far from claiming such success myself. All that I pretend is, that I know a good many little ins and outs as to the mechanical part, and we all know that good rules for combining colour apply to one thing as well as to another.

Moreover, the Germans and Russians very far surpass the English generally in their floral decorations; and having some time ago made acquaintance with a little German Comtesse far from the Vaterland, with its flower-decked salons and graceful pretty fancies, she and I found an endless source of mutual interest in our love of plants and flowers, whilst all belonging to them was so important to us both, that she taught me almost as readily as I learnt all that she could tell of those pretty and useful works.

In the art of wreath and bouquet-making, we have in the first place to make a judicious choice of the most appropriate flowers and leaves which, whether for vase or dress adornment, must be chosen with due regard to the place they are to fill.

After the choice of flowers and their colours we have to determine how best to gather them, and how to mount them; how to prevent their fading or falling prematurely from their stalks; how to make a foundation in a way to secure all these results the better; and, lastly—I was very much tempted to write lastly—comes the mere actual placing of the flowers themselves.

There is a good deal to be said on all of these points; and as, in great measure, the same preparatory cares are necessary both for wreaths and bouquets, I have to request that the grounding may be deemed not unworthy of a little pains and time.

First. Let us consider what flowers may be chosen judiciously. Now, it is a notorious fact, that at least half of the young ladies who wear bouquets—unless the intervention of some provident French milliner saves them from the danger—wear such flowers as by no means suit their dresses, and that they arrange vases with quite as little adaptation to the colours and things around. It is, of course, exceedingly desirable the flowers should be of the same colour as the ribbons and the dress they are to be worn with, or for a table that they should be somewhat suited to the general decoration; but although that they should be suited is quite unexceptionable and altogether correct, we find the fact of their being of the same colour is by no means the likeliest course to adopt for reaching that happy result. Very few flowers will perfectly match with colours of human dye; and where they do not match, the human workmanship is very apt indeed, if contrasted with them, to show itself inferior.

These remarks, however, are only *en passant*. The business before us is to make what are in themselves good bouquets; and even so I must ask my readers if they can much improve on simple cerise or scarlet flowers with green and white relief; or pale sky blue and white, interspersed with little knots of pink; if any pink that it may have to go with, can indeed be exactly matched in shade. With pale blue, again, a still paler pink is a very charming contrast, and one which harmonises far better than any blue would do, though in this case little tufts of blue come in most pleasingly amidst the pink and white.

Pink answers best with mauve, perhaps, though primrose is not quite out of the question. Primroses sometimes will answer well with a pattern traced upon their ground, of the deep violet-coloured Pansies, or of large double purple Violets.

Lastly. With black costumes I consider the great secret of preparing a fitting bouquet is to have the chief part of the flowers very dark, and a few bright little

leaves and tendrils, or veins and edgings, just to catch a light and brighten up the whole. Light flowers look very poor on a dark background; while dark flowers are distinctly seen, and seem to acquire only a richer shade.

Having said so much of colour, I fear I shall at once convey a shock to the feelings of some of my readers by saying, that with these conditions as to colour, and a reasonable degree of judgment as to choosing prettily formed fresh flowers, I am so utterly lost to all respect for grand aristocratic hothouse plants, as to recommend the most sovereign indifference as to "what the flowers are," or "what they cost;" maintaining, on the contrary, that where a common every-day flower will answer equally the desired result, it is quite indefensible to pass it over merely because it is within reach of all. And, besides, how much more talent there must be in making a beautiful bouquet out of a few common flowers, depending for their *recherché* appearance on the good taste which dictates their grouping.

One of the very best white flowers I know for this purpose is the common white Lilac; the large pyramidal cluster being cut into small pieces, and each piece mounted with wire on a slender piece of stick. White Violets, again; white Hyacinths, the bells mounted also two or three together. I am told that white Alyssum is not to be despised, and white Verbenas and Geraniums are always on the list.

The Lilac is a useful flower to bear in mind, as it forces easily and well; and Chinese Primroses are amongst the best of winter flowers if duly brushed over with gum water underneath each flower. The pretty little *Deutzia gracilis*, Snowdrops, Azaleas, and many kinds of white Roses are also of the essential snowy white; and so is the exquisite little scented Clematis, which is amongst the very best of edgings; but common white Jasmine rarely looks well, or lasts long to wear. *Stephanotis* no one would doubt about adopting for a bouquet; and the same remark applies to the sweet white Cape Jasmines and Gardenias. White Myrtle blossom is often to be found in its prettiest half-open stage; and Orange blossoms, which are, however, not for common use.

The double blossoms of many shrubs, as of the Cherry, the garden Wood Anemone, and the wild Sweet Woodruff; Primroses also when they can be procured quite white, and double white Hepaticas; with many others which will occur to every one.

I say much about white flowers first, because they are always wanted, and it is, in fact, rare to get on satisfactorily without them in any bouquet arrangement; otherwise it will be sufficient in designs to mention special flowers, and to go on chiefly with the mechanical part of our pleasant work.

WREATH DESIGN.

Wreaths of mixed flowers are difficult to manage. A delicate eye for colour, and the lightest of hands for combining the flowers are required to prevent their turning out clumsy garlands.

The easiest to make are those of one flower, and they are much the prettiest. At this very instant one is furnished by my memory as so pretty that I cannot resist describing it instead of the mixed *jardinière*.

It was of Thorn blossom, scarlet and white. The white May or Hawthorn looks so exquisitely fair and pearly, and both kinds continue long unfaded. The little shoots of small-leaved Myrtle, or single leaves of some rather pale-coloured evergreen, are best for the foundation. When the May blossoms have been gathered with the morning dew upon them they should be put in water in a shady place, not in great branches, but the little heads, 3 inches long or so, cut off and put in water separately.

We should never handle flowers much, the lightest touch is sufficient to bruise and bend them.

Two long branches of Periwinkle form the very best of

stems. The leaves are evergreen, and the stems are moist and green. I have heard that taking out a little of the pith and through the slit-up bark laying the May flower stalks therein, answers well for keeping the flowers all the fresher. However that is, a few little bunches of the half-open Hawthorn, and here and there a single spray of scarlet or of crimson, do look very lovely mounted on the bine. The green foundation stems should be tied together with a piece of green Berlin wool, beginning always at the upper end and working towards the root end. The first tiny piece of May being laid upon the stem, the wool should be wound on down it, and after three or four rounds a slipnot should be firmly drawn to render the flower steady.

Next should come a little spray of green; tiny bits of Larch, look very pretty; and then, again, more May, and double or triple groups with one or two of the bright little scarlet clusters.

The flowers should not be arranged too closely, but bound on at short intervals broken by the smaller buds and green, and at the centre or sides where a degree of fullness and of massiveness is required, the flowers should be arranged in small knots before they are mounted on the stem itself.

Each side would require about three knots of flowers, and they should be arranged either with perfect exactness as to colour and place, or without any attempt at all at evenness.

Many persons are in the habit of winding a very narrow green ribbon evenly down the stem, folding it frequently in a slope to induce it to lie smooth.

For the head, or for hanging, German-like, on a picture-frame, the wreath is often made most easily by beginning at each end and working towards the centre. When a high coronal is to fill the centre its knots of flowers serve to unite the two sides, and where the centre is small the join is best at the commencement of the side groups.

I hope my readers will not try to add any other flowers. But if a few Fern leaves should be put in, I think they would greatly add to the air of lightness.—E.

(To be continued.)

CRYSTAL PALACE FLOWER AND FRUIT SHOW.—MAY 18.

ALL the plants were better arranged for effect this time than they have yet been at the Crystal Palace. There were no plants set up in the centre of the great transept to intercept the view from end to end. The old kinds of Azaleas, which were very finely bloomed and very numerous, were placed in the four corners of the transept, and the newer kinds in collections followed along one side of the south nave, where also were the Cinerarias, Calceolarias, and mixed collections of new and old plants; and opposite to these stood the Roses and Pelargoniums, both very well done. The fruit stood along the centre of one end of the transept, opposite the grand orchestra, and on each side of that part were the variegated and fine-leaved plants; while the only two first-class collections of tiny Stove and Greenhouse Plants which competed stood across the end, and right opposite the great organ, the end under the orchestra and organ being tastefully evergreened with the cream of the Palace plants—such as Orange and Bay standards, Rhododendrons and smaller plants with finer foliage. At Burns' festival this part was highly decorated in the same style, but not so effective as on this occasion.

The Orchids occupied nearly the whole north side of the nave beyond the orchestra, and on the opposite side were placed the minor collections of stove and greenhouse plants. And the florists' cut flowers were placed in the extreme centre next the stove or tropical end; so that from the screen of the kings and queens at the head of the crystal fountain basin an uninterrupted view was obtained down to the Tulips at the extreme end. Any one who can distinguish a perspective from a bird's eye view could tell that by placing a group of plants in the centre of this vista, as we have seen done on former occasions, the one-half of the view is lost, and, in effect, the one-half only

of the Exhibition tells on the eye. That, then, is a practical illustration of the optical delusion caused by placing a mass of scarlet, or yellow, or crimson in the centre of a flower garden.

The blooms were not so many nor so early as they have been every May since I first went on the circuit in 1837; and the fine-leaved plants never looked so dull since 1838, when I first put up a whole tent full of odds and oddities of the kind at Chiswick Gardens. The florists beat the gardeners out and out at this Show—their Azaleas, Roses, Geraniums, and Cinerarias were indeed wonderful; but I could not get near their Pansies and cut flowers, for they were crowded round the whole day. But having just received a large basket of the best Belgian Pansies I hope to be able in the autumn to set up a ribbon-border of them for next spring.

The prize list in the last Number of THE JOURNAL OF HORTICULTURE saves me names and numbers, and the rage for florists' flowers comes in aid of my tale in the person of the best judge of them in the three kingdoms, who had free access to them before they were so crowded round.

There was no competition for the collections of Stove and Greenhouse plants, and Mr. Peed was the winner of the first and second prizes for them. He had the best grown and the largest specimen of *Impatiens Jerdonia* that has yet been seen—it might be 2 feet by 2 feet; one *Ixora salicifolia*; one *Leptodactylon californica*, a bedding-out plant well done in specimen; a fine *Tetralthea ericifolia*; and the usual amount of the genera *Aphelexis*, *Epacris*, *Pimelea*, *Eriostemon*, *Heath*, and *Azalea*. And in his second-prize score were these also, and, in addition, *Genetyllis Hookeriana*, *alias fuchsoides*, *Hypocalymma robusta*, and *Acrophyllum venosum*, with others, and a nice plant of *Adenandra speciosa*. Mr. Peed received £10 for exhibiting these forty plants.

Next came collections in twelve Stove and Greenhouse Plants, and among these were the best-grown plants at the Exhibition: one, *Tetralthea ericifolia*, 5 feet, or nearly so, across, was the finest specimen which Mr. Green ever exhibited, and he was the only gardener there who spelt *Hedera* properly—a name which seems to puzzle all other exhibitors of it. Such false spelling is shameful; the blame, however, ought to rest on the old Horticultural Society, and on the Regent's Park people, who actually taught gardeners to despise the spelling of the names of plants unless they were paid to do so by a prize, instead of being disqualified from winning a prize for wrong spelling.

Mr. Green's next best were numerous—as *Allamanda grandiflora*, *Franciscæa calycina*, *Pimelea Hendersonii*, *Rhododendron formosum* (very fine), *Aphelexis*, *Eriostemon*, *Polygala*; and his *Hedera*, or *Genetyllis Hookeriana*, *alias fuchsoides*, was called *macrostegia*. Is that a second alias? or are there two species which one cannot tell from sight?

Mr. Baxendine followed with the next best twelve, beginning with two *Heaths*, two *Polygalas*, two *Azaleas*, or rather three *Azaleas*, *Criterion* and *Iveryana* having been ingeniously worked on one stock, and both made an excellent plant; then *Aphelexis*, *Adenandra*, *Epacris*, *Rhinchospermum jasminoides*, and a very large thin plant of *Boronia Drummondii*.

Mr. W. Cutbush, nurseryman, Barnet, was next up to the mark. He had the two *Hederas*, *tulipifera* and *fuchsoides*; two handsome *Polygalas*, *Boronia tetrandra*, a fine *Adenandra*, and a finer *Erica*, *Victoria regina*, *Azalea criterion*, the very useful *Epacris lævigata*.

Mr. Chilman followed at the top of the Eight-Plant Collections. His very best was a fine *Acrophyllum venosum*, the best of the kind there; *Boronia Drummondii*, two *Aphelexes*, *Erica Cavendishii*, *Franciscæa confertiflora*, and *Polygala*. Mr. Kaile was second, a fine *Stephanotis*, *Rhinchospermum*, *Franciscæa*, *Vineæ*, *Epacris*, and *Aphelexis*. Mr. Page had the third best lot of eight, of which *Dracoecephalum gracile* was different from the above; and Mr. Tegg had a fourth prize in this class, he had two plants different from the above—*Oxylobium Pultenææ* and *Kemedia mophylla*.

The next class was of sixes; and here Mr. Page was first with *Boronia Drummondii*, *Hedera tulipifera*, a fine specimen; *Erica suaveolens*, also a fine plant; *Azalea*, and a repetition. Mr. Smith was second; *Rhinchospermum jasminoides*, and *Chorozema microphylla* being his best. Mr. Kaile was third with a good *Euphorbia splendens*, *Stephanotis*, *Erica Cavendishii*, *Aphelexis*, *Azalea*. Mr. Green next; his two rarest plants were *Daviesia nimbata* and *Azalea extranii*. And Mr. Baxendine had an extra prize, *Adenandra* and *Erica Beaumontiana* being his two best. Mr. Chilman was paired with Mr. Green in

a fourth prize for sizes, *Chorozeia Lawrenciana* and *Allamanda nerifolia* being different.

The next class comprised variegated and fine-leaved plants. Here Miss Burdett Coutts' gardener, Mr. Hutt, was first with huge specimens—a pair of great tree *Ficus*, *Agathaea* and *Dicksonia*, *Mousteria pertusum*, labelled *Philodendron persutum*, with a wrong natural order prefixed. How is that? *Croton*, *Maranta zebrina*, *Sansevieria zelanica*, *Dumb Cane*, and others of that stamp. Mr. Young had the next two prizes with similar plants, and a splendid *Cyanophyllum* hard upon 5 feet in height; *Theophrasta imperialis*, and *Aralia Sieboldi*. Mr. Bunney, nurseryman, Stratford, was next with a *Dicksonia*; a *Pandanus javanicus* variegated, *Pavetta japonica*, and *Ropala Jonghii*, differing from the rest as above.

There were several other collections of the same stud, including *Begonias*, which, by the way, do not improve by size. *Yucca*, *Justicia*, *Crotons*, *Caladiums*, *Dracenas*, *Farfugiums*, *Ropalas*, *Cissus*, *Aralia*, and such like in abundance.

Next in order of the schedule were the *Orchids*, a magnificent bank of very fine-grown plants, and a few very poor indeed. In the comparison of elegant—more elegant, and elegant—there were four kinds in array—*Dendrobium Paxtoni*, and three kinds of *Odontoglossum niveum*, perhaps, the most elegant, and there were two varieties of it. The other two were *Odontoglossum pulchellum* and *citrosimum*. But let us begin at the top of the ladder, where Mr. Stone showed sixteen plants of surpassing merit in cultivation—*Dendrobium Devonianum*, *D. macrophyllum*, with four very long spikes loaded with bloom, and loading the air with druggist-rhubarb smell; *Lælia purpurata*, with four blooms; *Ærides virens*; *Saccolabium retusum*; *Cattleya Mossie*; *Odontoglossum Piscatorii*, and *niveum*; *Epidendrum bicornutum*, a very fine *Oncidium ampliatum major*, and so on.

Mr. Peed was second with sixteen more moderate, of which *Calanthe masuca* and *Phalenopsis* were the two best and most differing. Next class in tens; and here Mr. Milford, and Mr. McMoreland his employer, stood fixed in the first prize. Here was the best-flowered *Lælia purpurea* I have yet seen, it had three spikes and eleven or twelve flowers fully expanded—the finest plant at the Exhibition. The Fox's-brush *Ærides*, or *Fieldingii*, was also very fine, and more of it here and there stamp it as one of the very best; *Phalenopsis grandiflora*, two varieties of the varied *Vanda suavis*, *Cattleya amethystina* and *Mossie*, and *Oncidium ampliatum major*, the poor man's *Orchid*, the easiest to do of all the *Oncids*, and the best-paying one when done. This same plant will last out the June shows, and likely enough some of the July ones.

Mr. Stone next, with *Odontoglossum gloriosum*, a variety of *niveum*; ditto *citrosimum*, a love of a thing; and *Phalenopsis grandiflora*, *Cypripedium Lowii*, with two flowers, *Ærides Warneri* and *Fieldingii*, *Saccolabium guttatum*, *Cattleya Acklandiae* with one bloom, and *Mossie*, with *Uropedium Lindenii*, which, if there be an *Orchid* from beyond the flood this must be it, for it is

"The queerest shape that e'er I saw,
For fient a wame it had ava."

Mr. Page was third with *Cattleya Skinneri* and *Mossie*, Fox's-brush *Ærides*, *Phalenopsis grandiflora* and *amabilis*, *Vanda insignis*, *suavis*, and *tricolor*. Mr. Woolley was next in tens with two *Dendrobium nobile* and *Paxtoni*; *Cyrtorchilum filipes*, *Ærides crispum*, *Vanda suavis* were the best.

In the class for six *Orchids*, Mr. Penny was first with *Lælia purpurea*, with three flowers; *Phalenopsis grandiflora*, with three long branching spikes; *amabilis*, with one spike; and *Cypripedium barbatum superbum* as the best. Mr. Bunney next with a fox's-brush of beauty, a *Phalenopsis grandiflora*, with three fine spikes again, and an *amabilis* with one spike, a *Saccolabium retusum*, and *Vandas* of the breed of *suavis*. Mr. McMoreland third, with *Cypripedium hirsutissimum*, the shop-rhubarb-smelling *Dendrobium*, also *nobile*, *Vanda*, and *Cypripedium*, all in self-ventilating pots. And Mr. Chilman was extra in the last of the sixes; and his difference was a *Cymbidium elchioranthum*, another queer thing as green as groudy. Mr. Stone and Mr. Smith also had extras in sixes. Mr. Stone had the only *Lælia cinnabarina* there, two elegant *Odontoglossums*, and *Ærides Lindleyana*. Mr. Smith, the beautiful *Odontoglossum pulchellum*, *Maxillaria aromatica*, *Acineta Barkeri* as his best. In tall Cacti Mr. Green is always first fiddle. Mr. Young was second, and Mr. Ashman third. The plants were not right out in bloom, and Mr. Young had the only "novelty," the name of a light red seedling, apparently from *crenata*.

AZALEAS.—Here was the first battle of the day, the rest being, in comparison, a volunteer review. Mr. Turner, of Slough, knocked the gardeners all over their barrows. Mr. Ivery came up from Dorking on purpose to do battle in earnest; and after assisting Mr. Turner to turn the right and left wings of the Trojans, they fell foul of each other about the newest fashion in Azaleas. There never were better Azaleas, surely never so many of them before on a field day. Mr. Turner had the first prize in the class for ten *Greenhouse Azaleas*, beginning with *Extranii*, as his highest colour, then *Murrayana*, prestantissima, variegata, *Perryana*, and *Glory of Sunning Hill*—a double dull red kind. Mr. Green, at his old north-east corner, was second with the yellow *sinensis*, *Stanleyana*, *Perryana*, prestantissima, *Sir Charles Napier*, semi-duplex maculata, and *alba magna* as his best. Mr. Carson followed opposite with the yellow in the centre, with *Exquisita* on one side, and *Lateritia*, a contrast, on the other side of his centre; then *Iveryana* and *Murrayana* to match in contrast again on opposite side of his key plant; then *Criterion*, *Bianca*, *Apollo*, *Carnea*, and *Double Red*, all remarkably well placed for effect. Mr. Peed an extra.

In the next class for sixes, Mr. Turner took the lead again with nice smaller plants. Mr. Page followed also with nice sizeable plants, of which coronata was the liveliest colour. Mr. Ivery and Mr. Penny being equal in the next run. Mr. Ivery had the best selection—namely, *Rosea elegans*, a very bright flower, *Rubra plena*, *Delicata*, *Iveryana*, and *Criterion*.

The next class turned the tables, and Mr. Ivery was uppermost with eight new kinds—*Variegata superba*, *Admiration*, *Rosea alba* (fine), *Distinction*, *Flower of the Day*, *Lord Raglan*, *Etoile de Gand*, *Rosy Circle*, *Due de Nassau*, and *Standard of Perfection*. Mr. Turner second, with *crispiflora*, a telling sort; *Gem* and *Perfection*, two exquisite; *Petunissellora*, a fine rosy kind with a violet tinge all over it; *Empress Eugenie*, and *Iveryana*, or one like it. And Mr. Ivery appears again with another eight—*Rubens*, variegata, *superba* again, *Criterion*, *Stanleyana*, *Gem*, and, indeed, the gem of all that were there—*Duchesse de Nassau* and *Beauty of Europe*.

In *Heaths*, Mr. Nobody was first. Mr. Peed second, with *Beaumontia depressa*, a large *ventricosa coccinea minor*, the best *Heath* there, and five others. Mr. Rhodes third—*albertus* and *ventricosa magnifica* being his two best plants. Mr. Chilman fourth, and *albertus* with *ventricosa coccinea minor* again were his best.

In the class for extremely Rare or Beautiful Plants, Mr. Williams had the best of it with a new *Lælia*, in the style of *Lælia purpurea*. Mr. Bull had those new plants which he exhibited this spring before the Floral Committee, and some others—as the fine single form of *Petunia Inimitable*, *Gymnogramma pulchella ramosa*, and several other novelties. Mr. Verschaffelt also sent over a collection of three or four kinds of variegated *Begonias* quite different from the usual forms. The Messrs. Lee sent their new very pretty small Fern—*Polystichum vestitum*, a gem of a thing. A fine specimen plant of their true *Cordylina indivisa* and *Sisyrinchium*, and others, which have been noticed in the reports of the Floral Committee. Mr. Bunney had a prize for six nice kinds of *Anætochilus*. Also Mr. Lacey for Ferns. The Messrs. Smith of Dulwich, for *Gloxinias*, and Mr. Young for a miscellaneous collection, in which were *Begonias*, *Caladiums*, and the only plant there of the *Alocasia metallic*. There were several other odds and ends; and Mr. Porter, Brixton Hill sent three kinds of yellow *Polyanthus* for spring borders. They were among the collections of yellow *Polyanthus* which I lately received. I called that morning on the best and oldest grower of yellow *Polyanthus* known to me. He had them first from the Youngs, of Epsom Nursery, has been at them these thirty years, grows them remarkably healthy in pots, and stages them like *Auriculas*, got nearly a white one this season, but never knew any of them come true from seeds. I fear to give his name lest his villa, his conservatory, and greenhouses, should be pulled down about his ears by idle people, who would press to see the man in the moon, if ever he got into print about flowers and experiments, half the world being perfectly daft on that one point.

FRUIT.—There was a keen competition among the fruit growers, and the bulk of the fruit was most excellent, particularly the Pines and Grapes. Peaches, Neectarines, and Cherries, and the Melons, were much smaller and far better flavoured than I ever before knew them at the Crystal Palace. The dish of British Queen Strawberry from Mr. Smith, of Twickenham,

was the finest sample of successful forcing ever exhibited anywhere. The *Violette Hâtive Nectarines*, and the black Cherries from Mr. Henderson, of Trentham Gardens, were also the finest-coloured fruit I ever saw at a May show; and the run for the best black Grapes between Mr. Henderson aforesaid and Mr. Hill, of Keele Hall, was worth a Derby day. The largest and the heaviest Pine—a noble Rothschild variety—from Mr. Stewart, Chatsworth, was indeed a surprising fruit. A strong man and a good judge lifted it for me, and he put the weight down as from 8 lbs. to 9 lbs.—it might be more. The next best Pines were of the smooth-leaved Havannah breed, with crowns as small as the comb of a Bantam cock. The best-flavoured Melon was the smallest fruit there of the Trentham Hybrid. It might be 1½ lb., was as yellow as an orange, and of the shape of a lemon: it was the finest-flavoured Melon I ever tasted. My teeth watered to taste another very small green-fleshed Melon of the true old Egyptian model; but as I was only once on the Fruit Committee, and did not yet learn how to judge two Melons at the same time without something to wash down the flavour of the first, I withstood the temptation.

There was one brace of Cucumbers which some one marked for seedling, and which some one else mistook for a Prizefighter, and sent it to the Show in a mistake, and some of the gardeners were much tickled at the idea of the thing. But as the prize list tells its own tale, I need not go over the same ground again.

D. BEATON.

THE FLORISTS' FLOWERS AT THE CRYSTAL PALACE.

NOTHING strikes one more forcibly, I think, at the early shows than the manner in which skill and knowledge of the habits of plants completely seem to defy all elemental difficulties. One heard all sorts of surmises and prophecies, that Pelargoniums would have no colour, and Tulips could not possibly be correct, yet when the day came it seemed as if, instead of one of the most unpropitious seasons on record, we had had the most favourable one possible. Another thing was forcibly impressed on my mind—viz., the truth of the observations I made on the arbitrary distinctions of florists' flowers. Mr. Beaton naturally took the Azaleas under his wing, and I the Pelargoniums, and wherefore one could hardly say. The former has had quite as much care bestowed upon it—has been improved, has endless varieties, and yet one does not quite recognise it as a florist's flower, while the latter is at once admitted as such. It needed no witch to at once pick out the first-prize collection in Pelargoniums, only two of which were exhibited in each class. Mr. Turner's are so unmistakably a-head, that though Messrs. Dobson & Son made a very hard push, yet there was an immense distance between the two collections. Mr. Turner's sorts (10) were—*Mr. Marnock*, a spotted variety; *Rose Celestial*, bright pink; *Desdemona*, fine white, with deep blotch on top petals; *Roseum*, very bright; *Admirable*, something in the way of old Carlos; *Guillaume Severys*, a French variety, not perfect in shape, light lilac purple with dark mulberry blotch, under petals spotted with same colour, very attractive for its contrast; *Fairest of the Fair*, very white; *Governor General*, an old but favourite variety, deep rose tinted with orange; and *Prince of Wales*, a very warm rose colour, with dark maroon top petals. Messrs. Dobson & Son had *Admirable*; *Sanspareil*, still, I believe, the prettiest of all the spotted sorts; *Rosalie*, pretty; *Fairest of the Fair*; *Eugène Duval*, a French variety, light purple with dark blotch; *Rose Celestial*; *Una*, fine white; *Symmetry*; *Aurelia*; and *Fair Ellen*, a good clear white. In eight Fancies, Mr. Turner was again first, with fine plants of *Modestum*; *Madame Rougière*; *Lady Craven*; *Cloth of Silver*; *Circle*, very dark and fine; *Queen of the Valley*; *Acme*, very dark and a splendid plant; and last, but not least, *Celestial*, a magnificent plant in full flower and excellently coloured. Messrs. Dobson and Son took second prize with *Madame Rougière*, *Captivation*, *Negro* (very dark), *Evening Star*, *Madame Van de Weyer*, *Attraction*, and *Bridesmaid*.

Cinerarias, which did not look particularly well, were contributed in four collections. The first prize for six varieties was allotted to Mr. Turner for *Bellissima*, a light blue, with rather pointed petal; *Alarm*, dark and good self; *Slough Rival*, pretty but hard in the footstalk, and not filling up the head of bloom well; *Perfection*; Lidgard's *Brilliant*, a fine blue edge; and *Queen Victoria*, dark crimson border, very good. Messrs.

Dobson & Son were second with *Duchess of Sutherland*, *Brilliant* (fine self), *Perfection*, *Mrs. Hoyle*, *Masterpiece*, and *Mrs. Marnock*. Mr. Burley, nurseryman, of Limsfield, took third with *Miss Godfrey*, *Perfecta*, *Beauty*, *Wonderful*, *Perfection*, and *Mrs. Dix*. The fourth was awarded to W. J. Fry, Esq., Baston Hayes, Bromley.

The queen of flowers was well represented, and as usual attracted a large number of visitors. Their delicious fragrance, as well as their freshness and beauty tending to draw large houses. For ten Roses in pots, the first prize was awarded to Messrs. Lane & Son, Great Berkhamstead, for immense plants of *Triomphe de Paris*, H.P.; *Coup d'Hebe*, H.B., a splendid plant; *Léon des Combats*, H.P.; *Gloire de Dijon*, Tea; *Baronne Prevost* H.P.; *Comtesse Mole*, H.B., large but rough and coarse; *Chénédole*, H.B.; *Paul Perras*, H.B.; *Souvenir d'un Ami*, Tea; and *Jules Margottin*, H.P., a beautiful plant. Mr. William Paul, of Waltham Cross, was second with *Louis Odier*, H.P.; *Souvenir de la Malmaison*, B.; *Souvenir d'un Ami*, Tea; *Baronne Prevost*, H.P.; *Chénédole*, H.B.; *Viscomtesse des Cases*, Tea, very yellow; *Paul Perras*, H.B.; *Paul Ricart*, H.B., very bright; *Jules Margottin*, H.P.; and a grand plant of *Madame de St Joseph*, Tea. Messrs. Paul & Son, third, with *Auberson*; *Charles Lawson*, H.B., very beautiful; *Narcisse*, T.; *Baronne Prevost*, H.P.; *Souvenir de la Malmaison*, B.; *Jules Margottin*, H.P.; *Géant des Batailles*, H.P.; *Nephtos*, Tea, very white; and *Paul Perras*, H.B.

For six Roses in eight-inch pots, to my mind a much more attractive class, Mr. W. Paul was first with *Victor Verdier*, a very large, rich, rose-coloured flower; *Empereur de Maroc*, very dark, of which an admirable drawing by Andrews appeared in Paul's "Rose Annual for 1860-61;" *Madame Boll*, very large, but in my opinion too rough and coarse; *Lelia*, a very pretty large-petalled flower in the style of Louise Peronny; *Madame Demaizin*, a fine and deep-coloured Tea; and *Triomphe de Paris*. Mr. Turner, of Slough, was second, with *Mathurin Regnier*, *Madame de Cambacères*, *Caroline de Sausal*, *Jules Margottin*, *Paul Perras*, and *Duchess of Sutherland*. There was a deficiency of colour in this lot; one or two high-coloured flowers would have given more variety to Messrs. Paul and Son third, and Messrs. Lane & Son fourth.

A nice collection of cut Roses came from Mr. W. Paul, amongst which were fine blooms of *Eugène Appert*, H.P., a very fine high-coloured flower; *Madame William*, a new Tea; *Baron Gouella*, B., a large crimson-coloured flower, very good; *Homère*, a mottled rose-coloured Tea, something like Bougère; *Empereur de Maroc*, H.P.; *Cardinal Patrizzi*, H.P., both very dark; *Triomphe de Lyon*, H.P., one of the new Roses of last season, a fine high-coloured flower; *Buffon*, H.P., a dark scarlet, also new; and some fine blooms of *President*, which is really a grand Tea-scented Rose.

A group of six shrubby Calceolarias, exhibited by Mr. Burley, nurseryman, Limsfield, Surrey, deservedly attracted great attention. They were quite bushes, covered with bloom, and in size and colouring approached very near the herbaceous kinds. They were well grown, and reflected great credit on their raiser, for they were all seedlings of his own. They were—*Lord Raglan*, a fine reddish-scarlet, distinctly marked with crimson; *Emperor*, another large crimson-spotted variety; *Primrose Perfection*, clear yellow; *Lord Derby*, orange spotted with red; *Victor Emmanuel*, scarlet spotted; *General Havelock*, rich maroon. He also showed cut blooms of *angustifolia globosa*, a dwarf yellow kind for bedding.

In Cut Flowers, besides Roses above mentioned, were shown Tulips and Pansies. Of the former four pans of twenty-four varieties, and of the latter eight or nine of the same number. The Tulip is not everybody's flower, it involves a great deal of trouble, is gaudy, and has no perfume; but I think few persons could have seen the pan of Mr. Turner's which took the first prize without admiring them. It is the fashion with some to run down florists, to speak of their conventionalities, &c.; but it was very strikingly seen in the difference between the first prize and even the second how correct those rules are, and how even they approve themselves to the uneducated eye. Mr. Turner's flowers were—*Royal Sovereign*; *Rosa Blanca*; *Fleur de Marie*; *Aglaia*; *Lady Hildair*; *Caliph*, ex., ex.; *Sir Colin Campbell*, distinct and clear feather; *Duchess of Cambridge*, ex., ex.; *Mary Headley*, fine shape; *Sarah Headley*, a fine feathered rose; *King*; *George Glenny*; *Laurence's Friend*; *Rose Celestial*; *Dr. Horner*, beautiful clear yellow with slight feather; *Seedling 648*, a flamed and feathered Byblosmen; *Rutley's Queen*;

Enchantress, a bright scarlet feather; *Duchess of Sutherland*; *Willison's Gem of Gems*, a fine feather; and *Seedling C 29*. Mr. Betteridge was second. Amongst his flowers were fine blooms of *Everard*, beautiful shape; *George Hayward*, a fine feathered bizarre of good shape; *Salvator Rosa*; *Strong's King*; *Seedling No. 2*, feathered Byblömen. Mr. Nathaniel Norman, of Woolwich, was third; and Mr. James Batten, of Clapton, fourth.

In Pansies the two best boxes were contributed by Mr. James, gardener to J. F. Watson, Esq., Isleworth; but the Judges had a considerable debate as to whether there were not too many dark selfs. This is an evil that requires correction. As a rule they are more easily grown; and the consequence is, that if an order is sent for twenty-four Pansies you are pretty sure to get nearly half dark selfs. Mr. James's flowers were—*Nepalese Chief*; *Colonel Wyndham*; *Rev. H. H. Dombain*, good dark; *Frances Low*, a beautiful clear yellow ground; *Father Garazzi*; *Maid of Bath*, fine white; *Alexander McNab*; *Eugenie*; *Miss Bill*; *Ladyburn Beauty*; *Alice*; *Duchess of Wellington*; *Mrs. Laird*, fine white ground; *Canary*, good yellow; *Duchess of Hamilton*; *General Young*; *Rev. J. Dix*, a good dark self; *Nymph*; *Jeannie's Rival*; *Miss Walker*, a little rough; *Saturn*; and *Mr. T. Graham*. Edward Shenton, Esq., was third; and Messrs. Dobson & Sons fourth.

It was too early in the season for seedling flowers. The only noticeable one was a new bedding Geranium, for which an extra prize was awarded. It was the same one which had received a first-class certificate from the Floral Committee, and is called *Prince of Hesse*, and was raised by Mr. Ingram, of the Royal Gardens, Frogmore. It is of the rosy salmon class, somewhat after the style of Kingsbury Pet, a profuse bloomer, with dark horseshoe foliage and is likely to be an acquisition.—D., Deal.

NEW BOOK.

THE MINIATURE FRUIT GARDEN.*—In this, the tenth edition of Mr. Rivers' excellent work on the garden culture of fruit trees (for that is what it in reality is) we have an evidence that the cultivation of fruit trees is still in the ascendant, and that the old-fashioned practice of planting tall wide-spreading orchard trees in gardens is rapidly on the wane. Among the additions and improvements in this over former editions we observe corrected lists of the selected varieties, particularly among the Plums, into which several fine and valuable sorts are introduced. Another important feature is the *groundinery*, an improved form of the curate's vinery of former editions. In speaking of these Mr. Rivers says:—

"In gardens where these glazed ridge-roofs are not wanted for Vines or fruit-tree culture, they will be found most useful. They may be placed on any warm border on the surface of the soil; and early Peas, French Beans, and many other early vegetables requiring protection from spring frosts, be grown under them with advantage. For the cultivation of early Strawberries they are invaluable, as they not only hasten the ripening period, but protect the fruit from heavy summer showers often so injurious to the crop, and also from birds. Strawberry plants to be cultivated in ground vinery No. 1 should be planted early in autumn in narrow beds of two or three rows, the plants close together in the rows, so as to take full advantage of the glass-covered space. If in two rows, they should be 9 inches apart; if in three rows, 6 inches apart. The latter distance will probably crowd the plants too much; but as the beds should be made every season on a fresh piece of rich soil, as much fruit as can possibly be grown in such a limited space must be the aim of the cultivator. In all cases they, the glazed ridge-roofs, should be placed on bricks, with spaces between them. Ventilation is then secured; and even Cauliflower-plants in winter will do well without the constant attention to "giving air," so necessary in the old garden-frame culture. In gardens that are confined and very warm, it may be necessary to have the ends not quite closed up, but a small opening left at the top, just under the ridge, to let out the heated air. My vineries stand in a very exposed place, and do not require it."

THE EXPERIMENTAL GARDEN IS SOLD.—Mr. Nightingale, of Kingston, sold this garden, the house, and twenty-three acres of land, at the auction mart in London, on the 16th of May, for £15,500. The alterations which were commenced in 1853, consequent on the move for an experimental garden, did not cost altogether over £500, but were acknowledged by good judges in the family to have doubled the value of the estate as early as 1858, and I have no doubt myself that a thousand such places might be met with within an hour of our great cities which require a fresh turn over, and would well pay for it.—D. BEATON.

* *The Miniature Fruit Garden, or the Culture of Pyramidal and Bush Fruit Trees, with Instructions for Root-pruning, &c., &c.* By Thomas Rivers. Tenth Edition. London: Longmans.

EFFECTS OF LAST WINTER ON PLANTS IN ENGLAND.

(Continued from page 136.)

I VENTURE to send you an account of the ravages made by the frost of last winter amongst my evergreens, &c.

Taxodium sempervirens.—Dead.

Deodaras, 12 feet high.—Dead.

Wellingtonia, 6 feet high.—Dead.

Younger plants have lost 1 foot of their leaders.

Evergreen Oaks, 60 years old.—All dead.

Deodara robusta.—Dead.

Thuja aurea.—Dead.

Pampas Grass.—Dead.

Magnolia on south wall.—Dead.

Araucaria imbricata.—Nearly killed.

Cryptomeria japonica.—Dead.

Thuja gigantea.—Much cut.

Aucuba japonica.—Dead; generally speaking, even the roots.

Hollies.—All leafless, many dead. Eight on the lawn measuring:—1. 2 feet 3 inches. 2. 4 feet 11 inches. 3. 5 feet 3 inches. 4. 2 feet 7 inches. 5. 4 feet 4 inches. 6. 4 feet. 7. 4 feet 10 inches. 8. 4 feet—I am afraid will lose all their lower branches.

The *Cedrus atlantica* and the Cedar of Lebanon have lost all their foliage, but are now breaking.

Rhododendrons.—Very much browned, and in many instances dead.

Yews and *Box*.—Ditto.

Privet.—Many hedges totally destroyed, others have lost plants here and there.

Ivy.—Leafless and in many instances dead.

Pinus insignis, *Fitzroya patagonica*, and *Libocedrus chilensis*.—Dead.

Even the common *Elder* is dead to the roots in many places; and in taking down some young *Oaks* I found several dead at the top. The two worst had 21 feet out of 60 feet, and 27 feet out of 58 feet dead. These trees were marked in the winter; so, doubtless, I shall find many more in a similar way when they are examined later in the year. At present it is quite impossible to say which *Oak* is alive. There is scarcely one that has not lost all the ends of its branches, so that they all look truly wretched. As for Laurels, I consider them a thing of the past.—W. B., *Stradsett Hall, Downham Market, Norfolk*.

WE are on a considerable elevation bordering on the south coast. The frost here was very intense, and has acted with unusual severity on many things. Common Laurels, Portugal Laurels, and *Laurustinuses* of many years standing, and considered able to bear any amount of frost, have been seriously injured, while some things of whose capability of standing a severe frost we have always been doubtful, remain untouched. These include *Aucuba japonica*, *Arbor Vitæ*, *Thujas*, *Bays*, &c.

The damage to newly-planted shrubs has been very serious. Relative to *Roses* we have a sad tale to tell. Not one of the Tea-scented kinds remains, and the Hybrid Perpetuals are but little better. Some of the more hardy sorts remain only to remind us that their time, too, with us is short indeed.

On some wall trees newly planted just prior to the frost I had bestowed an unusual amount of care, but to no purpose. Its effects on them have been sad in the extreme: many of their shoots were so injured I was compelled to cut them close in. Where that was the case I cut the whole of them close back.

I believe the whole county of Sussex has felt the frost's effects equally severely, our neighbouring nurseries included. Of young fast-growing stock many thousands have, ere this, been committed to the flames, and valuable stock too. So direly has it visited one nursery of about sixty acres, that although in the beginning of last December I should have had little difficulty in getting a good cartload of good stout young *Bays*, yet, on paying another visit in the month of March, not one plant could be found untouched by frost.—JAMES C. CLARKE, *Wakehurst*.

SALE OF ORCHIDS.—At the sale of Dr. Butler's excellent collection of Orchids, at Woolwich, on the 15th inst., Mr. Stevens, the auctioneer, realised for them very high prices. There were three hundred lots, and the gross amount of the sale was upwards of £1500. The following are some of the chief prices given and the names of the buyers:—*Ærides crispum* (Wilkinson),

£9; *Saccolabium Blumei majus* (Warner), £14 10s.; *Saccolabium guttatum* (Veitch), £52. Two other specimens of the same sold respectively to Mr. Bassett and Mr. Day for £32 and £36. *Saccolabium ampullaceum* (Day), £21; *Vanda teres* (Turner), £16 10s.; *Erises Lindleyana* (Binns), £15; *Anguloa Clowesii* (Wilkinson), £13; *Phalenopsis amabilis* (Day), £14; *Cypripedium hirsutissimum* (Backhouse), £6 15s.; *Vanda insignis* (McMorland), £15; *Cattleya Mossiae aurantiaca* (McMorland), £18; *Erises Schrederii* (Williams), £21; *Saccolabium guttatum giganteum* (Day), £46; *Saccolabium præmorsum recurvum* (Veitch), £23; *Saccolabium curvifolium* (Day), £36, &c.

CONIFEROUS TREES AND SHRUBS:

WHICH TO REJECT AND WHICH TO PLANT.

FROM the experience gained in the winters of 1859 and 1860 we have now some guide as to the kinds of Coniferous trees and shrubs that should not be planted in the northern, midland, and eastern districts of England, where permanent beauty in trees and shrubs is desired. I will first give a list of those to be rejected.

1. *Araucaria imbricata*.—On dry hills this may be planted; but in low moist valleys it cannot be depended upon. The other species of this fine genus are all notoriously tender, and only fit for house culture. This is, however, no reason why they should not be cultivated; for, in the course of time, large houses, like orchard-houses without artificial heat, will be erected in such groves of the tender and half-hardy Conifers will be cultivated. As places of re-ort in autumn, winter, and spring, such houses would be full of interest.

2. Our next family of tender Conifers is—*Arthrotaxus*, all the species.

3. *Callitris*.

4. *Cunninghamia sinensis*, *alias* *Araucaria lanceolata*.

5. *Cupressus* (the Cypresses).—These, with the exception of *C. Lawsoniana* and *C. nuthansis*, *alias* *Thuja borealis*, have all given way in the above districts, with the exception of some places favoured by soil and site.

6. *Fitzroya patagonica*.

7. *Libocedrus chilensis* and *Doniana*.

8. *Saxe-Gotha conspicua*.

9. *Sequoia sempervirens*.

10. All the Mexican Pines, and also *Pinus insignis*, *P. radiata*, *P. brutia*, *P. halepensis*, *P. pinea*, *P. australis*, *alias* *P. palustris*, and *P. macrocarpa*.

I do not mention the well-known tender species, such as *P. longifolia* and *P. sinensis*. The list of Mexican Pines is a long one: I refer your readers to Gordon's "Pinetum," in which a great number are described, most of them remarkable for the great beauty of their foliage, and quite worthy of being planted in a large and lofty Coniferous-tree-house.

11. The species of *Podocarpus* are nearly all quite tender. The only one that is hardy and which seems likely to form a small yew-like tree is *P. japonica*, known pretty well as *Taxus japonica*; *P. andina*, and *P. nubigena*, said to be hardy, grow very slowly, and have not survived the past winter.

The Coniferous trees and shrubs that may be planted with safety in the districts I have mentioned are the following:—I have given a few exceptions in some genera, which I think quite necessary, as they have proved quite the reverse of hardy—a term so often misapplied.

All the species and varieties of *Abies* or Spruce Firs, except *A. morinda*, which is so often injured by spring frosts. The Chinese or Eastern Arbor Vites (*Biotas*) have proved remarkably hardy in dry, hilly places in the above districts, except *B. meldonis*, which is a worthless plant, and *B. freneloides*.

The Cedars *atlantica* and *libani* may be reckoned perfectly hardy; but *C. deodara* and all its varieties have suffered to a great extent the past winter, many large trees and nearly all young trees having been totally killed; still it is such a beautiful tree while young that we must not cease to plant it. The White Cedars (*Chamaecyparis*), have stood unscathed, except *C. thurifera*, which need not again be planted.

The *Cryptomerias* although browned by the winter are not killed. They are in most places ugly trees, and grow badly in chalky soils. The irony loams of the Sussex hills seem to suit them well; but they require the fierce sun of Japan to give them full vigour. I fear we shall never see any of them approaching the altitude of those grand forests of Japan which we read of in old Thunberg and more modern authorities.

The Junipers are among the hardiest of Conifers, a few among them are graceful ornamental trees and shrubs. The following kinds must no longer be reckoned hardy:—*Juniperus Bedfordiana*, *J. gossainthaina*, *J. macrocarpa*, *J. oxycedrus*, and *J. phoenicea*.

The Silver Firs (*Piceas*), are among the hardiest and most noble of our Conifers; nearly all of the species may be planted with safety. I must, however, except *P. pindrow* and *P. Webbiana*, which are almost invariably injured by spring frosts. *P. cephalonica* is nearly equally liable to injury from the same cause; *P. religiosa* *alias* *Abies religiosa*, is quite tender.

The pretty little *Retinosporas* are perfectly hardy, although they turn to a reddish-brown in winter, as if they suffered from frost. *R. ericoides* is well known as *Cupressus ericoides*.

Of the numerous varieties of Yew (I am inclined to believe there is but one species in cultivation—viz., the common Yew), not one is in the least tender. Some of these are more curious than ornamental, such are—*Taxus adpressa*, *T. canadensis*, *T. Devastoni* (a Weeping Yew), *T. Jacksoni* (another Weeping Yew). The Yellow-berried Yew, and *T. baccata horizontalis*. The variegated Yews which form such glowing pictures at Elverton are, in the eastern counties, in most places very ugly, their rich golden colour turning into a dirty white, as if the plants were diseased. This occurs not only in light soils, but in those that are deep, tenacious, and rich. All the species of *Cephalotaxus* so yew-like in their appearance, are perfectly hardy and bid fair to be very ornamental evergreen shrubs.

The western or American Arbor Vite (*Thuja*) are now a fine group of Conifers—one of the finest. All are perfectly hardy, and two species bid fair to rival *Wellingtonia* in interest. These fine trees are *T. gigantea*, which, unlike our old brown species, retains its bright green colour all through the winter; and *T. Lobbii* or *T. Menziesii*—not so gigantic in its growth as the preceding, but a beautiful evergreen tree. Its foliage is of a darker green than *T. gigantea*, and much like that of *Cupressus Lawsoniana*.

The family of *Thujaopsis*, or *Thuiopsis*, so nearly related to the western Arbor Vites as not to be distinguished from them by a casual observer, is now reduced to one solitary member—*T. dolabrata*, a Japan tree of great beauty, and likely to grow pretty well in this country, not appearing to require the forcing climate that some Japanese trees and shrubs look for. The popular tree now well known as *Thuiopsis borealis* has been looked at by botanists, who seem always to possess a forty-horse steam power of vision, and found to be a Cypress. It will remain a Cypress till some clever man with a sixty-horse power of sight finds that it is neither a Cypress nor a *Thuiopsis*.

Among Coniferous trees and shrubs that may be planted in all soils and sites, with not only safety but with a certain prospect of gratification in seeing it grow well in our summer weather, whether hot and dry or cool and cloudy, and looking fresh and green all winter even in severe weather, is the *Mammotree*—our *Wellingtonia*, the *Washingtonia* of the Americans. Our great great grandchildren may live to see it attain a height of 150 feet or 200 feet in this country; and middle-aged gardeners may, perhaps, regret that they cannot keep possession of their tenements of clay till that time. For my part I am quite satisfied with the tree as it is; for while young and feathered to the ground with its graceful radiating branches it is most beautiful. As it increases in age it will doubtless lose its lower tiers of branches and become mop-headed, like the figures given of the large trees which still exist in California. I have, therefore, no wish to see it past its beauty; and all old planters will, I trust, go with me.

I have in the above rough sketch endeavoured to show what Coniferous trees and shrubs we ought to reject and what to plant in the colder parts of England. Much more remains to be done. Some educated nurseryman or gardener with a thorough practical knowledge must one day give the public more information on this subject. A catalogue entitled, "Conifers Suitable to the Climate of Great Britain," is far too vague. We require—1st, a list of the interesting yet tender species and varieties that can only be planted in the soft, mild climate of the west of England, the south of Ireland, and in Jersey and Guernsey; 2nd, a list of such as may be planted in the districts I have named at the head of this paper, describing the soils and geological formations in which and on which they grow most vigorously.—SENEX.

FLOWER MARKET.—A new flower market is just opened in the noble curvilinear-roofed Floral Hall, adjoining Covent Garden

Theatre. Messrs. Milne, of Wandsworth; Mr. Standish, of Bagshot; and Mr. Fergusson, of Stowe, have collections of plants there, varying in prices from 6d. to many shillings, all in pots. Messrs. Negretti and Zambra have a stand of horticultural implements. There are various stands for the sale of garden-pots, vases, and baskets; and Mrs. Stothard has a stall for her beautiful artificial flowers made of paper.

A CHAPTER ON HEATING.

HOP-KILNS, HOT WATER, FLUES, AND POLMAISE.

It is not surprising that after an unusually severe frost the subject of heating garden structures should occupy a considerable share of attention in gardening periodicals; for any imperfection in the existing means is sure to be noticed as well as the more successful modes. And every one will admit the winter just passed to have been a trying one, and any scheme that has satisfactorily passed such an ordeal may be justly regarded as a meritorious one; and it is possible we may have several new schemes for hothouse heating offered to us with the warrant that they have stood the test of the past winter—and this is no mean qualification to found their claim upon.

I am far from certain that our very best modes are not exceedingly wasteful, not even exempting the best-contrived hot-water apparatus, or the recently-revived system of heating by hot air, called again into notice by Mr. Beaton and Mr. Kidd, which, doubtless, is a great improvement on previously existing means of heating in that way; but which is, doubtless, far short of what one day will be effected by the united exertions of those who may give the consumption of fuel and the heat it emits their close attention. In saying this much I by no means deprecate many of the useful plans now adopted; but I do not think any of them give all their warmth to the objects requiring it.

Some years ago I was much struck with a remark in a philosophical work of high standing, which was this: "The ascent of Mont Blanc was a laborious undertaking for an able-bodied man for two days, yet the combustion of 2 lbs. of coal ought to place him on the summit." This astounding assertion might have been questioned had it been made by a less eminent authority than Sir J. Herschel, for it was in one of his works that I read it; and although I do not remember his entering into any particulars of the natural or artificial powers just then compared, I have no doubt but the influence—the burning of this coal—exercised as much force over the external air as was equivalent to the raising of a human body the many thousand feet spoken of.

Now, this may appear to have little relationship with hothouse heating; but it may have, if the waste of coal be so great as the author quoted makes it to be. What improvements may not yet be expected? But let us turn to other subjects bearing still more directly on the matter.

The economy of heat has for many years been a source of study with those who have had the warming of buildings, for which fire heat, in some shape or other, is required; as, for instance, maltings, hop-kilns, laundries, workshops, churches, and public rooms, and the various classes of garden structures, which, for distinction, we may call hothouses. To this list others may be added; but enough have been enumerated to prove that attention has been directed this way.

Of the first-named of these (maltings) I have but little knowledge; neither is fire so much an accessory as in the hop-kiln. The due administration of heat being an important matter; and as several modes have been adopted, one of which so closely resembles that which has so recently attracted attention as a modification of Polmaise, that I make no apology for saying a few words on the hop-drying system as practised in this neighbourhood, where that article forms the most important of all crops, and its preparation for use is, of course, an equally important consideration.

I believe that our important crops are all perfected, or, I should say, harvested, in the open air, except in very bad seasons. But this is not the case with the hop; for, gathered in October, the sun at this period, even in the finest of all seasons, is not sufficient to dry up the superfluous moisture by which the article is charged, and it is more often wet than dry at that time; consequently fire heat has to be resorted to. And though there are many modes of applying it, there is but little difference in the kilns, which are generally circular brick buildings, of an inside diameter of from 10 feet to 18 feet, the sides being from

12 feet to 18 feet high, with a long conical roof, and an opening from 2 feet to 3 feet in diameter at the top. This is protected from rain by a cowl which turns with the wind. I may add that the floor on which the green and wet hops are laid is 2 feet or 3 feet below the eaves, and from 9 feet to 15 feet or more from the ground. The hop-drying floor is constructed of rafters laid about 2 inches apart, and over them a hair cloth is fixed. The timber used is usually poplar, which is the best to resist fire, and the hair cloth is also less liable to accident that way than anything else, and at the same time admitting the heat to pass freely through it and amongst the hops lying on it.

Now, from the under side of this floor to the ground level there is often a clear space of from 9 feet to 15 feet, and which has to be heated for the purpose of drying the green and damp load above, which is often laid on nearly a foot thick, and must be dried in ten or eleven hours; two such loadings being always dried every twenty-four hours, a rapid fire heat is therefore required. One of the modes adopted having so strong a resemblance to Polmaise, I cannot do otherwise than describe it. At the bottom of one side of the kiln in question a firehole is made, and a fireplace, similar to one that might be underneath a saddle boiler, is placed; but instead of the boiler a large cast-iron box like a trough is turned upside down over the fire, a square opening at the side opposite to the fire being made in one side of this box to allow the smoke entering a flue; and there is often a piece cut away in the front side of this box that is over the fire to allow room to feed the fire. The flue from this fire goes round the kiln, but does not join the outside wall, and the flue is sometimes raised on pillars also, so that all sides of it may communicate heat to the space requiring it, a chimney eventually carrying it out at some place where it unites with other buildings. Dampers in the flue regulate the draught, and openings in the outside wall with sliding shutters in front of them regulate the admission of external air, and the fire, being as described, inside the room requiring heating, we have as near as possible the mode of heating described and discussed with such a diversity of opinions in the gardening press about a dozen or more years ago as Polmaise; only in the case here mentioned the air to be heated is drawn from the open atmosphere, and is not worked in the rotary motion which baffled so many of the advocates for Polmaise.

Now, the flues in this hop-kiln were generally made of the best material, and when once got into working order were kept actively at work for the season, and appear to be constructed on a principle likely to economise heat, yet, it was found not to be so, and this class of hop-kilns is now almost obsolete; and although, as I have before said, it embraces almost all the points of Polmaise, it is more than fifty years since it was generally discarded. How long it is since it was introduced I leave for others to determine. Suffice it to say that its only claim to notice now is its adaptability to all kinds of fuel, which is not the case with the modes of heating now more generally in use, which, though hardly applicable to the general purposes of hothouse heating, may nevertheless be described here.

Instead of the covered-in fire before alluded to, an open one on bars and a little brickwork is fixed in the centre of the kiln; and immediately over this, but perhaps 6 feet from it, and 3 feet or 4 feet from the drying-floor, is suspended in chains a piece of plate-iron 4 feet or 5 feet square, and, being hung flatways, prevents the direct heat of the fire scorching the centre of the drying-floor immediately over it. This fire, however, is composed of charcoal, coke, and Welsh coal; and being open as stated, its action is very powerful on the floor above; and it is required so to be, as the thermometer is often kept at 130°. The wonder a stranger evinces is that the timbers composing the floor do not ignite; but poplar will bear a great deal of baking, and hair cloth still more so: nevertheless, fires do occasionally occur. It is right also to add that outside openings admit air to fires of this class also; and a recent patentee has surrounded his fire with pipes, one end opening into the fire, and the other to the open air—the pipes, of course, inclining from the fire outwards. Others, instead of having the iron plate hung as described above as a safeguard, have a number of cast-iron pipes crossing each other just over the fire, so that the fire heats the ends that are over it; and the air rushing out is also heated and carried upwards, its place being supplied by the air entering at the other end, which is outside. Many other modifications of these plans are in use, which might be profitably studied by those having the heating of hothouses in view—not that the open charcoal and coke fire here spoken of is eligible

for plants generally; but the heating here given to air, and the other principle on which its working depends, offer many hints to those inclined to turn them to account.

The above digression is given with a view to show that heating by warm air has been practised many years in some form or other; and some churches and public buildings are, I believe, heated on that principle; but by far the greatest number of workshops and buildings of a small kind are heated by an Arnott's stove, modified more or less to suit the circumstances of the place, and I must confess that no description of heating that I am acquainted with gives off so much warmth in proportion to the fuel used as a well-constructed Arnott's stove. An ordinary laundry stove I conceive to be of this class, and nothing can so quickly raise the temperature of a room as this does; and if some skilful hand could divest it of that unpleasant vaporous smell, it might be worked usefully in heating our garden structures.

It is not my purpose to enter into the nature of the gases generated by a stove of this kind; but every gardener knows, by a single whiff, that it is unsuited to plant cultivation. To chemists we therefore say, Purify it, and you will confer a boon alike on the vegetable and animal creation. And those who live long enough may possibly see this done. And when this has been fairly set into working condition, I have no doubt but we shall be several stages nearer that summit of perfection which has been aimed at in so many things; for I cannot bring myself to the belief that heat communicated to one object, and that object having to impart it to a second one, and this in turn to a third, and so on until it reach the object wanting it—much of it is not lost. We all know the more garments we have on when the weather is cold the less likely is the cold to reach us; and heat that has to be transmitted through several inches of brickwork, and then to travel some distance along a flue, withdrawing portions of its heat all the way as it travels, cannot emerge from its orifice in other than a much wasted condition.

In making the above observations I by no means intend to disparage the many useful heating apparatuses now in use at various places. What I want to see is, a material brought into practical use that will withstand fire heat, and not give off those unpleasant vapours which an iron stove invariably does; for be it remembered, the material ought not to be thicker than the iron plates of the Arnott's stove. If we could accomplish this, I think much, if not all, of the waste heat bestowed on the fireplaces, flues, and chambers, would act directly on the hothouse; for the whole apparatus, if prepared in a neat and tasteful form, might be inside. An opening to feed it with fuel and clean out the ashes might be made from the outside; but this ought to be closed as far as possible against external air. I have often pictured to my mind a heating apparatus of this kind, but am unable to suggest a material to make it of. Iron, as stated above, is objectionable, and brick is too thick. I should think a fireplace or stove formed of the material of which crucibles are made would be sure to stand heat well, as they are often heated to a white heat, and I have heard a manufacturer of cement articles assert, that cemented goods when well made will also stand an equal amount of heat. How far these two substances will not occasion those sulphurous or obnoxious gases which an iron stove is unable to avoid, I am unable to say. But the object is worth trying for, for with all our boasted skill it must be confessed we have made fewer improvements in heating garden structures than has been made in the construction of living-room stoves, kitchen ranges, and the like for the last thirty years, for I could point out a church that was heated by hot water in 1830, that has not been excelled yet, I believe, by anything of the kind since introduced. True, this useful agent has been brought into more general use, and made to ascend and descend where it was never expected to do; but it is an expensive affair, and now and then, like everything else, breaks down at the most unfortunate time for everything and everybody concerned.

A writer in THE COTTAGE GARDENER, at page 258, Vol. XXV., (Mr. Cullerne) expresses his unwillingness to advocate the Polmaise system because I had opposed. I am exceedingly sorry at this, for I by no means assume my opinion to be infallible, and I am equally pleased to find my views opposed by others, as well as confirmed by them, especially when a good sound reason is put forth for doing so, or, what is still better, a good bundle of facts. I think the most I said or intended to say against Polmaise was, that it was wasteful in fuel and liable to go wrong; but where it did work well, no mode of heating that I am acquainted with can equal it. A particular friend of mine had a spare pit heated

in this way; and as he was an enthusiast in that mode of heating, he used to point to the waving foliage of the plants when the house was closed as a proof of the circulation of air going on, and has told me he could cook an egg at one of the hot-air openings 30 feet or more from the fire, and certainly nothing could look better than the plants by which it was filled, for it was used for forcing. But I believe he had one or two sad misfortunes with it, and at all times it was extravagant in fuel, so large a portion of the heat escaping up the chimney. It is for this reason, and the consequent uncertainty of iron plates standing the fire, but cracking and filling the house with smoke, that I have advised the inexperienced to have nothing to do with it. Buried beneath a mass of brickwork it may, doubtless, be safe, but its heating powers must of necessity be much diminished unless urged on by extravagant firing.

Our able coadjutor, Mr. Fish, has very judiciously put before us boilers of various kinds, and alluded to their working qualities, and the many other points connected with hot-water heating, as well as that by flues; and there is one point in the latter mode which I wish to add to what he has said on this matter. It has always been my opinion that when a heat of only 40° or 45° is wanted, an expensive heating apparatus ought to be avoided, and to this end a good plain flue is often available. We have two span-roofed plant-houses here, each 36 feet long, intended for ordinary greenhouse and New Holland plants; these are heated by flues travelling round each house in the usual way, and ascending a chimney just over the fireplace. The two houses being in one length, the two fireplaces are just behind the wall at the partition; a front shelf about 3 feet broad, and a path about the same width traverse the entire length, the rest of the house being stage and platform. There is nothing particular in the heating, only that the flue which passes underneath the front shelf, and also that part which passes under the stage, is composed of cement pipes, 12 inches in diameter inside, and about an inch or rather more thick in substance; the ends being brickwork, more for the convenience of cleaning out at any time than anything else. These cement pipes are made in lengths of 30 inches or 3 feet, and have joints fitting into each other, and I can certify to their answering every purpose that can be wanted of them. The cost for Roman cemented ones being 1s. 2d. per foot, and for Portland, 1s. 10d., but either kind answers well. The flue rises and falls at the doorways where it crosses the pathway; but the rise and descent are both gradual, and not abrupt; they heat very well, and with less trouble than any hot-water apparatus we have. Observe, I do not mean to say that flues of this description ought to supersede hot water for regular and continued forcing; but for greenhouses, or structures requiring little more than the frost kept out, a flue is a much cheaper apparatus than hot water. All that is necessary to insure its action is to get the fireplace set low enough, and to have a few feet of upright chimney to end with, and let all the turns be easy bends; and when the flue must descend let the top do so as well as the other parts of the flue, for I believe the smoke travels along at the top, and ought not to meet with such an obstruction as a piece of perpendicular brickwork, or anything that way; and although all descriptions of brickwork give off unpleasant exhalations when first the fire is used, after being some time idle, this may in a great measure be guarded against by making the fire in the daytime, and opening the ventilators. Still, with even this drawback, I cannot bring myself to the belief that it is inferior to some of the toy kinds of hot water apparatuses, which are said to burn little fuel, and require little attention, but which are also very liable to very great uncertainties. A good useful hot-water apparatus of some size is another thing; but to make a fire in a place not larger than a man's hat, and expect that to keep burning many hours, is at variance with all my notions of utility. But I must conclude with again requesting our scientific friends in the fire-stove line to come forward and give us a helping hand; for so long as we waste so much heat on brickwork not wanting it, and in other ways allowing it to go up the chimney, so long is our heating-apparatus imperfect, and the sooner they are improved the better; for it must be confessed, nothing in the garden line, has made so little progress for thirty years or more.

J. ROSSON.

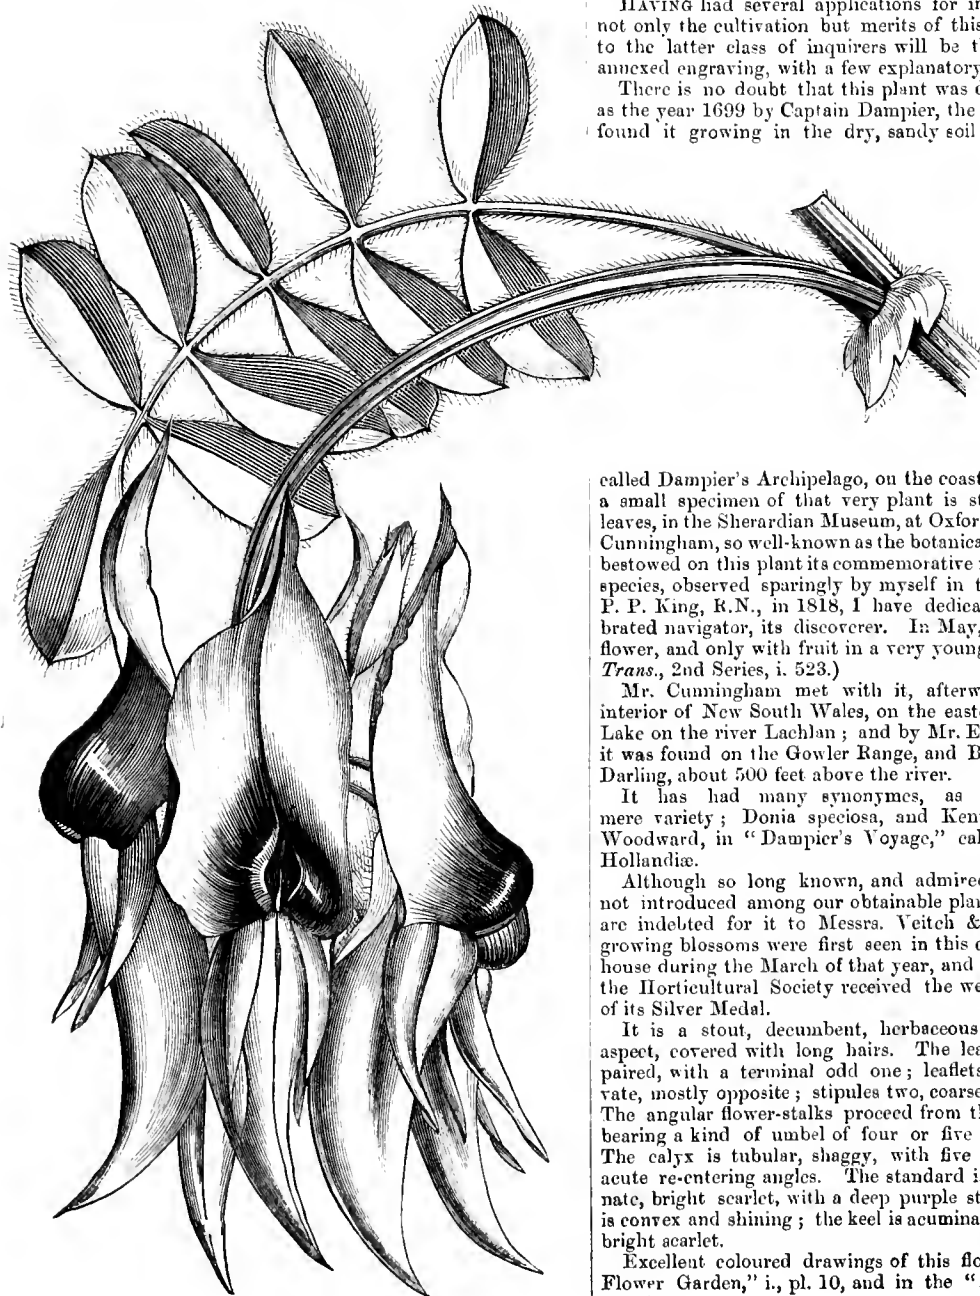

THE FAIRCHILD FLOWER SERMON.—The "Flower Sermon" was preached, as usual, on Whit-Tuesday evening, at St. James' Church, Aldgate, by the Rev. W. M. Whittemore, rector. The gaily-dressed young people, with their bouquets of flowers, made

the old church look quite attractive. The preacher's text was Psalm ciii. 15, and his topic "Wild Flowers." From these he drew various lessons of the Divine goodness; of the wonderful variety observable in the works of God; of the striking difference between the natural and the gracious states of the heart of man; and of the fading character of all earthly hopes. The Sunday Bible Classes, which are held at this church on Sunday afternoons, are open to all young ladies and gentlemen who are desirous to attend.—(*City Press*.)

CROSS-BREEDING SWEET PEAS.—I perceive Mr. Beaton, in *THE JOURNAL OF HORTICULTURE*, May 14, says he does not know of any one who has obtained a true cross in any of the Pea-flowering plants. I do not know if the following will interest him. About the year 1836 I crossed the Painted Lady and Purple or Puce Sweet Peas. I obtained very few seeds, and these the next season produced grizzled and striped blooms, being a mixture of the two colours. I do not know if Mr. Beaton will consider this a true cross.—B. P. BRENT.

CLIANTHUS DAMPIERI.

Nat. ord., Papilionaceæ. Linn. Diadelphia Decandria.

HAVING had several applications for information concerning not only the cultivation but merits of this plant, our best reply to the latter class of inquirers will be the publication of the annexed engraving, with a few explanatory notes.

There is no doubt that this plant was discovered as long ago as the year 1699 by Captain Dampier, the circumnavigator. He found it growing in the dry, sandy soil of one of the islands

called Dampier's Archipelago, on the coast of New Holland, and a small specimen of that very plant is still preserved, without leaves, in the Sherardian Museum, at Oxford. The late Mr. Allan Cunningham, so well-known as the botanical explorer of Australia, bestowed on this plant its commemorative name; he says, "This species, observed sparingly by myself in the voyage of Captain P. P. King, R.N., in 1818, I have dedicated to that very celebrated navigator, its discoverer. In May, 1818, it was found in flower, and only with fruit in a very young state."—(*Hort. Soc. Trans.*, 2nd Series, i. 523.)

Mr. Cunningham met with it, afterwards, in the western interior of New South Wales, on the eastern shore of Regent's Lake on the river Lachlan; and by Mr. Eyre and Captain Sturt, it was found on the Gowler Range, and Barrier Range, near the Darling, about 500 feet above the river.

It has had many synonyms, as *Clianthus Oxleyi*, a mere variety; *Donia speciosa*, and *Kennedyia speciosa*. Mr. Woodward, in "Dampier's Voyage," called it *Colutea Novæ-Hollandiæ*.

Although so long known, and admired by botanists, it was not introduced among our obtainable plants until 1850, and we are indebted for it to Messrs. Veitch & Sons. Its splendid-growing blossoms were first seen in this country in their greenhouse during the March of that year, and being exhibited before the Horticultural Society received the well-merited testimonial of its Silver Medal.

It is a stout, decumbent, herbaceous perennial, of a pale aspect, covered with long hairs. The leaves are pinnate, five-paired, with a terminal odd one; leaflets oblong, slightly obovate, mostly opposite; stipules two, coarsely toothed or slashed. The angular flower-stalks proceed from the axils of the leaves, bearing a kind of umbel of four or five most brilliant flowers. The calyx is tubular, shaggy, with five acuminate lobes, and acute re-entering angles. The standard is ovate-oblong, acuminate, bright scarlet, with a deep purple stain at the base, which is convex and shining; the keel is acuminate, and, like the wings, bright scarlet.

Excellent coloured drawings of this flower are in "Paxton's Flower Garden," i., pl. 10, and in the "Botanical Magazine," t. 5051.

WHAT CAUSES A DRAUGHT?

THE REASON THE KIDDEAN IS PREFERABLE TO THE POLMAISE SYSTEM OF HEATING.

Is there one person in ten who knows why there is a draught in a flue, and why raising the chimney increases the draught? I think not. And as I want to have a say about the Polmaise and Kiddean systems of heating, will you let me clear the way a little before I commence my discourse?

Let us suppose that we have a glass tube shaped like the letter U; that each leg is 6 inches long, and each aperture 1 square inch in area, and that the one leg is filled with water weighing (let us say) $2\frac{1}{2}$ ozs., and the other with a like bulk of oil weighing (we assume) $1\frac{1}{2}$ oz. Of course, one-half the oil will be driven out unless pressure is applied to restrain it; and if we put a valve on the oil aperture, that valve must be loaded with a weight of 1 oz., in order to prevent the oil from flowing.

Let us now imagine the bulk of water and of oil doubled by increasing the diameter of the tubes, then the pressure at the oil aperture will be 2 ozs.; but as the area of the aperture will be doubled also, the pressure will still be 1 oz. to the square inch. If, however, we double the bulk of water and oil by doubling the height of the tubes, still keeping the area of each aperture at 1 square inch, then the pressure at the oil orifice will be 2 ozs. to the square inch, and the oil, if it escapes, will escape with double the velocity which it would have done in either the first or second case above mentioned. Here, then, we have the first method of increasing the force of the outward current—viz., increasing the height of the differing columns.

Now, suppose that we retain the tubes at their original height of 6 inches, and for the oil weighing (by hypothesis) $1\frac{1}{2}$ oz., substitute a like bulk of ether weighing (by hypothesis) half an ounce only, then—although the height of the column remains the same—the ether will flow out with a force of 2 ozs. to the square inch. Here, then, is the second way of increasing the force of the outward current—viz., increasing the difference between the weights of the two columns, their height remaining unchanged.

Let us apply our example:—The water represents the column of cold air outside a flue, the oil the lighter warm air within it. And if we make that warm air into hot air, we shall produce an effect like that which followed when we changed the oil for ether.

Now, in Polmaise, the column of air between the heating surface and the point of exit is so short that in order to get a circulation of any considerable velocity we must resort to the second of the before-mentioned methods—namely, intense rarefaction of the air in the chamber, and this more especially if there is any adverse pressure to be overcome.

This intense rarefaction cannot be obtained without intense combustion in the furnace, and this intense combustion cannot be maintained without a great waste of heated air up the furnace chimney: therefore, the obtaining a circulation by means of undue rarefaction gives rise to the following evils:—1, Waste of fuel. 2, "Burning the air" by the excessively hot surface required. 3, Splitting the furnace and cracking the iron, from extreme expansion and contraction. These are, I think, the usual objections to Polmaise. Now, the Kiddean system obtains a circulation through the hot-air chamber by the first method which I have pointed out—viz., increasing the height of the column of warm air, and so gets rid of the three evils which arise from pursuing the second method, while all the good points of Polmaise are retained.

Had I to apply the Kiddean system on a level I should have an opening from the lowest point of my greenhouse into the bottom of the hot-air chambers, and the place for the escape of the hot air should be high up in the house; but I would not have a cold-air drain or hot-air flue, except so much of the latter as would be needful to give me the height of column I might require. The hot air is sure to find its way to the top of the house; why, then, not deliver it there where the loss of heat takes place? I would trust to the cold-air current to diffuse the heat through the house; for the air-chamber being at the lowest point of the house the coldest air for the time being would collect there, and so soon as that rushed in to be warmed, some not quite so cold would take its place, and so on. Of course I would have an opening from the air chamber to the outer air, so that I could ventilate at pleasure.

I firmly believe that a large house might be heated without flues, or drains, or any of the apparatus which our friends the hot-water folk will have it cost as much as pipes.—E. H., Bromsgrove.

WORK FOR THE WEEK.

KITCHEN GARDEN.

TRENCH up every spare piece of ground for the first plantation of winter stuff. The ground to be trenched 2 feet deep, and a good coat of manure to be dug in, when it will be ready for planting with Broccoli, Brussels Sprouts, &c. The Broccoli to be planted 2 feet apart each way. If fine heads are desired, a ring of hot lime to be placed around each plant of the Cabbage family to protect it from slugs. *Asparagus*, give the beds good soakings of liquid manure from the melon-ground cesspool, or from horse-droppings. Keep the surface of the beds free from weeds, and well pulverised by frequently hoeing between the rows. Where the supply from the established beds is abundant the weakest shoots may now be allowed to grow. *Cardoons*, sow a late full crop. Plant out the early crop; if they were sown in a seed-bed choose a rich piece of ground for the purpose. It will not be advisable to plant largely of the first crop, as it soon runs to seed. *Cauli-flowers*, liberal applications of liquid manure to be given to them. *Celery*, plant some of the most forward into trenches. Keep it well watered in dry weather. Continue to prick out from the seed-beds for late crops. *Cucumbers*, keep up the bottom heat of the principal beds if fine long fruit is desired. *Dwarf Kidney Beans*, earth up those that have been planted out, and sow again. *Endive*, make another small sowing. *Lettuce*, make a sowing of different sorts for successions. *Potatoes*, hoe between the rows, to loosen the earth and destroy weeds. *Sea-kale*, thin out the heads so as not to allow them to crowd each other, and water once or twice during the growing season with a weak solution of salt and water—viz., 2 ozs. of salt to a gallon of water. *Turnips*, make a good sowing for early autumn use. Thin out the advancing crops. *Vegetable Marrow*, plant out on a rich piece of ground where there is plenty of room for it to grow.

FLOWER GARDEN.

The directions given last week are still applicable to operations going on here. *Heliotropes*, *Ageratums*, and tender annuals may now be planted out with safety. As soon as the beds are all filled and finished off, plant out into the flower-borders some of the odds and cuds which were left reserving a few to receive high cultivation in order to fill up blanks either in the houses, beds, or borders. Attend to the sticking of Carnations and Pinks as they grow, it will greatly enhance their appearance when in bloom. Plant out Dahlias, mulching and watering the soil liberally in dry weather. Masses of American shrubs under or near large trees would be benefited by a top dressing of half rotten leaves or old tan, with a liberal supply of water in hot weather, to keep them cool, and to compensate in some measure for the exhaustion occasioned by the roots of the trees.

FRUIT GARDEN.

Keep an eye on the Gooseberry caterpillar, and let blooming Strawberries be well supplied with water. Where black fly has attacked Cherry and other wall trees give them thorough good washings with the engine: pure water to be used for the first time, which will partially destroy them. A good washing of soapuds and clear water to be applied by the same means, and on the following day another good washing to be given with clean water. The same practice to be persevered in until the pest is entirely removed.

GREENHOUSE AND CONSERVATORY.

When the cold pits and frames are cleared of the bedding stock they will be the most suitable places during the summer for the growth of many things for the autumn and winter decoration of the conservatory. It is not advisable to continue the stopping of the stronger shoots of *Epacris* after they have attained a fair blooming size as it eventually leads to the production only of weak, small shoots which cannot bring many flowers. When the plants are allowed to form moderately-strong shoots the flowers, from being produced at almost every leaf, grow in long spikes, and are then finer and more vigorous than under the opposite circumstances when the plants are continually topped, so that the shoots become small and weak. As the habit of these plants is to produce long shoots, they must be annually pruned into form, and even beyond this any luxuriant shoot that appears may be turned to account by the practice of stopping. The present is a good time to sow a supply of Chinese Primroses for the winter. Get them potted off early, and keep them shifted and growing in a cool frame where they can have plenty of air and some protection from heavy rains. Use a

light, rich, loamy compost; a cool temperature, with plenty of air, gives a high colour to the blooms. Repot Melocacti, Echinocacti, Mammillarias, &c., if necessary using good loam intermixed with charcoal broken to the size of nuts. Place them in a hotbed where the heat is gentle; give them a moderate share of fresh air, and a supply of clear, weak manure water once a-week. This treatment to be continued for a couple of months, when they may be removed to a greenhouse to ripen their wood, and afterwards to be set in a hot, dry place out of doors for a few weeks before housing. Pinch off the decaying blossoms of hybrid Rhododendrons, give them liquid manure, and, if wanted for early work, give them a warm place to force them slightly into wood.

W. KEANE.

DOINGS OF THE LAST WEEK.

WEATHER hot and scorching during the day, cold at night; nevertheless the ground is getting warm. Continued routine of work much the same as last week. Repotted Begonias, Gloxinias, Achimenes, and brought the latter from under the dense shade of Vines into a later house, where they have a little more light: cannot yet give them a better position. All plants in pots required a great deal of watering. Noticed for the first time a little red spider on two or three *Strawberry plants* on a lofty shelf in theinery; whipped them out at once, and will get forward ones from such places near the apex of the roof into a garden-frame as soon as possible, as that will give heat enough for forward ones if the weather keeps sunny. Have tried Sir Harry for forcing, we think, for the last time—the fruit, though large, being few in quantity. Ingram's Prince of Wales has done well; and Queens, of which I have gathered none, are swelling nicely. These two last and Keens' will be our main croppers next year, with a few of Black Prince for early ones. Strawberries out of doors have had the Dutch hoe run through the rows to prevent the stiff ground cracking; and in some instances have been stirred with a steel fork an inch deep or so, but not more. A gentleman told me the other day he had his all dug between, because he saw it recommended in some gardening book!! Oh, the poor roots! From the time of planting until they are dug down we should think it next to sacrilege to admit a spade among Strawberries. A few flowers have been blackened, but at present the bloom is extra in strength and profusion. The plants have already had a soaking of manure water, comfortably warm, and would rather like another dose, and must have it if the rain does not come soon in good earnest. Litter from the stable has had the dung shaken out of it pretty well, to be saved for Mushrooms; and the litter will be placed between the Strawberry-rows as soon as the ground has been well watered naturally or artificially. This litter will be washed clean before the Strawberries are ripe; but those extra fastidious should use a little clean well-thrashed straw at once. Many use short grass from the lawns, and almost anything is better than allowing the fruit to lie on the ground; but in wet seasons the grass is apt to be imbedded into the fruit, and in all seasons you are sure to have a rare crop of daisies and other weeds. All our trials of slates, tiles, &c., led us to the conclusion that the advantages they rendered were too problematical to recommend them for general use. In a small place, however, they certainly promote cleanliness, and in bright weather the fruit ripens sooner; but in very hot weather it is apt to be something like parboiled. Any contrivance, however, is better than letting the fruit lie on the ground. Where litter is inconvenient, little sticks, the diameter of the little finger and 18 inches long, stuck along each side of the rows 4 feet apart, and a small string run along from one to the other all round will keep the fruitstalks nicely up, and the plan looks very neat and the fruit very inviting. But perhaps it may be only a fancy of mine, but certainly I have thought that Strawberries, whether in pots, in houses, or in the open air, did not have such a good chance of swelling freely and to a large size as when the fruitstalk was allowed to hang down. The very weight of the fruit would thus bring more juices to sustain itself by the strain thus given.

Everything else, however, this last week has had to give way to preparations for bedding out in the flower garden. We seldom do much until the 20th. However, on the 18th we put a row of *Salvia fulgens* round some large beds of Hollyhocks and Pillar Roses, the Roses being all cut to the ground and many gone altogether. A band of *Coreopsis bicolor nana* was

placed round the *Salvias*, to be followed by *Asters*, there being a band of Musk next the outside. On Monday the 20th we commenced in earnest, chiefly with *Calceolarias* and *Scarlet Geraniums*. We pot no *Calceolarias* in general, nor *Ageratums*, and very few *Scarlet Geraniums*. Some of the latter did not lift so well as usual, owing to the material in which they were planted being too deep and light; but they will only flag a little for a few days, and most of them are standing as well as if they had come out of pots. And most things so planted, we are convinced, do better afterwards than plants from pots, unless there are the time and the care taken to break the balls and disentangle the roots, which would be a serious affair when thousands must be quickly disposed of. The bedding-out plan in intermediate beds, to grow and harden before final planting out, has another advantage—a greater number can be carried or wheeled to the ground in boxes or sieves, and then there are no pots to bring back. Some of the tenderer variegated *Geraniums* do not do so well when thus planted out and lifted; and in their case we find it best to pot singly in small pots, encourage growth until the pots are pretty well filled with roots, and then turn them out into intermediate-beds into rough soil and leaf mould, and to be protected as long as they need it. If the bottom ground is hard, these will do all the better. This saves almost all watering previously to planting, and the plants are nicely furnished with roots, which strike into the ground at once. Of course, growers for sale must, to a great extent, use pots.

As I find it impossible to do much in the way of changing the soil, I generally as much as possible change the cropping every year. This was easier to do in the old bedding system where great breadths were made of one colour; but it requires more trouble and consideration, since stripes, and dots, and crosses have become also a part of the fashion. Thanks to an esteemed coadjutor, I have hardly a thing to tell. If I have a regret at all, it is that in saying so much of the bedding, &c., he picked out so few faults. The sunk garden, which is not at all in unison with his artistic taste, remains as it was; but planted differently, and with slight bands round the beds, which will tend to make the grass paths look wider. Its very simplicity makes it, perhaps, easier planted than a more artistic design, such as I have no doubt our friend would soon place in such a good position for seeing the colours of the whole plot all at once. The designs of all the other borders are also altered. Whether improved or not is another question; but I fear that telling about all the little ous and ins about them would hardly be in unison with this gossiping article, though we can think of little else at present.

The weather being so uncertain, and some of the plants intended for groups being rather small, we have been forced to leave many designs unfinished, and even to pot some things, and give them a fortnight or three weeks' nursing. This is much better than running risks, though I find my handy labourers do not like it so well. The work seems to go on with more zest when they see it all and finish as they go; and when it is necessary to leave out tenderer plants the whole matter should be fully explained, as every man works better when he sees the object and design of his working. A bit of a rogue once told me that the hardest work and the greatest punishment he ever received was being compelled to carry stones from one heap to another and back again, to serve no object whatever, but to keep him on the trot. The treadmill was nothing to it if the mill was made to serve any purpose of utility. The same principle applies to all labour. It is better done, more cheerfully and zealously performed, when the worker sees the object of his work.

Among the things for which we must wait a week or two are *Perilla nankinensis* and *Cineraria maritima* seedlings. The *Perilla* may be strong enough by the end of the week, but the *Cineraria* will require the best part of a fortnight, being just potted singly in 60-pots from boxes, in which they were pricked out thickly from the seed-pan. I still like cuttings best, but the last winter killed most of the plants, though they had stood well previously out of doors until I wanted them: and therefore, fearing the cuttings would be deficient in quantity for spring propagation, I sent for a sixpenny packet of seed; and I think in a fortnight I shall have some five hundred nice little compact seedlings, 3 inches to 5 inches high, in fine order for turning out. The cuttings are already planted. A correspondent who lately made inquiries about these seedlings may, therefore, be confident of their answering; still I like cuttings by far the best.

One peculiarity I must just mention. Every plant has a little compost put round its roots, formed of equal parts of rough leaf mould roughly riddled through an inch sieve, sandy fresh loam, riddlings from the potting-bench, and the burnt earth and charred rubbish spoken of last week. This all mixed together is just nice as to dryness and nice and warm to put round the tender roots, and no check is felt from coming at once in contact with the cold ground. A friend who was pleased with the half-burned, half-charred heap thought plants could not have too much of a good thing, and used it too hot and too much by itself, and then wondered the plants did not get on nicely. He forgot that it was possible to surfeit plants, just as a man may eat too much beef or take too much wine.

One word more. In very sunny weather it is useful to shade the tenderer plants, that show the moving most, with a few small evergreen branches, such as laurel or any twig of deciduous trees if in leaf. If not securely put in the ground, however, the sweeping of these by winds will do much harm; and besides, there is the trouble of getting them, their unsightliness stuck over the place, and the bother of clearing them off again, and sweeping and picking up the leaves that drop from them. Unless in extreme cases and where a little protection may be needed, as in the case of *Heliotropes* turned out earlier, I find that the same object may be gained by sending a boy to syringe the tops several times during the day. Mere watering at the roots after being done sufficiently, will not by repetition, when not wanted, affect the flagging of the foliage; but the syringing will. When a large space has to be done a man takes a garden-engine, and by regulating the discharge into a mist, like dew more than anything else, the leaves are moistened and the ground partially, so that a humid atmosphere is kept around them and prevents them perspiring too freely. Thus used, a potful of water will do more good than a dozen applied either by spout, or rose, from a pail; and as for liking the work, there seems a sort of mesmeric attraction between all kinds of squirts and boys pretty well of all ages and sizes.—R. F.

APPROACHING FLOWER SHOWS.—We would draw attention to the very liberal prizes offered by the Belfast Botanic and Horticultural Company. We hear that it is likely to be a very superior exhibition. The Royal Agricultural Society of Ireland hold their meeting at Belfast during the same week. We are very pleased to find that at Liverpool and other large towns, induced by the example of Bloomsbury, shows strictly confined to plants grown in streets and alleys are being announced. On the 30th of July there is also a Flower and Allotment-holders' Show at Kingscliff, in the grounds of Archdeacon H. K. Bonney. The exhibitors are such as do not keep a gardener, cottagers, and children, all judiciously classed. Of all these we should like to have the reports.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

PLANTS FOR WET PEAT SOIL (*A Subscriber*).—Unless you mean such plants to be of no use or ornament, but only as botanical rarities, the peat earth from the fens of England, or the bogs of Ireland, or the moss hags of Scotland, will be of no use to you except as dressings to very light or very heavy land. *Drosera rotundifolia*, *Pinguicula vulgaris*, *Eriophorum polystachyon*, or Scottish Pampas Grass, and the *Rubus arcticus*, the wild Raspberry of Scotland, and the Scottish Cloudberry, the best native fruit of all the Highlands, are the only plants out of scores which grow on bogs and boggy peat that we could recommend for cultivation; but there are very few gardeners who could grow and fruit these plants for you anywhere.

MANURING VINES (*A Subscriber*).—If your Vines are vigorous, and, as you say, they are swelling off their fruit well, they will probably need little assistance by manure. If the Vines are rather weakly you may give them some liquid manure made of the pigeon's dung you mention. Take care to keep the roots well supplied with moisture, and warm by covering at night if cold, wet weather occurs, as they are planted outside.

JOB'S TEARS (*H. M.*).—The bead-like, flattened, opal-coated seed which you enclose, resembles a falling tear, and is produced by a plant known as "Job's Tears" as long since as the time of Gerard, who in 1596, cultivated it in his garden in Holborn, under that name. It is a species of grass called by botanists *Coix lacrymifera*, and you will find a drawing and description of it in the "Botanical Magazine," t. 2479. You must treat it like a tender annual, but may plant it out in a warm sheltered border in June.

PLUM GRAFTING (*T. C.*).—Early in March is the best time, or at such time as the swelling of the buds shows that the sap is in motion. The modes are precisely the same as for the Apple or Pear. Why not propagate by budding, which may be done in July and August? Your question about bees is answered in a communication from "A DEVONSHIRE BEE-KEEPER."

FLOWER GARDEN PLAN (*J. C. C. J.*).—You have made a very good disposition of the plants in all the parts of your flower garden, which is a lady's fan, with a run of the late Duchess of Bedford's Chain on each side of it, and an excellent adaptation of double ring-beds over the top of the fan for Humeas—a nice fancy pattern. The edging to 7 is superfluous, and unless there was room for a broad band of it—say 9 inches or 10 inches wide—it would not be in character. 3, 3, would be better without an edging, and yellow is out of all character to edge a white bed with. In 5, 5, let Pink Pet, which is a fifth or sixth-rate bedder, be discarded, and let the edging of *Tropaeolum elegans* run all over the bed, and you will never repent it, and watch that *Gazania splendens* does not run over and annihilate your beautiful white edging to it. *Rigens* is the only plant we would ever use to edge *Gazania splendens* with, and both open in the sun, and shut up their flowers in dull weather. We have them now both in bloom together, and the first sight of them paid for all the bother we had to keep them true.

MAKING CONCRETE WALKS (*J. R.*).—No drains are laid under a concrete walk—and to have drains and run any walks, unless in close-glazed pipes, is a wrong idea though still cheap. There is not one thoroughly good garden walk that I know of within fifty miles of London, and they are all too expensive. In large kitchen gardens, where deep drainage is required, the bottom of the walks is the best place to carry the pipes through, but then the pipes will be a yard at the least below the walk, and the damp from the drain will never affect the bed of gravel. The gravel is, therefore, as safe from damp as the joists under the drawing-room floor, as the gravel of all walks ought to be in such a climate as ours. Anybody who has ever assisted bricklayers or masons to put in concrete under foundations can be trusted to make concrete walks, and even be consulted on making them. A solid bottom is all the preparation required before putting in the concrete. I had such abundance of chalk that I often used it one-half, and one-half rough stones and gravel, for a bottom, and in twelve hours it was fit to wheel on. Then I had it slightly watered to receive a last coat of fine gravel for a surface. That coat was of mixed best gravel and finest powdery chalk—say one-third chalk, and the layer half an inch in thickness. But lime is better, and in many places much cheaper.—D. BEATON.

CAMELLIA LEAVES BLOTCHED (*A Cheshire Subscriber*).—These blotches are usually caused by strong sunshine falling on the leaves in a close, confined air. There is no doubt that Camellias which have been somewhat neglected, by having their roots at one time too dry and at another time too wet, are most liable to this disfigurement. The roots by such vicissitudes are deprived of the power of supplying the requisite amount of sap.

STALKS OF VINE LEAVES AND GRAPES DECAYING (*C.—X.*).—They are affected exactly the same as those sent to us by "G. F. D.," and "M. A. M." See what we said in reply to them last week, page 144. That the roots of your Vine are too cold is rendered certain by what you state relative to their being outside, and the soil and subsoil being clayey.

VARIOUS (*A Subscriber*).—For general purposes no Cucumber is better than the Lion House. Store Carrots in sand, having previously cut off a slice of the top of the roots so that they cannot sprout. It is impossible to answer so vague a question as "which is the best Melon?" Do you mean for early or late production, green-fleshed, or red-fleshed? We never recommend tradesmen. *The Cottage Gardeners' Dictionary* may be had free by post for sixty-four postage stamps previously sent.

SCALE INSECT ON COTONEASTER (*Egdon Rectory*).—The Cotonaster is miserably infested with a species of Coccus or Scale, the females of which are now nearly full grown, and will shortly give birth to myriads of young. The only plan which we can suggest at this period of the year is to loosen the branches and rub them along their back sides where the insects occur with a hard nail or toothbrush dipped in a creamy mixture of soft soap, flowers of sulphur, and water.

FLOWER-GARDEN PLAN (*Larix*).—Three very pretty rustic raised basket-like circles, with the top of each filled with Flower of the Day and Verbena André mixed, making the beds look as if planted with some reddish-purple variegated Geraniums. The next step-beds from these tops filled with two rows of Tom Thumb, and edged with Purple King Verbena; and at the bottom a row of *Calceolaria floribunda*, and outside it a row of *Lobelia speciosa*. This idea is good, the manner of planting is better, and a white Verbena where Purple King is, and a variegated something where *Lobelia speciosa* is proposed, would make it one of the best of that style that we have seen. Purple King between light scarlet and shining yellow would only look dull, and dark blue *Lobelia* is, or would be, overwhelmed by a light yellow.

GRUBS IN SOIL (*Grubber*).—Tiy watering with lime water. Thoroughly soak the ground with it. It will not injure the seedlings. A peck of fresh lime to thirty gallons of water is the right proportion.

PEACH LEAVES BLISTERED (*A Subscriber, Ballina*).—We do not know a Peach named the *Scarlet Admirable*. However, whatever Peach it may be, the leaves are blistered. This is a disease the cause of which is obscure, but we believe that it arises from the young wood being imperfectly ripened the previous year. This renders the shoots peculiarly liable to injury from spring frosts and sudden vicissitudes of temperature, which always are liable to injure the foliage. Why the other Peach trees are not similarly injured is inexplicable, unless we knew whether they are planted more shallow, or as less vigorous growers.

PAINTING GLASS TO AFFORD SHADE (*A. D.*).—Take a quart of jelly size, half a pint of water, a dram-glass or half a quart of turpentine, the same of linseed oil, and about as much whiting as a walnut nicely powdered, and put it all in a kettle over the fire until it is near boiling, stirring it well. Then when pretty hot, take it to the glass and draw it thinly and quickly over it with a brush. If you have a dry brush and follow after, dabbing with the point of the brush quickly, it will look neat, like rough ground glass.

HEATING AND ARRANGING A SMALL GREENHOUSE (*Notice*).—We have no faith in the safety of any stove without a chimney. See what a correspondent says about his stove enclosed in a corner of the greenhouse. A small double iron stove—that is, with the fire-box not touching the side, and a flat top for a vessel of water ought to heat your house sufficiently. See what Mr. Robson says to-day about Arnot's stoves. If you prefer hot water, a small brick stove with a boiler like that of Mr. Rivers' on the top of it, or

a boiler like that described by Mr. Al'en, would suit you; but we are convinced the best would be an iron stove, if you did not want much heat, and the small funnel could go through a square of glass in the roof. The house will hold more small plants by having a stage like steps, and individually they will have more room and light, just because your diagonal line is longer than the base. A flat table or shelf would be best for the front. No creeper would look more handsome than *Passiflora coerulea*. You could grow Cucumbers over the roof without fire heat after June, more especially if you obtained a good strong plant from a neighbour, but we would not advise such a proceeding if you value the plants on the stages beneath. A Vine would be every way better, and need no fire at night, when your plants did not need any, whilst it would not be so exposed to insects, nor be so troublesome to manage as the Cucumber. If anxious for Cucumbers, you can, however, manage them in such a place, and if you shut up the house pretty early in the afternoon, you may have splendid fruit hanging down from the end of June to the end of September. You would see much on Cucumbers in late Numbers.

GROWING ACHIMENES AND LILIUM LANCEFOLIUM (J. B. W.).—The Achimenes will begin to come now, it kept dampish, and will do very well in the greenhouse during the summer. As soon as the tubers push a few inches—say two—put them, four or six, in a six-inch pot, using sandy soil and leaf mould, and well-drained pots. Keep them at first in a close shaded part of the house. The *Lilium lancefolium* should be kept nearly dry in winter, after the stems die down; be watered as soon as the bulbs begin to move, and fresh dressed with rich compost. If the pots could be kept on the floor of a cellar, or any other damp place in winter, they would need no watering.

CULTURE OF THE GUAVA AND MUSA CAVENDISHII (Clericus).—The Guava is very accommodating, but of the three places mentioned, the vinery, where the heat does not fall below 40° to 45° in winter, would be the best, though it would fruit well in a Peach-house if the plant was kept warm enough in winter. It delights in rough light loam; and a good-sized plant can be grown in a large pot, or box. If the pot is small for the plant, frequent top-dressings and rich manure waterings should be given in summer. It will stand a little shade, but the more shade in summer and autumn the less fruit next year. In winter it needs little water; but it must not be parched. The *Musa Cavendishii* can be fruited in the smallest space, when a well-rooted sucker is planted in a bed, heated below at pleasure, with hot water, and plenty of light and heat and air are given. We recollect no other mode. Planted in a pot, much the same results would be obtained if the conditions as to light, &c., are supplied.

NAMES OF PLANTS (Wilfred).—1, *Luzula campestris*; 2, *Luzula pilosa*. (J. W. S.).—Of No. 1, your specimen is too imperfect for determination, the solitary flower stem being entirely without ovary. It looks as if it were an Irid, and is, perhaps, some species of *Sisyrinchium*; 2, is *Saxifraga sarmatensis*. (A. Subseriber).—1, *Pachysandra procumbens*; 2, *Oberis sempervirens*; 3, *Piblox subulata*; 4, *Ambretia purpurea*; 5, *Daphne coccineum*.

FLOWER SHOWS FOR 1861.

JUNE 5th and 6th. ROYAL HORTICULTURAL SOCIETY. (Plants and Fruit.) *Garden Superintendent*, G. Eyles.

JUNE 5th. PORTSEA ISLAND. Sec., H. Hollingsworth, Southsea.

JUNE 11th. ROYAL OXFORDSHIRE HORTICULTURAL SOCIETY. (Plants and Flowers.) Sec., W. R. Hobbs.

JUNE 12th and 13th. YORK. Sec., J. Wilson.

JUNE 19th and 20th. BRIGHTON AND SUSSEX FLORICULTURAL AND HORTICULTURAL SOCIETY. Sec., E. Carpenter.

JUNE 25th. ROMFORD. (Plants, Flowers, and Fruit.) Sec., Mr. Alfred Cooper, Romford.

JULY 3rd. PORTSEA ISLAND. Sec., H. Hollingsworth, Southsea.

JULY 6th. CRYSTAL PALACE. (Rose Show.) Sec., W. Houghton.

JULY 10th. ROYAL HORTICULTURAL SOCIETY. (Rose Show.) *Garden Superintendent*, G. Eyles.

JULY 18th. TOWCESTER FLORAL AND HORTICULTURAL SOCIETY. Sec., T. B. Rodhouse, Towcester.

JULY 18th. PRESCOT. Sec., J. Beesley.

AUGUST 9th. BELFAST. ROYAL BOTANIC AND HORTICULTURAL SOCIETY. (Plants, Fruits, and Vegetables.) Sec., George A. Carruthers.

AUGUST 14th. PORTSEA ISLAND. Sec., H. Hollingsworth, Southsea.

SEPTEMBER 4th and 5th. CRYSTAL PALACE. (Dahlias, Cut Flowers of other descriptions, and Fruit.) Sec., W. Houghton.

SEPTEMBER 11th. ROYAL HORTICULTURAL SOCIETY. (Dahlias and other Cut Flowers.) *Garden Superintendent*, G. Eyles.

SEPTEMBER 18th and 19th. BRIGHTON AND SUSSEX. Sec., E. CARPENTER.

NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums.) *Garden Superintendent*, G. Eyles.

NOVEMBER 12th and 13th. STOKE NEWINGTON CHRYSANTHEMUM SOCIETY. Sec., W. T. Howe.

NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show.) Sec., W. Houghton.

N.B.—Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.

POULTRY, BEE, AND HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

JUNE 4th, 5th, and 6th. BATH AND WEST OF ENGLAND. *Steward*, S. Pitman, Esq. Entries close May 4th.

JUNE 19th. THORNE. Sec., Mr. Joseph Richardson. Entries close June 12th.

JUNE 19th, 20th, and 21st. COALBROOKDALE. Secs., J. B. Cune, and Henry Boycroft, Coalbrookdale.

JUNE 25th. ESSEX. Sec., W. R. Eason, Slough House, Halstead, Essex.

JUNE 28th. DRIFFIELD. Sec., Mr. R. Davison. Entries close June 22nd.

JUNE 28th and 29th. TAUNTON. Sec., Mr. Charles Ballance. Entries close June 14th.

JULY 3rd, 4th, and 5th. BLACKPOOL AND WEST LANCASHIRE. Sec., Mr. E. Fowler, jun., Market Street, Blackpool. Entries close June 30th.

JULY 18th. PRESCOT. Sec., J. Beesley.

AUGUST 26th, 27th, 28th, and 29th. CRYSTAL PALACE SUMMER SHOW. Sec., W. Houghton.

SEPTEMBER 3rd. POCKLINGTON (Yorkshire). Sec., Mr. Thomas Graat. Entries close August 26th.

SEPTEMBER 24th. BRIDGNORTH. Sec., R. Taylor, Bridgnorth.

DECEMBER 2nd, 3rd, 4th, and 5th. BRAMINGHAM. Sec., Mr. J. B. Lythall, 14, Temple Street. Entries close November 1st.

DECEMBER 11th, 12th, 13th, and 14th. CRYSTAL PALACE WINTER SHOW. Sec., W. Houghton.

N.B.—Secretaries will oblige us by sending early copies of their lists.

MANAGEMENT OF EARLY CHICKENS.

EASTERLY winds cutting round corners, penetrating the best flannels, insinuating themselves into the most skilfully-contrived wraps, suggesting as the first morning duty an inspection of the registering thermometer, and a shudder as the fact was noted that, in the second week in May, 1861, there were 5° of frost, such things have suggested only the causes why poultry was dear and scarce. They have led to some little disquisition; but even that had assumed a character of discontent, and would have become ere long a record of disappointment.

The sunshine has altered all these things; and now—instead of looking at our chickens, and asking ourselves first, whether they were large enough for market; next, whether they would make the tempting prices of which we read—we now wonder whether they will grow enough to be summer winners. We try to recollect instances of unusual, almost incredible, progress, as our man said, "When once they'd started;" and at last we solace ourselves with the most unworthy comfort that we are as well off as our neighbours. If that idea be excusable in any instance it is in this, as it will be against more or less distant neighbours competition will take place.

We advise breeders to do with their chickens as head-masters of public schools are said to do with their scholars—to give all their care to those that will make a return for it, and by their attainments add to the reputation of the school and the renown of the master; while the others, less favoured by Nature, go on the even tenor of their way, consigned to the care of the writing-master. "I am sorry, Sir," says the disappointed parent, "but I do not think my son has made much progress since Christmas." "Indeed! Do you not think he writes a beautiful hand?" Paterfamilias withdraws. But the boy, the master is never tired of showing him off—scholarships, honours at College, and future pinnacles of greatness, all seem "looming in the future" for him.

The same thing is true of chickens: there are two distinct sets. The first will make you, in all probability, a brilliant return for any extra pains you may take—the best run, the best food, and the best attendance will be well bestowed, and pieces of plate or money prizes may be looked for through them; but hand over class 2 to the writing-master, let them go to market, or let them share with large asparagus, or early peas, the honour of dining some particular friend, or a warm maiden aunt, or a rich bachelor uncle—they will never make you a return in any other way. But it will be said, All the chickens cannot take prizes. Granted; but they can all sell.

It will, of course, be necessary to make provision for more than one exhibition; but even for one, that will be held in June, July, or August, it will be necessary to have several sets for selection, or to guard against accidents. The man who boasts he always hits the train to a society is sure to be too late on some very important occasion; and the man who attempts to show largely with a small stock will be sure to be disappointed when it will vex him most. If one out of three carefully-selected fowls should die, or go amiss, it will always happen the day of, or the day before, their departure for the great Show they were reserved for. Keep, then, a plentiful stock, it will enable you to choose easily; and, above all, if it is your intention to show in classes where feather is essential, be careful to choose birds that match. There are two reasons why the first weeding of the yard should take place now—the first is, that the refuse will make more money than they would if they were kept some weeks or months longer; and next, that by removing these there is more scope for the picked birds. We will treat of these next week.

PIGEONS' NESTS.—I have noticed a paragraph going the round of the papers, and which recently appeared in these columns, respecting the Sheffield Pigeons using horseshoe nails in forming their nests where straw was to be obtained. I do not see anything very remarkable in the fact, as Pigeons always prefer sticks and twigs to hay or straw for nest-building when they are readily procurable. I had a pair of Turtle Doves that picked

up in the garden the fine wires that had been used for labelling the dahlias, and lined their nest with them. I have also had Pigeons form their nest of hedge-clippings so full of thorns that the eggs would be sure to be broken or the young spiked.—
B. P. BRENT.

BEVERLEY AND EAST RIDING OF YORKSHIRE POULTRY EXHIBITION.

THIS Exhibition took place on the 22nd inst., and the following day. There were poultry amateurs who pre-supposed the entries this year would be somewhat limited, from the fact of its being held simultaneously with other meetings of like character. We are enabled unequivocally to state, however, that the collection of the present year even surpassed those that preceded it, proving beyond cavil that the interest publicly felt in the breeding and exhibition of choice poultry is not in any way decreased. Beverley, no doubt, possesses various attractions that conduce to the visits of sight-seers, independently of its annual Poultry Shows; but certain it is that numbers of individuals attending it from year to year, make choice of that particular season, that they may enjoy the privilege of viewing one of the most elaborately built minsters in the kingdom, combined with some of the most rural walks conceivable in the immediate outskirts, together with a stroll through as clean and well-ordered a town as we meet with in a lifetime, and that at one expense only. From these causes the amount of admission-money is considerable; whilst the gentlemen composing the Committee are equally notorious for their good management of the specimens confided to their care and courteous conduct to all comers. With such advantages it is not to be wondered at that the Beverley Show is always a good one.

As customary, *Spanish* headed the prize list; and although Mr. Fowler, of Aylesbury, secured the first position, he was very closely pressed by Dr. Pierson, of Bridlington, and Mr. Branford, of Sunderland. The quantity of first-rate *Spanish* hens exhibited was remarkable; but the class for *Single Spanish Cocks* was very indifferent. Mr. Berwick, of Helmsley, was lucky enough to obtain both the first and second prizes in the *Grey Dorking* class, and gain the premium for the best *Single Cock* of this variety, with specimens of the highest merit. It is useless to hope for a better show of *Cochins* than the one at Beverley, and by referring to the prize list it will be seen most of our principal breeders were in competition. As in former years, however, the *Game* classes were the most complete of any throughout the show-rooms; the Black-breasted Reds, Brown Reds, Duck-wings, and Black Game being all of the highest strains in the kingdom, and shown in the most perfect condition and plumage. It is an invidious task to particularise when all the classes were so unexceptionable; but certainly the winners of the two silver medals had to struggle for their success against heavy entries of the very best birds we ever saw together. The *Hamburgs* were both numerous and good. The *Polands*, though limited as to numbers, were also superior. The *Malays*, with the exception of the prize pens, were imperfect. The *Sultan Fowls*, *Brahmas*, and *Silkie*s, in the extra class were unexceptionable. The class "for any Farmyard Cross" drew together (as might be anticipated) one of the most singular medleys we ever met with; among them, however, were some extraordinarily useful fowls. Gold and Silver-laced *Bantams* competed in the same class, and we cannot help alluding, with pleasure, to the excellency of ground colour in the first-prize *Silvers*, the purity of which is always difficult to attain, and has now for some years back been almost extinct. The classes for "pairs of hens" mustered well, and formed one of the most interesting displays in the Exhibition.

The *Turkeys* and *Ducks* were very superior.

It was the general opinion of fanciers, that the *Pigeon* classes were far in advance of the collections brought together by the Beverley Committee on the three preceding occasions, although always considered one of its leading features.

Most unfortunately, the weather at the commencement of the Show was unfavourable; but we are informed that after a few hours there was a decided improvement.

The Judge appointed was Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, near Birmingham.

SPANISH.—First, J. K. Fowler, Aylesbury. Second, T. T. Pierson, M.D., Bridlington Quay. Third, R. S. Branford, Sunderland. Highly Commended, T. T. Pierson, M.D. G. Hoyle, Hessele. Commended, T. T. Pierson, M.D.

DORKINGS.—First and Second, H. W. B. Berwick Helmsley (Grey). Third, W. Dalby, Syston Hall, Grantham. Highly Commended, T. W. Hill, Hey-

wood, Lancashire. G. C. Whitwell, Kendal. W. Watson, Bishop Euton, Commened, F. Key, Beverley. Rev. T. F. Newton, Kirby-in-Cleveland.

COCHIN-CHINA (Buff, Lemon, and Cinnamon).—First, T. Stretch, Dootle Liverpool (Buff). Second, H. W. B. Berwick, Helmsley (Buff). Third, H. Tomlinson, Balsall Heath Road, Birmingham (Buff). Highly Commended, T. H. Barker, Hovingham (Buff). E. Smith, Middleton, Manchester (Buff). J. Cattell, Worcester Street, Birmingham (Buff). J. Mell, Hessele. Commended, W. Dawson, Hopton Mirfield. J. K. Fowler, Aylesbury (Buff). G. S. Simpson, Hunmanby.

COCHIN-CHINA (any other variety).—First, W. Dawson, Hopton Mirfield (White). Second, J. Shorthose, Newcastle (Partridge). Third, T. Stretch, Liverpool (Partridge). Commended, G. C. Peters, Birmingham (White). J. Bell, Thirsk (Partridge).

GAME (Black-breasted and other Reds).—First and Second, H. Adams Beverley. Third, W. Dawson, Selly Oak, Birmingham (Black Red). Highly Commended, H. M. Julian, Beverley. Capt. W. W. Hornby, Knowsley. H. Adams Beverley. Miss A. Stephenson, Beverley (Black Red). W. Raynor, Hunmanby (Black Red). G. Pease, Darlington (Black Red). H. M. Julian, Beverley (Black Red).

GAME (Duck wing and other Greys).—First, G. W. Langdale, Leckonfield. Second, R. Tate, Driffield. Third, H. Adams Beverley. Highly Commended, H. Adams. W. Dawson, Selly Oak.

GAME (any other variety).—First, W. Dawson, Selly Oak (Black). Second, R. Tate, Driffield (Blue). Third, H. Adams Beverley (Pied).

(The Silver Medal for the Pen in Classes 5, 6, 7, to Pen 51, Black-breasted Reds.)

HAMBURGH (Golden-pencilled).—First, W. Shipton, Moseley. Second, W. Grey, 83, Northgate, Darlington. Highly Commended, R. Hemingway, Red House Shelf, near Halifax. J. Robinson, Vale House, Garstang. J. Munn, Heath Hill, Stackstead. Commended, W. B. Key, Epworth. J. Munn.

HAMBURGH (Silver-pencilled).—First and Second, S. Shaw, Halifax. Highly Commended, J. Robinson, Vale House, Garstang. Commended, D. Barker, Hull.

HAMBURGH (Golden-spangled).—First, H. W. E. Berwick, Helmsley. Second, H. Carter, Uppertong, Holmbrith. Highly Commended, H. Adams Beverley. A. Hudson, Ousecliff, York. J. Robinson, Vale House, Garstang.

HAMBURGH (Silver-spangled).—First, J. Robinson, Vale House, Garstang. Second, W. Cannan, Bradford. Highly Commended, J. Dawson, Middleton, Manchester. S. Shaw, Halifax.

POLISH (Black with White Crests).—First, J. Dixon, Bradford. Second, D. Parker, Hull. Highly Commended, J. Dixon. Commended, G. Pease, Darlington.

POLISH (any other variety).—First and Second, J. Dixon, Bradford (Gold and Silver).

MALAYS.—First, C. Ballance, Taunton, Somersetshire. Second, R. Tate, Driffield.

ANY OTHER PURE OR DISTINCT BREED NOT PREVIOUSLY CLASSED.—First, W. Dawson, Hopton (Sultan Fowls). Second, J. K. Fowler, Aylesbury (Brahma Footral). Highly Commended, H. Beldon, Bradford (Silkies). Commended, R. Tate, Driffield (Brahma).

ANY FARMYARD CROSS.—First, Mrs. White, Thearne. Second, R. Robson, Ayrton. Third and Fourth, R. Tate, Driffield.

BANTAMS (Gold or Silver-laced).—First, S. Shaw, Halifax (Silver-laced). Second, T. W. Hill, Heywood (Silver-laced). Highly Commended, T. W. Hill, Heywood (Gold-laced). G. C. Peters, Birmingham (Gold-laced).

BANTAMS (Black or White).—First, J. W. George, Beeston Podge (Black). Second, G. C. Peters, Birmingham (Booted White). Highly Commended, D. Laybourn, jun., North Bar Street, Beverley (White).

BANTAMS (Game).—First, J. Shorthose, Newcastle. Second, R. Smiths, 19, Regent Street, Hull. Highly Commended, C. Ballance, Taunton (Duckwing). Capt. T. Percival, Whitby. Commended, H. Lyons, Beverley (Black Reds).

BEST SPANISH COCK.—Prize, T. T. Pierson, M.D., Bridlington Quay. Highly Commended, R. Tate, Driffield. D. Barker, Hull. Commended, J. K. Fowler, Aylesbury.

BEST DORKING COCK.—Prize, H. W. B. Berwick, Helmsley (Grey). Highly Commended, M. Kirkby, Driffield. Commended, T. H. Barker, Hovingham, Rev. J. F. Newton, Kirby-in-Cleveland (Grey).

BEST COCHIN-CHINA COCK.—Prize, R. Fielding, Middleton, Manchester. Commended, T. Boacher, 106, Bull Street, Birmingham.

BEST GAME COCK (Black-breasted and other Reds).—First, W. Hall, Keldgate, Beverley (Brown Red). Second, H. Adams, Beverley. Highly Commended, H. Adams, Beverley. W. Acklam, Etton Kennels (Black Red). G. West, Etton (Black Red). J. Hodgkinson, Hull (Brown Red). H. Adams, Beverley (Brown Red). R. Hemingway, Shelf, near Halifax (Black Red). Commended, Miss Griffin, Cherry Burton (Brown Red). J. Lowther, Beverley.

BEST GAME COCK (Duckwing and other Greys).—First, H. Adams, Beverley (Duckwing). Second, G. W. Langdale, Leckonfield (Duckwing). Highly Commended, H. Adams, Beverley (Duckwing). Commended, R. Blackburn, Goole (Duckwing). H. Adams, Beverley (Duckwing).

BEST GAME COCK (any other variety).—First, J. Woodhouse, Bampton (Black). Second, R. Tate, Driffield (Blossy-pencilled).

BEST HAMBURGH COCK (Gold or Silver-pencilled).—First, H. Adams, Beverley (Gold). Second, W. Cannan, Bradford (Silver).

BEST HAMBURGH COCK (Gold or Silver-spangled).—First, R. Tate, Driffield (Gold). Second, W. Cannan, Bradford.

BEST COCK (any Farmyard Cross).—First, R. Tate, Driffield. Second, W. Milner, Dunswell.

BEST TWO SPANISH HENS.—Prize, T. T. Pierson, M.D., Bridlington Quay. Highly Commended, R. S. Branford, Sunderland. T. T. Pierson, M.D., D. Barker, Hull.

BEST TWO DORKING HENS.—Prize, J. W. George, Beeston Podge (Coloured). Highly Commended, W. E. Eastern, Hull (Dark Grey). H. W. B. Berwick, Helmsley (Grey).

BEST TWO COCHIN-CHINA HENS.—Prize, J. Cattell, Birmingham. Highly

Commended, H. W. B. Berwick, Helmsley (Buffs). Commended, J. Mell, Hesse.

BEST TWO GAME HENS.—Prize, H. Adams, Beverley. Highly Commended, J. Woodhouse, jun., Bampton (Brown Reds). T. C. Trotter, Sutton, Hull. H. Adams, Beverley. R. Tate, Driffield. J. Pinder, South Duffield (Brown Reds).

BEST GOLD OR SILVER-LACED BANTAM COCK.—Prize, Master J. Crossland, jun., Wakefield (Silver). Commended, S. Shaw, Halifax (Gold).

BEST BLACK OR WHITE BANTAM COCK.—Prize, D. Laybourn, jun., Beverley (White). Highly Commended, Miss Foster, Molescroft, Beverley (White). Commended, E. Smith, Middleton (White).

BEST BANTAM COCK (any other variety).—Prize, W. G. Drewry, Market Place, Beverley (Black Red). Highly Commended, T. Rippon, Beverley (Black Red). J. Turner, Driffield (Black Red). W. W. Boulton, Beverley (Black Red). S. Shaw, Halifax.

BEST GANDER AND GOOSE.—First, R. Tate, Driffield. Second, A. Young, Driffield. Highly Commended, R. Tate.

BEST COCK AND HEN TURKEY.—First, J. Smith, Breeder's Hill, Lincolnshire. Second, R. Tate, Driffield. Highly Commended, R. Tate. R. Stephenson, Hull Bridge.

GUINEA FOWLS.—First, H. Mirkin, Driffield. Second, S. Shaw, Halifax. Commended, R. Tate, Driffield.

DUCKS (Aylesbury).—First, J. K. Fowler, Aylesbury. Second, R. Tate, Driffield.

DUCKS (Rouen or Rhone).—First and Second, T. H. Barker, Hovingham.

DUCKS (any other variety).—First, G. S. Sainsbury, Rowde, Devizes (Black East Indian). Second, J. Dixon, Bradford (Grey Call). Third, Mrs. F. Lawton, Theaine (Cross-bred). Highly Commended, Miss A. Straker, Horsea.

SWEEPSTAKES FOR GAME COCKS.—Silver Medal, Capt. W. W. Hornby, Knowley. Second and Fourth, H. Adams, Beverley. Third, R. Tate, Driffield. Highly Commended, H. M. Julian, Beverley (Red). Capt. W. W. Hornby.

SWEEPSTAKES FOR GAME BANTAM COCKS.—First, R. Hawkeley, Southwell. Second, R. Tate, Driffield. Third, J. Camm, Farnfield.

SPECIAL PRIZE.—A Silver Medal, value £1 1s., given by the Poultry Fanciers of Beverley, for the most perfect Pen of Poultry exhibited, was awarded (Classes 5, 6, and 7 being excluded from competition by the rules of the Society) to Capt. Hornby's Single Game Cock, the winner, also, of the general sweepstakes.

PIGEONS.

CARRIERS (Black).—First, W. Waton, Toll Gavel, Beverley. Second, J. Shorthose, Newcastle. Third, G. Robson, Saville Street, Hull.

CARRIERS (any other variety).—First, G. Robson, Hull (Dunn). Second, Mrs. E. Ellington, Woodmansey (Dunn). Third, H. Yardley, Birmingham. Highly Commended, H. Yardley. Commended, W. Cooper, Beverley (White).

POWTERS OR CROPPERS.—First, A. Cattle, York (Black). Second, S. Shaw, Stainland, near Halifax. Third, T. W. Lowson, Beverley (Red).

ALMOND TUMBLERS.—First, T. W. Lowson, Beverley. Second, T. Conndon, Sunderland. Third, Mr. William Watson, Beverley.

KITE TUMBLERS.—First, J. W. Edge, Ashton New Town. Second, J. Proctor, Keldgate, Beverley. Third, J. Bell, Beverley. Commended, R. Bell, Riding Fields, Beverley.

TUMBLERS (any other variety).—First, W. Statters, Tickton. Second, T. W. Edge, Ashton New Town. Third, Mrs. W. Watson, Beverley (Mottled). Highly Commended, H. Morris, Forest Hill, Kent.

BARS.—First, Mrs. E. Ellington, Woodmansey (Black). Second, D. Barker, Kingston-on-Hull. Third, T. H. Craigie, Woodlands, Chigwell. Commended, H. Yardley, Birmingham.

JACOBINS.—First, Miss L. Turner, St. John Street, Beverley (Yellow). Second, S. Shaw, Halifax. Third, Mrs. E. Ellington, Woodmansey (Yellow). Highly Commended, T. W. Lowson, Beverley. Commended, H. Morris, Forest Hill, Kent.

TRUMPETERS.—First, H. Key, Beverley (White). Second, S. Shaw, Halifax. Third, J. Shorthose, Newcastle. Highly Commended, J. Key, Beverley.

OWLS.—First, H. Morris, Forest Hill, Kent. Second, T. G. Gionton, Beverley Road, Hull. Third, Master H. Key, Beverley. Highly Commended, J. Bell, Beverley.

TURBITS.—First, J. W. Lowson, Beverley. Second, S. Shaw, Halifax. Third, H. Morris, Forest Hill, Kent. Highly Commended, J. W. Lowson, Beverley.

FANTAILS.—First, T. Ellington, Woodmansey. Second, T. Page, Eastgate, Beverley. Third, T. Rippon, Beverley (White). Highly Commended, Miss A. Key, Beverley. T. Rippon, Beverley (White). R. Lowson, Beverley. J. Y. Watson, Toll-gavel, Beverley (White).

ANY OTHER VARIETY.—First, Miss L. Turner, St. John's Street, Beverley (Spot). Second, Master T. Key, Beverley (Runts). Third, H. Morris, Forest Hill, Kent. Fourth, S. Shaw, Halifax.

SPECIAL PRIZE.—A Silver Medal, value £1 1s., given by the Pigeon Fanciers of Beverley, for the most perfect pen of Pigeons exhibited, was awarded to pen 475 (Spots), exhibited by Miss L. Turner, St. John's Street, Beverley.

CHESTERFIELD POULTRY EXHIBITION.

MAY 21ST, 22ND, AND 23RD.

It is now four years past since the institution of poultry shows at Chesterfield; and the fact is a most pleasing one, that the Meeting just closed, though inferior in the amount of numbers, was so good in quality that out of about 250 pens it was quite impossible to point out a really bad one.

In the *Spanish* classes were some of the best birds ever exhibited; Mr. Teebay, of Preston, taking both the first and second prizes, and Mr. Fowler, of Aylesbury, the third. The severity

of last winter, the coldness of the past spring, and perchance, too, the inroads of old age, begin to show perceptibly on the constitution of the first-prize cock in Mr. Teebay's pen; but even yet he is one of the most marvellous specimens of Spanish fowls to be met with; and the younger cock in the second-prize pen bids fair to be but slightly inferior after another moult, with careful management, as he will then have attained his prime. In *Grey Dorkings* the Show was excellent; and certainly it was an unusual feat for chickens of this year, so early in the season, to take precedence of matured birds. They well deserved it, as did also a cockerel shown in the class for *Single Dorking Cocks*. It will be noticed they were from the yard of the Rev. T. Baker, of Old Warden, Southill, Beds. They are indisputably the best-grown chickens we have seen this year, and, being entered at a moderate price, will probably change ownership. In *Cochins*, all the great guns of the day were in full play; Messrs. Stretch, Tomlinson, White, and Fowler taking positions in the order named. It would be very difficult to speak too highly of the *Game* classes. As a general rule the Brown Reds were in the highest condition of any, and certainly the "Sweepstake Game Cock" of that colour, belonging to Mr. Burgess, of Salop, will prove himself a troublesome rival on future occasions if kept up to the mark in which he is now exhibited. The *Hamburgs* and *Polands* were capital specimens; but one of the chief features of the Exhibition was the *Game Bantams*. Mr. Harvey Dutton Bayley's Black-breasted Reds were perfection, and with ease gave the go-by to competition. We cannot refrain from noticing the fact that both at Chesterfield and at Beverley Shows, though held simultaneously, the Rev. T. Baker, of Southill, Beds., took the prizes for *Single Dorking Cocks* with "chicks" of 1861—no mean achievement of his poultry-woman, considering they were exhibited against all ages. The *Single Game Cock* belonging to Mr. Gilbert Moss, of Liverpool, drew crowds of admirers; he was deserving the interest he created.

The competition in the *Pigeon* classes was remarkably severe, many of the Carriers were especially perfect.

The poultry was admirably arranged in a single tier, so that not the slightest plea could be made as to disadvantages of position, light, &c.; and the attention paid to the birds left nothing undone to secure them from injury of every kind.

Chesterfield could certainly boast this year of a most incongruous "extra class." In it could be seen a beautiful specimen of a perfectly white Sparrow; the eyes, as is usual in all Albinos, being of a bright red; the legs and feet being perfectly white. Even if at liberty it could not have possessed better plumage, and its whiteness was equal to that of writing-paper. It appears it was taken last spring from a nest in some ivy, containing another white nestling, at that time only partially feathered, and a third grey one. The old birds were of the natural feather of House Sparrows, without any variation of colour about their plumage in either of them. This makes the colour assumed by their offspring still more extraordinary. The Sparrow exhibited had been taught to turn a horizontal wheel with its feet, and caused no little amusement from the untiring dexterity with which it persisted in its endless employment. Although so purely white, it had been fed entirely on crumbs of bread and hempseed; whilst it is usually considered that hempseed tends to produce blackness of feather in all birds kept in confinement. Another oddity was included in this medley lot, and it was laughable to hear visitors inquiring of each other, "What's that?" "What is it?" "Well, I've heard of the Irish declaration of 'sucking pig' being the best of all poultry,' but this puts Paddy in the shade." It was an extremely large Badger, chained to a leather girth round its middle. The grizzly old gentleman lay constantly, according to general Badger-fashion, with his head turned under his body between his fore legs, as much as to say, "I'm brought here by compulsion of others, but even now it's my own fault if I'm looked at." Talking Jackdaws, &c., caused much mirth and hilarity to the Whitsuntide holiday visitors, and filled up as mixed-medley an assemblage as ever wound up the tail-end of a poultry exhibition.

Before concluding the notes of this Show, we cannot do better than mention a universal rule of the Chesterfield Committee that tends very much to its popularity, and would be a great amendment on the general usages at such meetings. Every exhibitor, without exception, receives at the hands of the Committee, not only a free admission ticket, but a catalogue and prize list gratis; the two latter forwarded immediately the premiums are awarded. Each one interested, therefore, gets the earliest intelligence of his eventual position as to success or disappointment.

Few places are so suitable for a poultry show as the Chesterfield Butter and Corn Markets. A flight of steps leads from the one to the other, and from this point a complete bird's-eye view of the whole is obtainable by every sight-seer.

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham, officiated as Judge.

SPANISH.—First and Second, R. Teebay, Fulwood, near Preston. Third, J. K. Fowler, Prebendal Farm, Aylesbury. Highly Commended, C. Brown, Carver Street, Sheffield. Lord E. Hill, Norwood Park, Southwell, Notts.

DORKINGS.—First, J. K. Fowler, Prebendal Farm, Aylesbury. Second, Mrs. W. Arkwright, Spendon House, Derby. Third, Rev. J. G. A. Baker, Old Warden, Southill, Beds. Highly Commended, T. W. Hill, Heywood, near Manchester.

COCHINS.—First, T. Stretch, Marsh Lane, Bootle, near Liverpool. Second, H. Tomlinson, Balsall Heath Road, Birmingham. Third, R. White, Clarke Street, Dronmhall Park, Sheffield. Highly Commended, J. K. Fowler, Prebendal Farm, Aylesbury.

GAME (Black or Brown Reds).—First, W. Jepson, Edensor, Bakewell. Second, G. C. Whitwell, Kendal. Third, S. Marsh, Ridgway, near Chesterfield. Highly Commended, B. Jarvis, Seacote Mill, near Mansfield. J. Jackson, Firbeck, Chesterfield. J. Lingard, Birmingham. G. Boot, Chesterfield. G. Hellewell, Sheffield. Commended, G. Turner, Chest vield.

GAME (Duckwing or any other Greys or Blues).—First, James Newton, Chesterfield. Second, G. Hellewell, Sheffield.

GAME (White or Piles).—First, G. Hellewell, Sheffield. Second, J. Camm, Farnsfield, Southwell. Third, J. Cowley, Barlow, near Chesterfield.

HAMBERGUS (Gold-pencilled).—First, T. Smith, Northwram, Halifax. Second, W. Froggatt, Walsley, Sheffield. Third, R. R. Tulip, Monkwearmouth. Commended, W. Harvey, Sheffield.

HAMBERGUS (Gold-spangled).—First, H. Carter, Holmfirth. Second, H. Bellin, Bradford. Third, T. Burch, Sheffield.

HAMBERGUS (Silver-pencilled).—First, W. Wood, Sheffield. Second, A. Nicholson, Sheffield. Third, H. Beldon, Bradford. Highly Commended, — Marshall, Nottingham.

HAMBERGUS (Silver-spangled).—First, H. Beldon, Bradford. Second, J. Dixon, Bradford. Third, H. Carter, Holmfirth. Highly Commended, R. Teebay, Fulwood, Preston. Commended, J. Camm, Farnsfield. A. Nuttall, Manchester. T. Griffiths, Eckington.

POLANDS.—First and Second, J. Dixon, Bradford. Third, Mrs. Robinson, The Priory, Mansfield.

ANY OTHER VARIETY.—First, R. Teebay, Preston. Second and Third, J. H. Craigie, Esq., Highly Commended, R. White, Sheffield.

BANTAMS (Gold or Silver-laced).—First, T. H. D. Bayley, Ickwell House, Biggleswade. Second, Miss G. Everett, Mowmouth. Highly Commended, E. Yeardley, Sheffield. — Harvey, Sheffield. Commended, E. Yeardley, Sheffield.

BANTAMS (Game).—First, J. Camm, Farnsfield. Second, G. C. Whitwell, Kendal. Third, W. Silvester, Sheffield. Highly Commended, J. Camm, R. Hawksley, Southwell. T. Procter, Settle. W. Silvester, Commended, W. Harvey, Sheffield.

BANTAMS (Any other variety).—First, J. W. George, Beerton Padge, Notts. Second, E. Hutton, Pudsey. Highly Commended, T. H. D. Bayley, Biggleswade.

DUCKS (Any variety).—First, Lord E. Hill, Norwood Park, Southwell. Second, Mrs. Seamons, Aylesbury. Highly Commended, J. W. George, Notts. Commended, S. Lowe, Tipton, Chesterfield.

SINGLE GAME COCK (Black or Brown R.).—First, G. W. Moss, The Beach, Aigburth, Liverpool. Second, T. Burgess, Salop. Third, D. Ashworth, Halifax. Highly Commended, H. Parker, Salop. Commended, T. H. D. Bayley, Biggleswade. J. Parton, Nantwich. W. Rodgers, Suffolk. G. Boot, Chesterfield. J. Proufield, Chesterfield.

SINGLE GAME COCK (Any other colour).—First, J. Kidger, Newbold, Chesterfield. J. Ewing, Tupton, Chesterfield. Third, J. Jackson, Firbeck, Chesterfield. Commended, S. Lowe, Newbold, Chesterfield.

SWEEPSTAKES FOR SINGLE COCKS.

SPANISH COCK.—Prize, Lord E. Hill, Southwell, Notts.

SINGLE DORKING COCK.—First, Rev. J. G. A. Baker, Southill, Beds.

SINGLE COCHIN-CHINA COCK.—First, T. Stretch, Bootle, Liverpool. Highly Commended, J. Stayley, Collingham, Newark. W. Wood, Sheffield.

SINGLE GOLD-PENCILLED HAMBERGUS COCK.—First, T. Procter, Settle.

SINGLE GAME BANTAM COCK.—First, T. H. D. Bayley, Biggleswade. Highly Commended, J. Camm, Farnsfield. R. Hawksley, Southwell. E. Barlow, Sheffield. C. Auckland, Chesterfield. Commended, R. Moon, jun., Liverpool.

SINGLE BANTAM COCK (Gold or Silver-laced).—First, T. H. D. Bayley, Biggleswade. Highly Commended, I. G. Park, Moresby, near Whitehaven.

SINGLE GAME COCK (Any colour).—First, T. Burgess, jun., Salop. Highly Commended, G. W. Moss, Liverpool. W. Rodgers, Suffolk.

PIGEONS.

Carriers.—First, J. Wood, Nottingham. Second, C. Felton, Birmingham. Highly Commended, J. Dakin, Sheffield. **Tumblers.**—First, W. Taylor, Sheffield. Second, J. Smith, Sheffield. Highly Commended, E. A. Hargrove, Birmingham. J. W. Edge, Birmingham. **Short-faced Tumblers.**—First, J. W. Edge, Birmingham. Second, E. A. Hargrove. Commended, E. A. Hargrove. **Jacobins.**—First, R. J. Wood, Nottingham. Second, E. Holland, Grasshill, Chesterfield. **Pouters.**—First, H. Childs, Birmingham. Second, W. Taylor, Sh field. **Fantails.**—First, J. W. Edge, Birmingham. Second, W. Taylor, Sheffield. Highly Commended, — Taylor. **Any other Variety.**—First, H. Childs, Birmingham. Second, R. J. Wood, Nottingham. Highly Commended, E. Holland, Grasshill. J. W. Edge, Birmingham. Commended, E. A. Hargrove, Birmingham.

RABBITS.

For length of Ear.—First, E. Brookes, Huddersfield. Second, G. Jones, Birmingham. Highly Commended, Mrs. Rathbone, Hasland. **Best coloured.**—First, W. Hodson, Chesterfield. Second, G. Jones, Birmingham. **For greatest weight.**—First, H. Rodgers, Brampton. Second, H. Simpson, Brampton.

CANARIES, BRITISH BIRDS, &c.

Clear Yellow Belgian.—Prize, H. Taylor, Chesterfield. **Clear Buff Belgian.**—Prize, H. Taylor, Chesterfield. **Variogated Belgian.**—Prize, W. Phillips, Old Basford, Notts. **Golden-Spangled Lizard.**—Prize, H. Taylor, Chesterfield. **Goldfinch Mule.**—Prize, W. Phillips, Old Basford, Notts. **Best Goldfinch.**—Prize, H. Taylor, Chesterfield. **Best Bullfinch.**—Prize, H. Taylor, Chesterfield.

LIGURIAN QUEENS:

DIRECTIONS FOR UNITING TO STOCKS OR SWARMS.

In compliance with the request of several correspondents, I have pleasure in repeating the instructions for placing Ligurian queens at the head of stocks or swarms, with such additional hints and modifications as have been suggested by a more extended experience.

As soon as the small box containing a Ligurian queen and her attendants has been received, steps should be taken for removing the common queen from the stock, or swarm, to which the strangers are to be united.

Where bar-hives are in use the operation is sufficiently easy, but should not be attempted without the protection afforded by a bee-dress and thick pair of woollen gloves. The services of an assistant similarly accoutred will be found very useful, but are not absolutely indispensable.

The middle of a fine day is the best time for the operation, which should be commenced by removing the stock a little either to the right or left of its usual position, which must be occupied by an empty hive, from which the crown-board and comb-bars have been removed. The crown-board of the full hive should then be slightly raised, and a little smoke having been puffed under it, must be shifted on one side sufficiently to expose a single bar, which may be carefully withdrawn after the attachments of the comb have been severed from the back and front of the hive by a bent knife. Both sides of the comb must be rigidly scrutinised, and any clusters of bees gently dispersed with a feather, until it becomes evident that the queen is not present, when it should be placed in the empty hive. The same process must be repeated with each successive comb until the queen is discovered and secured, when the bees may be either allowed to remain in the hive to which they have been transferred, or replaced in their original domicile. Sometimes the queen is not to be found on any of the combs, but may be detected among the stragglers remaining in the hive. In practised hands her discovery may be reckoned on with tolerable certainty during the first removal; but if she succeed in escaping detection, the process must be repeated until she is secured.

Driving is the best method to adopt with common hives or boxes; and the bees, having been expelled from their habitation, may be knocked out on a cloth and searched over until the queen is discovered.

Should the bee-keeper be unable to perform the operation of driving, fumigation may be resorted to, and the queen secured whilst the bees are in a state of insensibility.

It is unnecessary to describe the mode in which either driving or fumigation may be accomplished, as full directions for performing both these operations are to be found in nearly every bee-book.

Presuming the queen to have been removed, and the bees restored to their original hive and position in the apiary, measures must now be taken to introduce the Italian sovereign to her future subjects. The first step will be, carefully to remove the lid of the small box, replacing it with a slip of perforated zinc without permitting the bees to escape. The whole must then be inverted over an opening in the top of the hive containing the queenless stock, where it should remain undisturbed until the next day, when the perforated-zinc divider may be withdrawn, and the union will be complete. The workers that accompany the alien sovereign generally fall victims to the first fury of her future subjects; but if the bees are confined during the night by means of perforated zinc, and the hive conveyed into a warm room in the morning, and there kept until the bees are sufficiently oppressed to fill themselves with honey, a junction may then be effected without loss of life. Caution is, however, necessary not to continue the confinement too long. The small box itself need not be removed till the third day, when the bees will be found to have quitted it.

After the lapse of about thirty days,* young Ligurians may,

* Where bar-hives are used, this period of suspense can be abridged to three days, at the end of which time the result of the operation may be ascertained by an examination of the combs and the interior of the hive as above described.

probably, be discovered taking their first flight, and affording unmistakable evidence of the consummation of a dynastic revolution.—A DEVONSHIRE BEE-KEEPER.

BEE-HIVES AND THEIR APPURTENANCES.

(Concluded from page 129.)

ENTRANCES should always be cut in the hive, not in the board, as has been recommended by some writers. I have tried both, and decidedly prefer the former. It is very unhandy to place your hive temporarily on a small table, or any bit of board, and find you have no outlet for the bees. All boards must have a good level; any fear of damp penetrating the entrance is more imaginary than real. The blocks for contracting the entrance in board are clumsy and apt to go astray. I much prefer the simple mode (*fig. 9*) of sprigging on above the entrance a slip of wood,

Fig. 9.

with a check or rabbit on the inner low edge—a small slide the upper edge run off, sloping to the front, answers nicely; a bit of wood with a corresponding check on outer upper edge, an inch longer than the entrance, divided in the middle, makes a handy door, contractable at pleasure to admit but a single bee at a time, and a good defence to a weak hive against wasps. I prefer a good long doorway, 5 inches by three-eighths of an inch, should be kept fully open during the working season; its length is a great advantage, as every bee-keeper must have noticed the unaccountable blind-like groping of a bee on missing the door, often obliged to rise upon the wing, get into the track and effect a second landing before it be found.

COVERS.—All hives not enjoying the shelter of a bee-house must be protected securely from the weather; even these are much better of being wrapped up with some woollen stuff, for the maturing of late, and the promoting of early brood, till the return of summer heat renders it superfluous. Having expressed lately, in No. 646, the advantages of fresh straw hackles and Taylor's straw cylinder, and the benefits of protection generally, I would only now, in addition, draw attention to an octagon cover for Stewarton-hives—*fig. 4*, which has on my recommendation been adopted by several friends, who report favourably of it. It has certainly a very nice appearance when set up; it is 3 feet high to the eaves, and 18 inches wide inside, formed of inch-wood the top shaped out of the solid. The three back divisions work on hinges in one piece as a door, and are secured with a lock and key. In the central panel in front is a large pane of thick glass (seen in sketch) the corresponding panel behind, has perforated zinc of similar dimensions for ventilation, as well as in the floor-board, all closing with light shutters. In great

Fig. 4.

heat the door may stand ajar; should a loose bottom be laid above the permanent one, and a strong iron hook fixed above, the hive may be weighed within the cover. The cost is about £1.

COMB SUPPORTS.—I place within all my hives, except those intended for experimental purposes, such as the moveable comb-frames, a support of half-inch wood, fitted from the outside with screws or iron pins and placed about the centre; or in my collateral-hives by upright half-inch end-supports fitted to the ends of the cross ones, and fixed in a notch cut in the outer side of each end-bar, forming as it were a frame, the benefits of which have been already detailed in No. 628, under the signature of "A YOUNG BEE-KEEPER." Any aparian adopting this course will find the advantage of it; and were it more generally adopted, notwithstanding what writers may say to the contrary, you would be less troubled with querists in the truly pitiable fix of having the contents of their hives in a mess on the floor-board.

BEE-HOUSES.—Where a large stock is kept, and particularly should the locality be subjected to depredators, a bee-house is desirable. I once knew a bee-keeper give in on finding his last resort fail. He had for pedestals strong iron pillars, run with lead into heavy stones sunk deep in the ground, his boards bolted securely thereon. A series of chains from the pillars encircled his straw hives, fastening at their meeting at top with a stout padlock. He was robbed as usual, notwithstanding all his precautions; the bees appeared to have been first smoked, and the hives then cut out in portions like the sections of an orange.

A good cool substantial house is useful, a light-wooded flimsy affair decidedly bad for either house or cover; should the bee-keeper not be able to afford the former, he is much better with single pedestals than the latter. All houses must be closed up in front; those open to the sun and closed behind, are not unlike in appearance and supposable effects to placing hives in a bachelor's oven. Wooden houses must be boarded with inch stuff; if to occupy a central position in the garden, they look best if of an octagonal form. A fluted column at each corner both improves their appearance and is useful for preventing the wood "giving" at the corners by fitting the ends into grooves cut in the pillars. Coolness may be promoted by a half-inch lining inside, leaving a half inch or three-quarters of an inch space between the boards, filled up with sawdust, or some other non-conductor. The door, of course, to be in the least noticeable side. The back may be saved by building in front of the garden wall, or part of an outhouse—in that case it had better be of the three-sided form seen in *fig. 1*—the different

Fig. 1.

exposures keep down a good deal of quarrelling among the bees, than if they entered in a line; it has, besides, less of a stiff wall-like appearance. An upright roof has a detached look on such a building, and is, therefore, better screened behind a castellated parapet (as in the sketch) and sloped a little behind. If placed to a wall the form is better as seen in *fig. 2*. The door at A, if built

Fig. 2.

with a back, and a passage behind the door, could be placed at B, and the corners omitted, should that be considered preferable. If the ladies of the establishment are haunted with a constant dread of the disfiguring effects of stings, then the house may be placed at the bottom of the break, nearest the wall, the walk in that case passing behind it, where a ready access could be had into it through the door at the back, and the hives inspected without risk. There must be narrow windows at every entrance, sloped inwards at each side, so as to keep the hives as near the external air as possible, on which their prosperity greatly depends. This

window must be of thin stuff, with a shutter, and hinged to work outwards, lighted from above the window, of the form and raised in the manner of a frame-sash. When a hive is to be disturbed it can be raised a little; any bees making their escape fly to the light from the operator, and so gain their liberty. The shelves should be so contrived that each portion below a hive be moveable, for many reasons—such, for instance, as when the sliding door (*fig. 9*) be run in the part, can be raised with the hive, and weighed from the strong iron rod running along the length of the house above the hives; this, and the various details, too numerous to mention, will occur to every bee-keeper for his own convenience. The best house of this shape I have seen was built of brick, plastered inside, with a good flagged or brick floor, delightfully cool, and so clean that there was not shelter for a moth, nor a spider's web to be seen.

EXPOSURE.—The remarks in the "Bee-keeper's Manual" are very sensible on this subject. Apianians favourable to a north aspect, of which I have had a little experience, should satisfy themselves first that the spot selected be thoroughly dry and airy. There a well-found hive enjoys a dormancy till roused by the vernal influences, more in keeping with what is experienced in Russian or Canadian climates, with a doubtless economising of store. I have remarked, and it is a singular coincidence, noteworthy, and certainly favourable to the advocates of such exposure, that although runaway swarms have occupied in our roof different exposures, still within the last few years since I have taken a greater interest in their habits, I have observed they have invariably selected the north; the same predilection has been noticed at the neighbouring seat of an M.P. Some of those old pavilion-roofs in our county exert a mesmeric influence, extending for miles, quite unaccountably, and have become a standing terror to many a cottage bee-keeper; the worthy Baronet's last-named not among the least.

Having already exceeded all due bounds, I have only to plead in extenuation the reluctance one has when mounted on a hobby to tighten the rein; and after a trot in company with one of the cottagers above alluded to, in confirmation of what I have set forth, will then "pull up." On a hot summer day some years ago, as calm and scorching as any expectant bee-keeper could wish, there stood a most enthusiastic member of the fraternity watching his bees; nor was he disappointed, for the longed-for swarm rushed forth

and quietly clustered at the trysting place—a branch bard by; a noble first swarm it was. When about to place his glittering fresh straw hive over his prize (instead of their immediately beginning to descend facilitated with a cloth or a few leaves, our only Scotch method of hiving) the pleased twinkle of his practised eye suddenly changed on observing the black mass heaving, and numbers rise upon the wing, showing unmistakable symptoms of being off; down went the hive. Our friend possessing no small share of the indomitable "not-to-be-done" spirit of the Scot, divested himself at once of his upper habiliments, preparing to give chase. Away went the bees, and away went the bee-master at their heels, little dreaming what lay before him. Suffice it to say, they took him over the country in regular steep-chase fashion. The poor cottager soon saw what he had to expect; but, his blood being up, he would not give in, and followed helter skelter as best he could, through fields, hedges, and ditches, fording several burns and a small river, straining his visual organs all the while to keep the game in sight, till at last he finally tracked them to earth in the aforesaid roof of the then Lord of the Manor. Who should he encounter but the laird himself. At first he could hardly comprehend what the stripped, gasping, perspiring man would be at, pointing to his roof and demanding the use of ladders for the recovery of his property. At length perceiving the state of matters, he settled instantaneously on the spot (what would have been to him a second nature to discuss) the knotty point as to the rights of parties, by paying him handsomely for his bees and complimenting his pluck. They were thus left in undisturbed possession of the spot they had so much coveted.

The distance by the road is fully four miles; but as in the higher parts of our county these are but sorry specimens of engineering genius, being much more noteworthy for the picturesque than the straight, the bees' flight would be considerably less.

On laying down my pen for the present, I would remark, that were your many apianian readers more generally at the trouble of availing themselves of your Journal to communicate their ideas, the bee corner would seldom be vacant, information be diffused, beginners taught, and even our great apianian lights might stoop to gather something from such feeble scintillations, although couched in as limping sentences as those of—**A RENFREWSHIRE BEE-KEEPER.**

THE RABBIT (*LEPUS CUNICULUS*): ITS HISTORY, VARIETIES, AND MANAGEMENT.

(Continued from page 108.)

THE DUTCH RABBIT.

This pretty and useful variety is known in France under the name of *Nicard*. M. Didieux states they are much liked in Old Provence, on account of their prolific and hardy nature, and are very largely bred there.

They are very useful as nurses to bring up the young ones of fancy Rabbits, being such good milkers. It is astonishing to see one of these little creatures bring up five and six young ones in better condition than would be effected by another doe four times her size.

No breeder of fancy Rabbits should be without does of this breed. They are of all varieties of colour, both self and parti-coloured; many of them have a white collar round the neck, as shown in the drawing. The chief point of excellence in these little animals is diminutive size; and I have seen some extraordinarily small specimens, not weighing more than 1½ lb. This small size is obtained by breeding in and in. I cannot see the utility of reducing the size, but such is the freak of fancy.—**R. S. S.**

(To be continued.)

EARLY SWARM OF BEES—RIGHT OF FOLLOWING THEM.

DURING the latter part of last week my bees began to destroy drones, and on Thursday last, the 16th inst, sent out a very strong swarm, which pitched on a currant bush about 50 feet from the hive. This was at 10 A.M., and about one hour after they were safely lodged in a new hive, and well shaded from the sun, but at 1 P.M. they started off, and after some searching I found they had pitched on a wall at the top of a house where inlets had been made for air between the bricks, and where from inquiry I learn that bees have been for twelve years at least. The owner objects to have his premises disturbed, and I am very desirous of knowing if I have any right to claim the swarm, which at this early period of the season and the late destructive winter has made of additional value.—OBITER DICTUM, *Bridport*.

[Blackstone, in his "Commentaries," says, "A swarm which fly from and out of my hive are mine so long as I can keep them in sight, and have power to pursue them; and in these circumstances no one else is entitled to take them." Indeed, if the rightful owner quickly pursues the swarm, and keeps them in sight, and any one else should hive and keep them, it would be a larceny. We believe that if the bees have been quickly followed from the hive whence they swarmed, and have never been lost sight of, their owner is entitled to follow them on to another man's land and hive them. If the man on to whose land the bees strayed took possession of the swarm, or prevented the owner from doing so, we think the owner would have a legal remedy against that man. Of this we are quite sure—no one who is honest will prevent the owner of a strayed swarm following and recovering it.]

THE DOTTRELL.

I SEE by your paper of 14th inst., that you request any information respecting the Dottrell. I know but little of them in a wild state; but a remarkable circumstance occurred within a few miles of Birmingham, that, as relating to this truly singular and beautiful bird, will no doubt afford some considerable interest to a portion of your subscribers. It appears some parties were out at night "drawing for Skylarks," and unexpectedly secured a Dottrell. On being handled, it repeatedly uttered a loud wailing cry, that was immediately responded to by another bird of the same description some twenty yards in advance of the persons netting. Running on rapidly with the net, they secured this likewise, and they proved to be male and female, neither of them being injured at all by the capture. The next morning they were purchased by a general dealer in live birds, named Bates, in the Birmingham Market Hall, who called upon me to know "what they were." He also wished to know "whether I thought it possible to keep them alive and in health." I confess I then had my doubts on the subject. The plan he adopted was, at the onset to feed them entirely on earth-worms, and after some three or four days this diet was exchanged for shreds of raw beef, from which again he gradually "meated them off" on boiled egg, bruised hempseed, and bread, the same as the ordinary cage-food of Nightingales. They prospered well, became even improved in condition, and perfectly tamed, all in the short space of seven or eight weeks. The plumage of no wild bird could be better, being glossy and as close-lying as possible. The appearance of the eye was peculiarly mild and intelligent, and they quartered their cage with that methodical and graceful step so characteristic in all the family of waders. When they saw food preparing they came close to the cage side, and indulged in a low plaintive whistle. They would eat freely from the hand; even from the first they never attempted to fly against the wires or escape observation, but were very observant of all that passed, and occupied much time in preening their feathers. After being kept so long in this very confined space, they were, about two weeks since, sold to a party in London. Their remarkable familiarity, taking so freely to food so unnatural, together with their being captured so early in the season as the first week in March, has caused me to jot down these few particulars, as fancying some other individual might enjoy keeping so unusual a pair of pets, if chance threw them in his way.—EDWARD HEWITT, *Sparkbrook, near Birmingham*.

those birds. I have noticed this year—Swallow, April 5th; Chiff Chaff, April 17th; Cuckoo and White Throat, April 22nd; Nightingale, April 23rd; Swift, May 13th; Turtle Dove, May 14th.—B. P. BRENT, *Dallington, Sussex*.

DO CROSS-BRED RABBITS TEND TO A GREY COLOUR?

WILL "R. S. S.," who has had such great experience with Rabbits, or any other person, have the kindness to state whether, when Rabbits of any kind, which generally breed true to colour, are crossed with some other coloured kind, the offspring show any tendency to revert to the grey colour of the common English Rabbit? There seems to me sufficient evidence that when two differently-coloured and true breeds are crossed that there is often a tendency to revert to the colour of the wild aboriginal parent. I have seen striking instances of the rule with crossed Pigeons and poultry.—CHARLES DARWIN, *Down, Bromley, Kent*.

[We shall be obliged by replies to this query from any one experienced in Rabbit-breeding.—EDS.]

VARIETIES.

CREASOTE, or KREASOTE, is an artificial organic substance, generally obtained from the products of the destructive distillation of wood. It is procured incidentally as one of the constituents of wood-tar, from which it is separated by a tedious process. The principal supplies are obtained from Stockholm, Archange, and America. In the pure condition, creasote is a colourless oily liquid, with high refractive powers; but the commercial specimens are generally coloured yellow or light brown. It boils at 398° Fahr.; does not really inflame; but when set fire to, burns with a smoky flame. It has a hot burning taste, and is very poisonous to plants and animals. It has a great power of coagulating albumen, and hence may be employed with advantage in toothache; a drop placed on the exposed nerve coagulates the albuminous tissue, and destroys its vitality and sense of pain. The most important property possessed by creasote, however, is its antiseptic or preserving power over vegetable and animal organs and structures. Thus, ordinary meat treated with only one-hundredth of its weight of creasote, and exposed to the air, does not putrify, but becomes hard and dry, and assumes the taste and odour of smoked meat. Again, timber treated with creasote does not suffer from dry rot or other disease; and thus creasote, in a crude form, is employed in the preservation of wood. The crude pyroligneous acid of commerce, which is often employed in the curing of hams, &c., owes part, at least, of its preserving powers to the presence of a trace of creasote, which leaves its characteristic odour so well known as obtained from the burning of wood for the smoking of hams, &c. When used medicinally, creasote acts externally by destroying the cuticle; internally, in small doses of a drop or two, it is serviceable in arresting obstinate vomiting; whilst in large doses it produces nausea and severe vomiting; and, in many cases, fatal results.—(*Chambers' Encyclopaedia*.)

OUR LETTER BOX.

WORK ON PIGEONS (*J. Wilmore*).—"The Pigeon Book," by Mr. Brent. You may have it free by post from our office if you enclose twenty penny postage stamps with your direction.

TURKEY DYING RAPIDLY (*G. Ray*).—"The skin which encircles the heart being coated with a white substance like chalk," tells the cause of death. That encircling skin is called the pericardium, and the bird died of inflammation of that skin. Nothing would have saved the bird. Such disease is often occasioned by exposure to damp and cold. Nothing is more likely to produce it in Turkeys than their roosting at night in a cold, damp house.

CANARY CONTINUALLY MOULTING.—A Subscriber and Constant Reader asks why a yellow cock Canary is always moulting. Such a proceeding I regard as an effort of nature to get rid of an over-abundance of nutriment from the bird being too well fed. Discontinue the saffron, linsed and eggs, as well as tape or hempseed and all such stimulating food. Feed on good canary seed and plenty of chickweed and groundsel, with an occasional small piece of bread, apple, boiled carrot, brocoli, or potato, and allow the bird frequent use of the bath. Sometimes hanging in a room where gas is burnt will cause the birds to be continually dropping their feathers. Avoid draughts and excessive heat or cold, but the air cannot be too fresh.—B. P. B.

INCUBATION OF CANARY (*The Public's Man*).—"The period of incubation in Canaries is thirteen days, and I am not aware of any instance of deviation. The eggs that have been sat on for eighteen days must be bad, either from the defective incubation of the hen or from want of vigour in the cock. When the eggs have been sat on for a few days, it may readily be seen if they are good by holding them in the sun's rays, when they appear thick. If they look clear they are bad.—B. P. B.

ARRIVAL OF MIGRATORY BIRDS.—In reply to "H. R.'s" inquiry, I send you an account of the time I first saw or heard

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 70° and 47° respectively. The greatest heat, 90°, occurred on the 7th in 1846; and the lowest cold, 33°, on the 5th in 1856. During the period 137 days were fine, and on 101 rain fell.

GLASS FOR HORTICULTURAL STRUCTURES.

HORTICULTURISTS maintain a great difference of opinion on the article "glass" best adapted to garden purposes. A few years ago party opinion vented itself very strongly in favour of, or in condemnation of, the kinds then in use, or were introduced at that time; and although the glass controversy has subsided, there is a considerable difference of opinion still, respecting the best kinds of glass for general

horticultural purposes.

The impulse given to hothouse building by the legislature in abolishing the duty on glass, led to many errors in its first operations—glass of an inferior description finding its way into the market, was eagerly bought up, and its defects discovered; an angry dispute arose about its qualification, and a hasty condemnation of the variety of glass used was the result. The matter seems simple enough now.

Immediately on the repeal of the glass duty and excise, the sudden demand for good plain glass for window and horticultural purposes was greater than the home manufacturers could supply, and to add to this difficulty some strikes amongst their own workmen limited the quantity made and kept up the price. The result of this was an extensive importation of Belgian glass of very inferior quality, which was offered at such low prices as to tempt many to erect glass houses who otherwise would not have done so; but the evil of this low-priced article manifesting itself in the burning, scorching, and disfiguring of plants, a great outcry was raised against sheet glass; and an enterprising manufacturer at Sunderland introduced a description of rough plate glass, which certainly was a great improvement on the wavy, lens-like, Belgian glass. But whether this rough plate was better than good British sheet glass is a question on which some difference of opinion still exists.

It is certain the majority of glass structures are glazed with sheet glass; so that, unless there be some benefit attached to rough plate unknown to the general public, there is every reason to infer that the other kind is most adapted to the general wants of the mass of exotic horticulturists.

The qualities needed in glass used for horticultural purposes may be simply described as allowing of the sun's rays passing through it, as little altered as possible in their character, more especially in their direction. I believe I am right in saying that the very best kind of glass made alters the sun's heating powers in one way or other and the most common kinds, presenting a wavy surface, necessarily act as so many imperfect lenses, diverting the sun's rays all to one point or line, to the

injury or destruction of the plant against which they are directed. Very common sheet glass has this defect, as well as being more or less interspersed with specks or scratches formed in the making. All these ought to be guarded against, and plenty of sheet glass is free from it so far as to be suitable for cultural purposes.

It was with a view to neutralise all effects from the collection of the sun's rays under glass, that the rough plate variety was introduced. This presenting a finely corded surface to that luminary, diverts its rays from a direct line, which it would have in an ordinary way when under good glass, to a diagonal direction right and left of every cord or ridge on its surface, which is something like one hundred to the inch. I believe it does this, and the glass being strong, it can be used in large squares available to the fashionable glazing of the day.

To these good qualities of rough plate has been added by some that no shading is required beneath it for plants that are in bloom, or for cuttings striking; but this assertion cannot be borne out, for many who have been induced to have it on this belief insist that it is really hotter beneath it than under clear sheet glass. Be this as it may, it is only fair to say that rough plate glass possesses no merit which may not be had in sheet glass, and is deficient in some of the points of great importance in plant-house building. Foremost amongst these being appearance, which is certainly on the side of sheet glass; the other looking so rough, obscure, and dirty, while good sheet glass has a nearer approach to polished plate.

As all sheet glass is not alike, it is better to say a few words to guide the inexperienced in the selection of the kind best suited to his wants, the qualification "cheapness," being also included, though not, perhaps, in the same sense it is often present to him, for many low-priced articles are very dear, and glass structures are sometimes of that kind.

Assuming the purpose for which glass is to be used to be a house or structure, either for plant-growing or fruit-forcing, or any modification of either, or both combined, I would certainly give the preference to sheet glass; but I would not by any means advise purchasing a cheap common kind. On the contrary, I advise nothing thinner than what is called 26 ozs. to the foot. Sheet glass to be used for fixed lights; and if the squares be very large I would have it still stronger. It is a great mistake to glaze with thin, poor glass, for the expense of glazing, painting, and woodwork, is all the same, whether the glass be thick or not, and in an *£. s. d.* point of view, glass generally costs less than either of these items, and for a period of ten years thick glass will be the cheapest. I, therefore, have no hesitation in advising the use of good thick sheet glass in all cases where a permanent structure is concerned. In doing this I by no means undervalue rough plate, but as I regard sheet glass of the same price so much better, I cannot but give the preference to that kind.

We have several kinds of sheet glass in use here from 16 ozs. up to 26 ozs. The last, however, being the best, and much less breakage with it; and as that is an impor-

tant item in expense, as well as an annoyance, its avoidance ought not to be lost sight of in ordinary glass for such purposes.

It is needless entering into any other feature of sheet glass than its thickness, as the price generally determines all the rest. Suffice to say, that the amateur ought not to grumble at giving 6*d.* per foot for his glass; and by doing this he will save much during the next ten years, keeping other points in view at the same time which will be explained hereafter.

It is hardly necessary to allude to any other description of glass than those above, as the old-fashioned crown glass is fast falling into disuse, and few, if any, new structures are glazed with it; old ones, however, being repaired as before, and the still older-fashioned under-duty glass is still faster disappearing, with no chance, or, I dare say, no wish for its resuscitation. There is another kind of glass which I think might be advantageously introduced—that is, slightly coloured glass. I never had much experience with this but once. I had a small plant-house glazed with sheet glass tinted green rather strongly, and plants did remarkably well in it and kept a long time in flower. No shading being wanted I did not experience any inconvenience from it in the winter season, and the appearance of things inside of it had a pleasing effect. Hereafter we may possibly have show-houses for plants coloured in this way, rather than resort to the unsightly appendage of shading; and I for one would be glad to see some of them so, not glazed with gay colours, but some sober tint calculated to soften the sun's rays falling on flowering plants, and hastening them on to accomplish the purposes they are by Nature destined to fulfil—that is, to flourish, flower, and perfect their seed. In ornamental plant culture the object is to delay the blooming period; and if this can be accomplished by a neat-looking glass roof without the aid of shading, so much the better. But I have said enough on the subject of glass, and will at a future time give a few remarks on hothouse-building in general.—J. ROBSON.

ARRANGING FLOWERS IN BOUQUETS AND VASES.

(Continued from page 153.)

CHAPTER ON SHAPES.

I BELIEVE I did intend that this chapter should be about flowers themselves, and how to mount and wire them, and put them all together, but I begin to think it would be wrong to adhere to that plan.

All that is very nice to know, and very useful, but yet not so utterly essential as the making of forms and shapes; and as I should be very sorry if the little designs should not prove useful, I think it is better to begin at the right end though it is the dullest of all dull subjects, and to write at once of how to manage shapes.

When shapes are provided, patterns are worked out easily, and I fear it is nearly impossible to form them, at least in variety, till these shapes are seen to.

They can be made in a variety of ways. Some have frames of very fine green wire, like the old-fashioned little violet-baskets, only smaller meshed, so that a single stick, or a stem stripped of all its leaves, passes through each hole, all being bound together underneath the frame.

This is one of the easiest plans of all, the holes being, of course, arranged in circles, and the flowers being carefully kept to a very even surface; the effect is then extremely good, and particularly lasting—at least, for wearing. As commonly arranged it has only this disadvantage, that when the petals begin to fall, or the flowers to shrivel up, it is no longer ornamental, while more solid masses look less objectionable.

For one or two days' use, however—as for a dinner-

table, or for carrying in the hand, nothing can do better. It is exceedingly light to hold, and looks light also while it is at the same time very firm, and for economy of flowers it is unsurpassed.

I proceed to give the receipt as precisely as in a crochet-book for making this, overcoming, I hope, its usual reproach of bareness. Having fixed the required size of the bouquet, when complete take a slight wire or pierced frame two inches less in diameter than you propose for the extreme edge of the solid bouquet—that is to say, the extreme edge of the last connected row of flowers. There may, of course, be a stray Fern leaf, or even a fringe of Fern leaves, to come beyond the frame; but I do not count these, because they are not solid, and must not therefore, be included in calculating the size.

It is not at all a disadvantage when, as is often the case, the frame, though otherwise nearly flat, rises apparently a little too abruptly in the middle. A large flower is best for that place, and these are always better when they can rest upon the solid foundation. I only mention this now, however, as regarding the frame; we will talk of the flowers later.

The frame is made much more convenient by having a stem, or rather two or four separate wires with a space the size of a penholder between them, just like a parasol handle; and though it must be a very ingenious young lady to make the wire frame, the stems can be affixed without any uncommon stretch of skill. Where young ladies do try making their own frames, my very earnest advice to them is to use silver wire. The quantity wanted is not great, and the ruin of gloves that is caused by other kinds would be likely to be vexatious. Silver is also much more easily bent.

The circumference of the whole is, of course, three times the diameter. So, if the frame is to be six inches, a piece of wire nineteen inches long should be cut; and then, unless the flowers are meant to be used very small indeed, I think I may say the succeeding lengths should be each an inch and a half shorter, till the last makes a circle about the size of a sixpence. This allows for four rows between the centre and the outside edge—six in all. But as it is better to allow an inch at least for a beginner for fastening the ends, the wire should be cut into lengths of nineteen, sixteen, thirteen, ten, seven, and four inches. Each of these pieces should be twisted or neatly hooked together into circles of their respective sizes; and then, the centre one being formed, three wires should be attached to it in the manner of parasol frames—going out towards the edge, and dividing it into three parts as equally as may be. These wires have to be each six inches long; another inch must, therefore, be allowed for twisting.

Laying the concentric rings upon the table in their proper order, the three frame wires are passed in and out till they are firmly hooked upon the outer circle, the others being secured in their places by a knot of netting-silk. It is very easy afterwards by gentle bending to give the desired curve to the upper surface; and two or three long, strong wires, at least eight inches long, being attached to the centre circle, the parasol frame will be found to look quite complete, and it can at any time be enlarged by another ring supported by two extra pieces of the wire frame; or the three already named may be cut each an inch and a half longer than was required, so as to turn up or down as wanted.

It would be better if the wire were cut in the lengths required at the shop where it is bought, as in that case it would be in perfectly straight pieces.

Some fancy repositories sell this sort of wire. It is expensive at a jeweller's, and I have been told by French friends that the French shops where rosaries are made are the best and cheapest for it.

Where the frames are not intended for carrying in the hand, but only for vases or for dishes, the zinc wire can be used, which is very easily bent into shape. Of course, square dishes or ovals can be filled by wire on the same

principle; and in squares it is, perhaps, better to arrange them in a centre-circular bouquet with the corners filled up, because, unless the wire frame is in the form of rings, it is so difficult to prevent the effect from being liney.

The saving of flowers effected by this plan is something marvellous.

In cases where very small flowers are used, a round piece of green or black silk netting laid on outside the frame and fastened over all round the edge answers every purpose; and where wire is really unattainable or not to be managed easily, the frame can be made entirely of such netting on a cane or whalebone frame, this being so far advantageous that it is exceedingly light and also inexpensive.

These directions are very dry and uninteresting I fear; still we must put up the scaffolding before we can accomplish building, and our work hereafter will be made very easy by arranging these things rightly before we attempt to proceed further.

ROSE BOUQUET.

There ought to be now no difficulty in giving the first June bouquet.

I have set my heart, in fact, on Roses; the beautiful white Banksia, and the pink little Rose de Meaux, and then a fringe of Lilies of the Valley and pale Blue Bells, will surely finish off our bouquet in an artistic manner.

A small, stiff, central bunch of green, which one sometimes calls a faggot, is first prepared as usual; three of the pretty pink Roses are carefully sought out and mounted in a spray, the heads being closely arranged together, and then should come a few of the pure white Lilies, with just two or three of their smallest leaves peeping up as well, encircling the Roses; and a wide even circle two or three Roses deep. How prettily it sounds, that measuring by Rose-buds! The edge of the band, keeping very even, succeeds the Lilies.

So far for the first circle. The second, after a frill or edging again of the pretty Lilies, should be a mass of Rose de Meaux. Sweet little Roses indeed they are (and, oh, so charming for a dwarf Rose-hedge). They should be closely set together, level at the top, and even in their adjustment, and wider a little than the row before.

Thirdly comes the border of double width, in which I hardly can tell how to arrange the flowers—all ways are so pretty when the flowers are such as these I speak of. I think I should mix them entirely, white and pink Roses, Lilies, and Blue Bells all being joined in a mingled band. And yet it would look so pretty with first white and then pink,—each row divided with those perfectly lovely Lilies, and the sky-blue Blue Bells also in a wide final edging, and Fern and Lily leaves to finish off the whole.

Roses and Lilies ought to satisfy very fastidious tastes, and the beautiful little early Scotch Roses may often lend their white flowers to take the place of Banksias.—E.

(To be continued.)

SPRING FLOWERS, ANNUALS, AND HERBACEOUS BEDDING PLANTS.

WHO recollects the kind of bird which poor Barnaby Rudge used to pet and prize so much in one of Mr. Dickens' tales? You recollect Barnaby Rudge was a daft body, and the Floral Committee were put in remembrance of his whimsicalities this spring by the exhibition of his namesake plant from the Wellington Road Nursery—*Rudaea macrocephala*, or Rudge with the large head. This plant had a wedding nosegay for a head when we last saw it before us, on a thick flower-stalk, stout as that of a "Good Gracious" polyanthus, with a polyanthus head of orange-like flowers of ivory substance at the ends of all the branches of a Magnolia-glance-looking plant, and of the size of a small gooseberry bush. This seemed to the Floral Committee will be the ultimatum of that kind of Rudge when it comes of age

in the hands of the specimen maker on the one-shift system; therefore, every family, from the Royal Family, who has a store to grow a *Rudaea macrocephala* and a family of daughters to wed out into the world, ought to grow this *Rudaea*—the only plant, perhaps, which produces, in one head of bloom, a perfect wedding nosegay.

Next I will notice a Pansy, the best Pansy in this world for contrast and for making converts to the family. I also will foretell that seven gardeners out of every ten of them all over the country would run after this Pansy, when I say it is the very style and pattern of the two colours in *Torenia asiatica*. Split up a *Torenia* flower in fancy Pansy shape, and you have the *Maggie* Pansy. Stretch your ideas now to the extent of one hundred yards running north and south—let that be the first border line to your ribbon; let it be 10 inches or 12 inches wide, and as thick as it can grow. Let it be in full bloom, and look on it from the south end about 11 A.M. or 1 P.M., and imagine 10,000 magpie flowers looking you full in the face, and full of flourishing impulse from the full depth of a fully pulverised border of good, light, rich compost, mulched over in March or April with cocoa-nut-fibre sawdust in which Pansies take more than delight to breed and multiply of their own accord, as I can tell from the experience with the yellow Pansy I had from Mr. Sims, of Foot's Cray, seven years back. 1859 was just warm enough for it, and 1860 just wet enough and no more for it. All the frosts since 1853 were but enough to keep it from growing the year round, and when the gales knock it against itself and other things the fragments root as seedlings, and cover the borders with ready-made plants; and all this from the cocoa nut pulp, as the natives call it. This magpie flower is the best of them for ribbon lines because it blooms on and on for months and months, like that yellow one, and like the blue *Trentham* one, of which I heard a great deal, but never saw it, but should judge from what I heard of it that the magpie would be the first row, the yellow next, and the *Trentham* blue the third row of spring running ribbons; then a row of the whitest kind, to cut the three distinct contrasts in front from a full collection of kinds, mixed after your own fancy, behind the white row. But for all that is good in flowers do not make a mixture of kinds in connection with any system which attempts a contrast of colours in running lines without the bar of a white between them, and nothing short of white will do to cut the two systems from forming the groundwork of a fancy puzzle.

The newest idea of a flower-bed is this, and it is carried out to the letter: A fancy-shaped bed, which Euclid could not compass, is lined all round the edge with young plants of Baron Hugel (not Baron de Hugel), and the rest of the beds—which in no part is a yard from the Baron—is planted with Purple Orach. The Orach plants were from 6 inches to 9 inches long, and were laid nearly flat on their sides at planting out of pots. But that is not what brought up the purple Orach after the Pansy, but another fancy which struck me at the time, and which might escape my memory at the proper moment without thus booking it. I have been calculating 800 miles of variegated edgings in the flower gardens of England alone; but if it be three times more, I want next year between the middle and end of March to have as many miles of Purple Orach plants pricked out just beyond the variegated line or lines; and where the variegated is to be over 4 inches from the sides to have another row of Purple Orach pricked out at 3 inches or 4 inches apart, just like pricking out young cabbage plants from the seed-bed. The sowing to be done just three weeks later than for early spring cabbage plants, which is the simplest way to put it for gardeners. In that case you have two rows of this rich purple standing 6 inches or 8 inches apart, and the space between these rows may be full of Crocuses at the time of pricking out the purple; then, if Mint or Cerasium is to be the edging, let each be from very young cuttings, and be put in in two rows, and let the purples be 6 inches apart; but if the variegated edging is to be of Mangles' Geranium, or any other variegated sort, let the purple lines stand 8 inches apart; and all through April, May, and to the end of June, the Purple Orach is to be in contrast with the white edging, and at the same time give the same effect as so many lines of annuals used to give at Shrubland Park, where every other row all over that large garden was a row of some annual in the planting of 1851, when every bed in the garden was full of gay bloom in the last week in June; which could not have been done there at that period without the annuals. I never see a poor miserable lot of bedding-out plants put out to nurse in the

flower-beds by the end of May without wishing I had never encouraged the bedding system, or said more pointedly the benefit that might be derived from the true use of annuals—that is, to use them by the ten thousand in aid of bedding-out plants. I can see no reason under the sun why a flower garden of any extent should have the lapse of one week without flowers from the first coming of the Crocus through the necessary change to pot plants and planting out towards the end of May, but the one substantial reason of expense of seeds, and of looking after the seedlings in bad weather. Instead of despising the annuals I would insist on gardeners learning how to manage annuals properly, and unless they could get full sixty kinds of them in bloom for me by the time the bedders were being put out, to bloom whilst the bedders were getting their teeth, as it were, I would show them how to do them.

Then, if I found the cost to be more than would suit me, I would fall back on a set of our best herbaceous plants, and take a score of kinds of them, or a couple of dozens, and I would begin the spring with *Ranunculus amplexicaulis*, the earliest white bedder help on the list. I said lately that this was grown largely at the Pine Apple Place Nursery, by Mr. Arthur Henderson, on purpose for such work; then the *Arabis alpina*, *alias* *præcox*, and *alias* *alba*, comes in at as early a period and lasts as long, about six weeks. *Alyssum saxatile*, plain, and variegated, and evergreen, follow on in April, and should be had in quantity. *Iberis Tenoreana*, a sweet, early, May-flowering plant. *Iberis corifolia* the same. The *Delphiniums*, as *formosum*, *Hendersoni*, *magnificum* and *pulehellum*, or any others near them, are handsome and most useful helps. The new *Dianthus*es, and Capt. Trevor Clarke's mule Pinks, single and double, are most useful, showy, and easily transplanted at any period of their growth. *Oenothera prostrata* and *serotina*, as well as *taraxifolia* and *macrocarpa*, are all very lasting, but the last two will not bear to be removed often or during the summer. *Lychnis Haageana*, *Sieboldi*, *Bungeana*, *coronata* and *fulgens*, require only to be kept young, or as biennials, to be most useful and very telling. The old, pretty little *Saponaria ocyroides*, to be kept young, like a mountain pink, is one of the nearest front-edge plants we have. In rich or damp soil, the Forget-me-nots are all useful, such as *Myosotis azurea grandiflora*, *montana* and *palustris*, and *palustris alba*, can be moved from place to place the whole summer. *Platycodon grandiflora* is another, the most showy of all the Campanulas. The little white *Campanula pumila*, if it were divided every April, would bloom for nearly three months from July, and occupy no more than 3 inches or 4 inches along the edge of a bed or border. *Campanula carpatia*, blue and white, treated in the same way, last out the whole of the flowering season. In May no garden should want a bed of *Dodecatheon gigantea*, which would easily remove when the leaves begin to fade, and rest till the turn of the new year. *Phlox verna* is a true bedder for April and early May, and to be kept young for runners or cuttings. *Phlox procumbens* equally good for May; large round patches of it are now only going out of flower at Surbiton; *nivalis* and *subulata* are nearly as good, and the four are suited for the front of beds and borders, just as *Polyanthuses* and *Auriculas* were a month earlier.

To represent the new class of *Phloxes*, none of the old is so good as *Criterion*, which is striped carnation-fashion, and lasts in bloom a long time, rising from 2 feet to 3 feet high, according to the soil it is grown in. *Chelone barbata*, and several kinds of *Pentstemons* and *Potentillas*, make the very best border plants either in masses of one kind, or in single patches. There is no end to the new races of *Phloxes* and *Pæonias*, also the new *Pyrethrums*, as *carneum* and *roseum*, *Duchesse de Brabant* in the shade of *Carmine Nosegay*; *Prince Alfred*, a purple crimson, fine, and fulgidum, a blood red, besides others that I have not yet seen. *Antirrhinums*, again, remove perfectly easily from the seedling state till they are in full bloom, and back again the same season after they are over, so that no room is lost to the great work of the season—a perfect mass of bloom in all parts of the ground.

Then there is no end to hardy variegated plants, and in the spring most of them are as handsome in their variegation as others are for their flowering beauty. Besides, by the man of quiet mood and perennial comfort, none of these need be at all removed save once in two or three years; but such as I have indicated to be kept young need to be looked to about making cuttings of them, or dividing them every year, or once in two years at the farthest. But every gardener in the country could add some more names to this general selection of herbaceous

plants, which last a long time in bloom and are not difficult to manage; and no greater compliment could any one of them pay to the new rank and title of the good old and true COTTAGE GARDENER than to add half a dozen kinds of equal merits with those here indicated, and at the same time to say how they should be done by; for all my own experience goes to prove that bare lists of plants do but puzzle and perplex any mortal as to how to dress them, or keep them, or where to put them, and how to make the most of them. But I made the following up on several occasions I had been at Mr. Salter's, Versailles Nursery, and if I keep it much longer I shall not say what may happen.

I shall begin with the Greek *Valerian*, *Polemonium cornu-leum variegatum*—the very prettiest edging plant in this world, where the light, deep, rich soil enables it to be as it has been with me till I was foolish enough to lose it altogether through sheer greediness in excessive propagation; *Veronica chamaedrye*, which will be in the bedding lists soon, as it had a first-class certificate for a hardy edging plant for the million from the Floral Committee—this will beat the hardy *Alyssum variegatum* or its substitute; many other *Veronicas*, *Vincas*, and *Verbenas* with well-marked variegations; *Sedum acre*, *var.*, and *Sedum telephium* two sorts; *Saxifraga granulata*, a gem for rocks if not disturbed; three and five-lobed *Shamrock* for St. Patrick's patrimony as deep in rubrum as *Orach* is in rubicundum—dark purple bands, in fact; *Symphytum officinale*, a grand thing, with bands as in ribbon grass, but four times broader; *Agrostis vulgaris* and *colorata*, very nice; and *Arundo phragmites* with golden chains; *Calystegia sepium*, *var.*; *Comarum palustre* ditto; *Lily of the Valley* as ribbon grass; *Solomon's Seal*, or *Convallaria*, *Polygonatum*, and *C. Sieboldi* the same, very handsome; *Festuca glauca*, for verges to green drives in plantations, and to carriage-roads where they run through rough underwood in plantations and large shrubberies. Coming from the London lodge, such verges never want cutting or weeding. Many *Funkias*, *Centaureas*, *Irises*, *Gromid Ivies* or *Glechomas*, *Lamiums*, *Rudbeckias*, *Melica* and *Mentha*, *Veronicas* and *Vincas*, *Sedums* and *Salvias*, and indeed to the number of 250 kinds, and every one of them a variegated plant, quite a novel sight of itself. But the gentleman on Brixton Hill who gave me the yellow *Polyanthus*, and who has a regular museum of rare plants, showed me five or six plants of the Golden Variegated *Aucuba japonica*, which few people can do properly, but which he does as regularly as the Flower of the Day, even to the bark of the young wood—all of a glowing golden yellow in immense stripes, spots, and blotches.

D. BEATON.

THE AURICULA BLOOM OF 1861.

THE idea entertained by a grower of these flowers—that frost was good for them, would almost seem to be (however ridiculous it appeared at first sight) correct. Never have we had a more severe winter; never have our noses been so cold or our coal bills so heavy; and yet, from all I see and hear, never was there a finer bloom of these flowers than the present season has witnessed. But we must not, therefore, conclude the above axiom to be true. “The *post hoc* and *propter hoc* are two very different things.” Cold frosty weather implies an absence of damp, and this being the great foe to the Auricula, the season has favoured it; but had the weather been equally dry without frost and snow, the advantage would have been equally great. From one grower indeed, and he one of no mean celebrity—Mr. Lightbody, of Falkirk—I have received a very unfavourable report; but as he has himself, I grieve to say, been an invalid, it is very possible that may have had something to do with his bloom, though he attributes it in great measure to the fact that his trusses were all heart blooms. That, by-the-by, opens out a very curious question, of which I can see no solution on any physiological grounds. How comes it to pass, that if an Auricula throws up a side bloom it is pretty sure to be in character; but that if it be from the heart of the flower—no matter what the edge may be, green, grey, or white—it is just as likely to come in any other class as the one it belongs to? Again: I have had kinds which one year have come all green-edged, the next year all grey. Can Mr. Darwin, Mr. Beaton, or anybody enlighten me on the first of these points? The latter may be the effect of season, but the former occurs in all seasons.

There has not been for many years—not, I should think, since the gatherings at the Horns Tavern, Kennington, when

John Dickson was king of growers—so large a display of Auriculas seen in London as at the April Show at the Royal Botanic Gardens. I was, I regret, unable to attend, but it was a large step towards what I have long desired—a national Auricula show. Mr. Turner sent a large collection; and my friend Mr. Jeans, of Alford, a basket of new varieties, besides his lot for competition; and I understand that many were the admirers who crowded round them during the day. May we not hope that some of those admirers may be turned into growers, and thus the patrons of this beautiful spring flower be increased in number? In the hope that such may be the case, and for the information of those who are growers, I append some notes taken of both old and new flowers this season.

GREEN-EDGED CLASS.

Booth's Freedom.—This most difficult flower to grow, as most people find it, had with me only three pips, which were very fine; but my brother tells me that Dr. Plant, the famous grower at Monkstown, near Dublin, exhibited it with nine or ten, and each pip as large as a florin.

Dickson's Duke of Wellington.—An old flower; a great favourite about London, but no way thought of in Lancashire—too full of colour, and striking on a stage.

Dickson's Duke of Cambridge.—This has not done well with me this year. The ground colour is very bright—a violet purple, but the plant itself is not strong in constitution.

Dickson's Matilda.—Neither did this bloom well with me this season. These caprices are very odd. Last year it was excellent. It has several faults (we florists are very particular, I fear) amongst them that of not throwing up its footstalk sufficiently.

Leigh's Colonel Taylor.—An old, and, I think, over-rated flower. Petal pointed, paste too thin, and stem not strong enough.

Finlayson's John Bright.—In sturdiness and want of refinement well named. A new flower of immensely vigorous habit. Eye not colour enough, but as a stage flower cannot be dispensed with.

Lightbody's Sir John Moore.—At one time I thought this must go to the border; but, with less mauve, it has been a presentable flower, and I shall retain it.

Page's Champion.—One of the oldest and best of its class. A delicate-constituted plant, and very difficult to obtain. I had one early and good bloom of it.

Oliver's Lovely Anne.—An old, easily grown, and useful variety. Sometimes green and sometimes grey in its edge.

Campbell's Lord Palmerston.—A good variety. Somewhat pale in the eye, but very flat. A good dull green.

Smith's Lycurgus.—A lion! Edge green, with a good deep ground colour. The eye yellow. Foliage large and considerably serrated. Vigorous in habit, and sure, I think, to push aside some of its older companions. Florists will see a very admirable portrait of it in the September Number of the "Floral Magazine."

Howard's Lord Nelson.—A good old variety. Faulty in some points, but easily grown.

Clegg's Lady Blucher.—A pretty flower, though somewhat pointed in petal. Ground colour a light purple. Edge apt to get foxy.

Smith's Richard Cobden.—Fine and vigorous growth. Edge a good green. Large amount of ground colour. A noble stage flower; and, as it is so robust, it will find its place into most collections.

Smith's Lord John Russell.—Good lively flower. Clear in the edge, a little too rough, and somewhat thrum-eyed.

GREY-EDGED CLASS.

Chapman's Maria.—A high-priced and exquisite flower. Its colour is of the most intense violet; and there is an air of singular refinement about the flower, which, despite the indecision of its edge, places it in my mind at the top of the tree.

Chapman's Sophia.—Another very beautiful flower, but not equal to its sister.

Cheetham's Lancashire Hero.—Perhaps in form the most perfect of all Auriculas, though wanting in decision of edge. Colour deep, eye good, pip flat, and altogether a model flower.

Fletcher's Ne Plus Ultra.—In size certainly deserves its name. Pips as large as half-a-crown, are not uneven, but then it is coarse. It is, however, a flower that is sure to attract, and I do not find it all weakly in constitution.

Fletcher's Mary Ann.—A neat prudish-looking flower, quite the old maid of Auriculas; but like many of that too-much-despised class, most valuable. (I only wish the old bachelors

were half as unselfish.) A good exhibition flower, though it does not make a large plant.

Lightbody's Richard Headley.—A very late-flowering kind. Foliage peculiarly beautiful; pip not large, but good in shape. So late, as I should think very difficult to get in for an exhibition. My plants are in bloom now (May 28).

Maclean's Unique.—A fine, bold-looking flower. Its eye somewhat large; but I do not know a more striking grey edge than it is.

Waterhouse's Conqueror of Europe.—An old flower that I took prizes with twenty years ago, and still a winning sort. Constant, a good grower, and quick propagator.

Dickson's Lady Jane Grey.—Of this I had a very fine truss. The petal is round, the edge good, the eye orange, habit excellent, and lasts very long in bloom.

Headley's George Lightbody.—Alas! my plant is gone. Mr. Jeans says he had it very fine, although somewhat defective in ground colour.

Rev. George Jeans (Turner).—A very neat flower in the way of Sykes' Complete. Good eye, edge decided grey. Quite new, and not let out yet.

Mr. Feasch (Chapman).—Cannot equal Mr. Chapman's other two flowers; but is very pretty in colour. The pip is large, and the habit of the plant good.

WHITE-EDGED CLASS.

Taylor's Glory.—Still unapproachable as a white edge. The colour beautiful violet, paste thick, edge pure white; truss large; foliage very mealy. I have had some fine blooms this season; but have seen it with Dr. Plant with pips as large as a florin!

Lightbody's Countess of Dunmore.—A good flower. Mealy foliage; ground colour deep chestnut; orange tube. Fine trusser, and good grower.

Hepworth's True Briton.—A good white edge, but has the fault of rarely flattening. Colour dark plum; foliage smooth and green.

Popplewell's Conqueror.—A very old but very useful variety. Edge too much approaching grey, very mealy and serrated foliage; habit good, and an indispensable flower, whether for exhibition-table, or stage.

Smith's Ne Plus Ultra, wrongly named, for Taylor's Glory is a long way beyond it, still the flower is a good one.

Gaines' Model.—Too small even to be fit for an exhibition-table. The pip is circular and flat, and it will be found pretty for the stage.

Traile's White Rival.—Coarse in texture, too much colour. Perhaps another season may modify it.

SELF CLASSES.

To most non-connoisseurs this is the most attractive of the four, the various shades of colour, from the deepest maroon approaching to black, to the liveliest light blue, render it eminently attractive, and of late some valuable additions have been made to it.

Netherwood's Othello.—The earliest-blooming of all Auriculas with me. Colour a deep maroon; tall in growth, and apt when fully blown to throw back its petals; but a desirable flower.

Martin's Mrs. Sturrock.—I had some excellent blooms of this variety. A dullish-crimson flower, very flat, with good paste and eye. A sterling variety.

Lightbody's Meteor Flag.—A large and clear-coloured flower, but I think beaten out of the field by some of the newer ones.

Richmond's North Star.—A very beautiful light lively blue flower, well shaped, paste good, and eye pure yellow.

Faulkner's Hannibal.—A good deal has been said about this flower the last two years. I saw it this year along with Squire Muunday. It certainly is the same, is rough, coarse, vigorous in growth, and striking as a stage flower.

Spaldry's Blackbird.—One of the best selfs. Colour deep purplish-brown, somewhat reflexes when fully open, and throws up its anthers too much, making it thrum-eyed.

Volunteer (Turner).—Petals large, and a circular eye; too light, and paste too thin. The foliage is good, and, doubtless, it will be generally grown.

Spaldry's Metropolitan.—A very pretty flower in the style of North Star, but not equal to it.

Redman's Metropolitan.—A pretty flower, which soon, however, fades its colour, and then looks as if it had been floured. Very small foliage. In winter you would imagine the plant would do nothing, but it throws up a fine truss.

Chapman's Squire Smith.—I have grown this two seasons, and unless it improve I shall not grow it after next year. It is certainly better this year than it was last.

Such are some of my "observations" for this season; and I am more than ever convinced, that plain common sense and an absence of quackery will enable any one to grow this charming spring flower. We poor florists have been so thrust aside by whipper-snappers, like "Tom Thumbs," yellow *Calecolarias*, variegated *Mint*! and every thing that can be pressed into the bedding line, that we must stand up for ourselves, or we shall be overwhelmed. Let not lovers of flowers be afraid of trying their hand, and may success attend them.—D., Deal.

CULTURE OF THE GRAPE VINE.

VINES IN THE OPEN AIR ON WALLS.

(Continued from page 137.)

In my last paper on this subject I described what I consider is the best and simplest mode of pruning and training the Vine on walls. The alternate mode of training and pruning the Vine may be varied to suit circumstances. The same principle is that called horizontal training. A main stem is carried up to the top of the wall, and side shoots at regular intervals are trained at right angles from it (fig. 6).

Fig. 6.

This plan answers admirably for Vines trained against the walls of a dwelling-house, and also against a wall purposely set apart for Vines. In the latter case the shoots may be trained and pruned yearly just on my alternating principle—that is, one shoot to bear fruit and another to produce wood alternate with each other.

The next best mode is that called *spur pruning*, which some cultivators perchance would like to try. It is almost as simple as the other. Furnish the wall with upright or horizontal shoots, and prune in annually the laterals (which should not be left too numerous) to a single eye or bud. When these buds break they should be all trained on the upper side of the branch (fig. 7) and not pointing upwards, but rather aslant so as to allow the bunch to hang clear of the stem that bears the fruit.

Fig. 7

The summer treatment of Vines on walls consists in stopping the fruit-bearing laterals one joint beyond the bunch, and stopping also the side laterals at the first joint. This stopping must be persevered in all the summer. Each lateral that bears fruit

should be fastened to the wall in its early stage, in order that it may not be broken off by the wind or its own weight. Then, again, never allow more than one bunch to a shoot, and thin them moderately, to allow the berries that are left room to swell. Should the season prove a dry one, then give the border a good watering once a-week, and every third time water with liquid manure of a moderate strength. Syringe the Vines as soon as the fruit is set to keep the leaves clear of dust. Do this in the evening, then the leaves and fruit will get dry before the sun has any power to injure. Cease syringing as soon as the Grapes begin to colour. Of course, in dropping or rainy weather the syringing will be dispensed with. Should mildew appear, directly it is seen dust it with sulphur, which will check the disease if taken in time. When the fruit is all gathered, then cut off all supernumerary laterals and leaves, to allow the sun to reach the wall and heat it, and thereby ripen the wood.

One very important point the cultivator of the Vine must attend to, especially where the spur system of pruning is followed, and that is to carefully preserve the leaf nearest to the bottom of the yearling shoot. That leaf has to mature the bud that is to yield fruit the following season. If it is destroyed either accidentally or otherwise, it is ten to one if the shoot from that bud will produce any fruit the following season: hence that leaf should be carefully and sedulously taken great care of till it falls off maturely ripe.

Fig. 8 represents how a Vine should be pruned on the spur system. In four or five years the spur may become long and unsightly, but at its base there is always a knot of incipient buds, one or more of which, when the Vine is vigorous, will break. Such a bud should be allowed to grow and encouraged to acquire strength by hard stopping the leading shoot on the spur. In the autumn when the Vines are pruned the old spur should be cut off, and the young one made to take its place. By careful attention the whole of the spurs may be renewed and brought, as it is called, nearer home. My friend Mr. J. Meredith, of the Vineyard, Garston, near Liverpool, prunes his Vines still more severely. He cuts off all the spurs annually, and states that he very seldom fails having fruit from the incipient buds; but then his Vines are so extraordinarily luxuriant and fruitful that he can afford to (what I call) take liberties with them.

Fig. 8.

In wet, cold summers, however, the wood may possibly not get ripened to the full length of the yearling shoots to the top of the wall, especially in situations considerably north of London. In such a case (or indeed in every case for the Vine) I would advise the wall to be flued and heated either by the old method of common hot air, heated from a fire placed at the north side, or by hot-water pipes carried within the flues in the wall to the top, with returning pipes brought down again to the boiler. The advantages of hot-water pipes are, that the top part of the wall will be equally, or nearly so, as warm as the lowest range, which is not so with walls heated with the smoke or hot air in the ordinary flues. It is true the hot-water pipes are more expensive; and the other method, if well managed, is not greatly inferior, especially if the Kiddean system of heating the air so strongly recommended by my friend Mr. Beaton be adopted. In addition to this helping the Vine to ripen its wood by heating the wall, the ripening of the fruit will be assisted also. In unfavourable summers like that of 1860, if the cultivator has a few spare lights of glass at hand, he might with advantage make use of them by placing them against his Grape wall. Even covering each, or part of the bunches of fruit with bell or small hand-lights, would ripen the fruit better and sooner than if left fully exposed.

In order to facilitate the growth and ripening of both the wood and the fruit, early shelter from late spring frosts and cold winds, the Grape wall should be covered with netting of some kind. Much has been said in favour of tiffany; but though it has merits, yet, from its close texture, it excludes too much light and air. Woollen netting also holds moisture too long,

and contracts and expands according to the state of the weather. I have seen a kind of netting called Brittain's netting, that has the least objectionable points of any in my opinion, and being made of three-fold cotton it is strong and lasting. However, any of these kinds are sufficiently good for the purpose, and used early in the season, will help to bring out the young shoots earlier, and protect them from cold. Remove these shelters towards the end of May, they have done their due. In the autumn, if it should be cold and wet, then replace the shelters, for the double purpose of ripening the fruit and the wood.

The woodcuts also display how the side shoots or laterals should be trained so as to give the bunches clear space to swing, as it were, at their ease. In such an open position the sun will heat the wall in their immediate neighbourhood, and thus conduce to mature and ripen them better than if they were hanging close to the stems in a thicket of leaves.

If the above points of culture are carefully attended to, I have no doubt very fair Grapes in moderately favourable seasons will be brought to perfection even on open walls. And let not the cultivator of the Grape even in the north of England fear to try it on the open wall. I know at least two examples of successful culture in that way as far north as Yorkshire. One is at Temple Newsam, near Leeds, the seat of H. Meyrick Ingram, Esq., under the successful management of his excellent gardener, Mr. Taylor. The other is in the gardens at Swillington Hall, about two miles from Temple Newsam, Sir John Lowther's place, managed by Mr. Broome. Both are fine examples of successful culture of the Vine against walls in the open air. T. APPLEYBY.

(To be continued.)

FORCING.

(Continued from page 98.)

CUCUMBERS.

WHEN once the growing of Cucumbers in dung-beds is mastered, there will be no difficulty in growing them with the assistance of hot water or flues. When I could not grow them early in a Pinc-stove heated by flues, which used to give as many as I wanted in pots and boxes, I was forced to try to get them earlier in pits heated by hot water. These pits were deeply sunk originally, and pigeon-holed in the walls for dung linings; but as my employer neither liked the littery appearance of the dung, nor the idea of letting me have such a quantity of it, I obtained hot water as a substitute. The pits being so deep, a part of the bottom was filled in and rammed; open rubble was placed round the pipes for bottom heat, and these were covered with rough and then fine gravel. The soil was placed above. For early crops, however, nothing could be done without moving the sashes, which led to digging out the path, and building a four-inch wall there, so as to permit attending to the plants in all weathers by a small door in the back wall. Below the pipes for bottom heat, a layer of concrete is placed upon the rammed clay and earth, which sets sufficiently firm to retain a little water about the pipes and rubble when poured through a drain-pipe which is introduced through the soil down to the concrete. The only objection I have to such a pit is the small top room; for, though the space for earth is not 3 feet wide, that is generally earth enough to keep up great luxuriance in the plants. The front pipes for top heat, &c., are just near enough the plants.

What I should much prefer for Cucumbers in a lean-to house, would be a house like *fig. 40*, 8 feet wide and 11 feet high at back. I should have liked it better still 1 foot or 18 inches wider, 1 foot higher, and hipped roof at back of 18 inches or so, where air could be given, and all the front roof fixed. I have shown four pipes, one at front and one at back for top heat, and two below the bed for bottom heat. I would have these pipes on a level, the one at back and front flows, and the two beneath the bed as returns. There is the same concrete below the beds, and gravel on the top of the rubble, and means for pouring water into the rubble when deemed necessary. A strong flue might go through such a bed and return close to the back wall. The flue might go and return beneath the bed; but then there would need be openings in the pathway wall, or tubes through the bed to let the heat up. It will be seen how easy it would be to have either pipes or flue in a chamber, the earth being supported by a floor of slate, or stone, or even of wood alabs, with the interstices between them filled with pieces of brickbats and stones. Many like that system best; but I own I consider clinkers, brickbats, &c., with a fine surface, such as fine gravel, so as to get the earth

clean off, the cheapest, the easiest heated, and altogether the best *Fig. 41*, is a section of a first-rate Cucumber-house, 12 feet wide, inside measure, pathway 3 feet, side walls 3 feet, with moveable

Fig. 40.

glass sashes 2 feet, height to ridge 9 feet, ridge-board double, with wooden ventilators hung between, and a double ridge-board to prevent rain driving in, and yet allow air freely to pass. At

Fig. 41.

Luton Park a house is now building on a similar plan, but at least 3 feet higher, and the cowl itself sets close to the glass, and is elevated in pieces by a lever. The top heat and bottom heat are respectively under control. *Fig. 42*, is a much more

Fig. 42.

economical affair, and is, as far as I recollect, a section of a house used very successfully by Mr. Burton, of Hatfield House, both for Cucumbers and Vines in pots. It is a span-roof with no glass in the side walls, and two pipes on each side for top heat. Warm manure sweet, 2 feet or so in thickness, is placed below the soil to help to warm it at first, and the plants are turned out and answer remarkably well. The house faces north and south or nearly so, and were growing only on the north side at the beginning of May, and were very fine indeed. Even in winter I was assured they do well, as the four pipes keep not only the atmosphere, but the soil warm enough. Our readers may easily see how such a house may be varied as to its heating. For

instance: the heating-pipes might be below the pathway, and a drain-pipe would keep up a circulation in the house, and the two pits might be filled with hot leaves and tan, and plants be grown in large pots, and fresh tan added as needed, or a flue might go under the pathway instead of pipes. In such a house with a strong flue round one end and two sides, without any pits at all, fine Cucumbers could be grown in boxes 18 inches long, 18 inches deep, and 15 inches wide, set upon the top of the flue with just a piece of tile at each corner to keep the bottom of the boxes off the flue. On all spare spaces of the flue we would have evaporating-pans to use when necessary. With a flue half of it nearest the furnace brick on bed, and strong tiles for covering, and the house not more than from 25 feet to 30 feet long, and some 10 feet wide, I should desire no better means, though hot water is much less liable to accidents. In heating the soil taking care it is neither too hot, nor too dry, nor too wet, &c. The same minutiae must be attended to as in dung-beds; but Cucumbers in a house are always more interesting, as the fruit is always so much more handsome when seen suspended from a rod or trellis. There being so many inquiries as to different modes of growing Cucumbers will furnish a place for these remarks.

R. FISH.

EFFECTS OF POTATO STEMS BEING FROSTED.

IN answer to inquiries in your Journal of the 21st ult. Though your correspondent, under the signature of "THE DOCTOR'S BOY," has come to the conclusion that where the shoots have been repeatedly cut down by frost, as almost every one must have found during this spring, the crop at lifting time has not suffered, the difference will, I think, be perceived in the size, but not the number of Potatoes under the stems. This seems only reasonable to expect; for the largest Potatoes are lifted under a single stem, which has escaped frost: whereas, after having been once, or oftener, cut back by frost, it is invariably the case that numerous shoots are sent up, and the nourishment required for their support tends naturally to diminish the size of the Potatoes as a crop.—ASULEAF.

TORRY HILL.

THE SEAT OF LORD KINGSDOWN.

I HAD the good fortune a week or two since of having Mr. Newman for a guide in a walk through the grounds and houses of the above-named place, and who was very attentive and kind in pointing out to me those objects most worthy of notice, and from whom I gleaned the following particulars:—

Torry Hill is situated about a mile south-east of Milstead, in Kent, on an eminence 500 feet above the sea level, and is exposed to all the biting influences an inclement winter can bring; it is within the postal district of Sittingbourne, from which town it lies five miles south. It was held, prior to the present possessor purchasing it, by one of the Tylden family, a family of some note in this county as early as Edward III. The origin of its name I have not been able to obtain with any certainty; but it is probable it is corrupted from "Tarry Hill," thus intimating that the rambler is impulsively urged to tarry and admire the many and varied beauties surrounding him. The scene which struck the beholder when its name was given has not lost an iota of its grandeur since: on the contrary, the improvements which have been made in the immediate grounds affect materially objects in the distance. Whether in the early summer morn, when a vapour cloud floats between earth and sky, shutting from the view all objects save the tops of the Sheppy Hills; whether in the dewy eve, when the declining sun throws its weakened but glaring rays upon the swell of the far-off sea; whether, when the noontide heat gives even to the dull soil a glitter, painful for the eye to rest long upon; or, again, whether in the depth of the dreary winter, when the feelings are dull and dormant as Nature itself appears to be, it would be impossible for the beholder to gaze from here without unbounded and just admiration.

The most striking object is the Sheppy Isle, which is exposed from one extreme to the other. The Swale, it may be imagined, is no small feature in the scene. I stand on the terrace. Facing northward objects, between the points of Boughton Hill and Chatham, a distance of twenty-two miles, are easily pointed out. There, directly opposite, is the Ferry of Emley, where James II. narrowly escaped being taken when flying his kingdom, and would have been roughly handled but for the timely aid of the

powerful Sir E. Hales. There is the seat of the Cromers, and there that of the Hugessens. Yonder is Tong, founded, it is affirmed, by Hengist and Horsa. There is Teynham, too, of Saxon name, and many other places of historical interest fall beneath the eye; and the whole expanse south of the Swale is composed of rich and well-tended land, interspersed with considerable tracks of woodland.

I now come to the house and grounds. At the time when Lord Kingsdown (then T. Pemberton, Esq.) took possession of the estate, both house and grounds were small; but they have been gradually extended, and at the present time both are noble in appearance and extent. The park contains 350 acres, and is well wooded. Some extensive tracks of woodland are being grubbed in and adjoining it for general improvements. The house stands in the midst of grounds well laid out, and has lately been restored, being built of red brick and white stone. The east front is approached by a carriage drive from the park, and also from the high road south of the mansion. At the entrance door is a noble portico, over which, immediately under the eoping and carved in stone, are the arms of his lordship. At the north-east angle is an octagon tower, 80 feet high, the whole of which is covered with Portland cement. Passing along the north front we came to the conservatory—a square building with glazed roof, and large lights in each front facing north and west respectively. The angles are of solid masonry, corresponding with the main building. At the south of the building are the servants' offices, which appear to be ample and very convenient.

Plants—Conservatory.—In speaking of the extremely fine collection of plants, I begin with the conservatory. This building is entered from the house from the drawing-room, and also from the saloon; the latter being very lofty, and both most elegantly decorated. On the left side of the conservatory from the saloon entrance is erected a stage, which was very gay with Cinerarias, intermixed with Tulips, of which the double Tournesol and the scarlet Van Thel were very conspicuous; there were also *Salvia gesneriifolia*, *Dielytra spectabilis*, some *Tropeolums* trained to larch fir tops, *Epacris*, *Coronillas*, *Gernistas*, *Camellias*, and many others, the whole producing a charming effect. Standing in pots in a border opposite were some *Azaleas*, and *Roses*, and a *Tropeolum* trained to the shape of a crown, and full in bloom. In the bed stood a fine specimen of *Stenocarpus Cunninghamii*, 12 feet high, a size rarely met with in this country. On either side from the drawing-room entrance were two magnificent *Orange* trees looking in perfect health: near them was a noble plant of *Araucaria excelsa*, but unfortunately it has lost its leader. Running up iron columns, and from which its flowers hung in graceful clusters, was the old and (for conservatory) valuable climber, *Clianthus puniceus*, there were many other climbers and scarlet *Geraniums* trained up the columns; some of the *Geraniums* were 14 feet high. In the borders *Camellias* were planted, which were in bloom, and of various colours, and some reaching a height of 10 feet. High amongst them was a plant of *Pittosporum tobira*, with a cream white flower, deliciously fragrant.

Lawns.—Leaving this building by the west front, large masses of *Azaleas* and *Rhododendrons* were brought fully before us, and many *Coniferous* shrubs and standard *Rhododendrons*; amongst which *Picea Pindrow* was looking very well. These beds of shrubs are sheltered from the west by a belt of *Firs*, with some fine large trees of *Ash* and *Elm*, giving the whole a forest appearance. On the north front of the conservatory and mansion is a terrace newly made, 290 feet long and 10 feet wide; and below this is a flower garden, laid out this spring, from the design of Mr. Fox, the gardener. At the west end of this is a spreading *Horse Chestnut* tree, whose under branches sweep the ground, the tree taking the form on a gigantic scale of the bunches of blossom it bears. Fronting this garden is a wall built on a level with the surface, topped by balustrading, and this again ornamented with vases. Moving to the east front we crossed the drives already mentioned, and where stands a lengthened grove of lofty *Scotch Firs*, at the end of which, near the park entrance to this lawn, were several more large beds of *Rhododendrons*, the scarlets breaking into bloom. The plants on this lawn were very fine, of which I shall mention a specimen of *Cedrus deodara*, 30 feet high, *Araucaria imbricata*, and the *Wellingtonia gigantea*. This last was 6 feet high, and 13 feet in circumference, was looking rather brown, but showing every sign of starting. *Cupressus torulosa*, *Pinus excelsa*, and many other ornamental plants with those I have before named, appear to have stood the late winter well, which is somewhat astonishing, situated as Torry Hill is, and exposed to the cold north winds, and with a soil of clay full

of flint; but it must be stated, that when planted Mr. Fox took great pains in preparing the ground for their reception. He had large holes made, and filled with a made soil, suitable for them; and their now flourishing condition amply repays for the care at first taken.

Houses.—Passing through a curved walk we came to a large dome, 20 feet high, which stands in the centre of a range of houses 160 feet long. Under this dome is placed a large cistern, the water from which forms the chief supply for boilers and watering the houses; in this, too, are kept a number of golden and silver fish. Some pyramidal Fuchsias of great height stood here, and were breaking into blossom from the bottom to the top, and will, in a short time, have a pleasing effect. A monster Tom Thumb Geranium was prominent; in two years it has made astonishing growth, being fully 10 feet in circumference. On the left was a vinery which appeared in a fair way of producing an abundant crop. Arranged on shelves were many young Fuchsias and Azaleas, which had done blooming, and some large plants of *Lagerstrœmia indica*, now generally little thought of. Entering the house adjoining (which was once a conservatory, but now converted into a vinery with a large Pine-pit in the centre) we found numbers of succession plants, which, in the winter, are removed to pits heated with dung to give the Vines a rest. The Vines will have been planted three years next June; they are planted inside the house, and are very vigorous, producing last season canes 2½ inches in circumference. In December they were cut back, leaving six eyes to break, which now have pushed out shoots, very strong, showing two or three bunches on each lateral; but it appears the gardener intends leaving only one bunch on each, and from three to six on a Vine. The leading shoot, which will not be stopped for some time, has already, since March, attained the length of 10 feet, and is 2 inches round. All the laterals are stopped one joint above the bunch. The Golden Hamburgh and Bowood Muscat were amongst the sorts grown. Round the house were shelves filled with Strawberries in pots. My attention was taken by some standard Geraniums (scarlet) 5 feet high, and trained to a circular head. In front of these houses was a range of cold pits, containing several thousands of bedding plants, intended for the garden before named. At the back was what was termed a "cold house," in which were many Heaths coming into bloom, and a number of specimen Geraniums in very good condition, well set for bloom, and not a spot or disfigured leaf about them; there were also some fine seedling Calceolarias, and many New Holland plants. A glass-roofed potting-shed joined this, which was light and conveniently fitted. Again entering the dome, and turning to our right, we entered a large Pine-stove, in which were Pines in excellent condition; some ripe, and others fast approaching ripeness. On shelves close under the glass were some very large Strawberries (Keens' seedling); also Dwarf Kidney Beans in abundance. Further on we came to the Peach-house, where there were trees trained up the back wall and roof. In the centre was fixed a large slate bench, upon which were fruit trees in pots; the Peaches were looking remarkably healthy and covered with fruit the size of walnuts. All the trees are managed on the spur system, and some of them were old trees taken up and replanted last February twelvemonth, but bore an excellent crop of fruit last season, some weighing 11 ozs. Here, too, were seedling Calceolarias on slate, near the front lights. Slate is used in most of the houses, and is found to answer well with all kinds of plants. Leaving here, opposite was a stove with a dome in the centre; on opening the door, directly facing us in a bed of soil, was the *Brugmansia suaveolens* with its beautifully white blossoms. This magnificent plant originally stood in the conservatory; but as it did not do well there, it was moved to its present situation, and has not only made a rapid growth, but flowers profusely, having blossomed freely and continuously since last November. In the same bed stood the rarely-seen plant, *Strelitzia regina*, profuse in its beautiful purple and orange flower; there were also *Thyracanthus Schomburgkiana* with its long pendulous racemes of scarlet flowers, and a strong plant of *Musa Cavendishii*. From the roof were suspended many Orchids, and in bloom, one worthy of notice being the pretty *Dendrobium pulchellum* in a mass of bloom. Under these were some fine Ferns and Selaginellas; and in other parts of the house were Cactuses and Gloxinias in bloom, and many of the Begonias—one very pretty—*Begonia Marshallii*; there were also some Caladiums, such as *Chantini* and *argyrites*, and other fine-foliaged plants, including *Cissus*, *Dracæna*, *Maranta*, *Farugium grande*, &c. At the end of this stove was a hollow wall, 200 feet long and 14

feet high, and covered with healthy-looking Peach and Nectarine trees, but not having much blossom, which is the general complaint this season. Crossing the road which leads to the back of the mansion, we came to another wall, 100 feet long, and covered with glass, on which, too, were Peach and Nectarine trees with fruit well set. The trees appear to have greatly suffered before being covered in, but there is every prospect of their recovery. Some Fig trees were covered in the same way, and showed well for fruit. At the back of this is a Mushroom-shed, 40 feet long, and heated by flues; it affords a good supply, and one bed at the time of my visit was very full.

In closing, I must say I was much gratified with everything shown me, and which reflects great credit on Mr. Fox and Mr. Newman.—F.

GROWING MELONS IN POTS.

THIS subject may be alluded to at greater length ere long, but to meet the inquiries of a correspondent ("N. D."), we will shortly state—

1. That Melons may be grown in a greenhouse from July to October, and without any bottom or other artificial heat; but only well if they have the greenhouse either to themselves, or have such plants as neighbours as would stand a rather close, moist heat when growing. If the house was kept airy enough and cool enough to keep *Pelargoniums*, *Fuchsias*, and things of that sort in sturdy vigour, then Melons would have a struggle to do well, and could only be expected to fruit well in a fine, sunny season. Otherwise if a house can be closed early in an afternoon, and only a little air given early in the morning, but when the plants are growing freely not a vast deal given during the day, the Melon will grow under glass alone for the time specified, and rather better in a pot than when planted out, as its natural luxuriance will be moderated.

2. We have had nice fruit from eight-inch pots, extra well attended to with manure waterings, but, in general, we prefer the pots to be fourteen or fifteen inches. We then prefer a plant that has been stopped at the rough leaf, and one shoot selected and tied to a little stick, and all the other buds nipped out. We would shift this plant from a 60 and a 48-pot into a 32, and then when getting full of roots transfer the plant at once to a fourteen or fifteen-inch pot, using rough, stiff mould, sometimes alone and sometimes with a little leaf mould, and we think the plants do as well with the rough soil alone. This is used neither wet nor dry, and squeezed lightly round the ball. If the soil is so stiff as to have a portion of clay in it, and thus might be apt to crack in a sunny day, we used either to put a little moss on the surface, or a little rough leaf mould or decayed dung, just to prevent the sun drawing the soil from the sides of the pot. When we were forced to use rather light, sandy soil, we have mixed a little leaf mould with it, and used it rather damp than otherwise, and beat it round the balls and the sides of the pot with a wooden pestle. I say used, because for two or three years I have had less room for this kind of culture; but previously I have adopted it wherever there was a spare place in a house, sometimes training the plants to a stout stick, sometimes setting them on the floor of a house and training them to a string fastened to the pot and the rafter above, and sometimes to a trellis in a pit in the usual way, and, however done, have had less trouble in pruning and better fruit as respects quality, because, so far as I am able to judge, the check given to mere luxuriance threw more of the sap of the plant into the fruit. Well, being thus potted, watering was given with some care, so as not to greatly saturate the soil with moisture before the roots were taking possession of it. As the shoot grew all the buds appearing at the axils of the leaves were removed, until the plant was 2 feet or 3 feet in height, according to the room that could be given it. The point of the plant was then nipped out, leaving four or six joints below it from which the buds were not removed. These soon throw out shoots, generally showing fruit at the first or second joint, and the process of stopping must be attended to as alluded to the other week.

From two to four fruit is a fair crop. We prefer the plants to be trained upright or to a trellis, though we have had good crops from pots, the pots being sunk in a bed, and the plants trained over the surface in the usual way.

Guano will do the plants good, especially if not used strong—say two ounces to a four-gallon pot; and top dressings of rotten dung too, will be useful—in fact, we prefer this rich manure watering to incorporating anything rich with the soil,

as there is less danger of cankering at the collar of the plant. We found it also advisable to have a small mound round the collar, and another small mound round the side of the pot; the latter not only tended to prevent the soil cracking there, but the water being poured in a shallow trench between the sides of the pot and the collar of the plant, the latter was not easily wetted, and the moisture could not escape by the former without wetting the earth in the pot thoroughly and regularly. As the fruits approach ripening, the pots would be better if plunged,

or half-plunged, or covered with mat or calico, &c., because too much dryness then might be hurtful, and too much moisture would be apt to militate against flavour. Except at that period I would as soon have the pots stand exposed as not. Though thus recommending chiefly pure loam and manure waterings, instead of rich soil at once, we hope if our correspondent tries the pot culture, he will not use guano, or hen-dung, or even fresh deer-dung, so strong as to kill or injure the plants. It is best and safest to use it weak and often.—R. F.

SIX WREATHS OF FLOWERS.

WREATH THE THIRD.

"What fashion will you wear the garland of?"—SHAKESPEARE.

FIRST bring ARISTOLACHIA PICTA, the plant, unbrittle stem of which is a choice foundation for any wreath or garland. In plain English it is "The Painted Birthwort," belonging to the natural order Aristolochaceae, or Birthworts, and to Gynandria Hexandria of the Linnæan system. This is a very handsome twining stove plant. Stem round and smooth; leaves deeply cordate, acute; flowers purple, and so tessellately marked with golden lines as to merit the

specific name "picta." The flowers proceed from the axils of the leaves, their limbs are about 3 inches long, terminating in a short, slender tail, and being deeply cordate at the other extremity; the mouth of the bent and contracted tube is marked by a large, oblong, yellow, blotch. It is a native of the Caraccas, from whence it was sent to Berlin in 1847, by Dr. Karsten. M. Van Houtte states that it requires all the heat and light we can command; for in the plains of which it is native, the unshaded day temperature is often 167°; but the vicissitudes it endures are great, for at night, when the sky

is cloudless, the thermometer sinks to 59°. The roots, however, in a soil covered with dead leaves, are not subjected to such variations of temperature, and the rain which falls is warmer than the air at the time. Van Houtte noticed that the rain was 78½°, whilst the air was not quite 75°.

Next let us have SPIREA DECUMBENS, a neat, pretty, hardy plant from the mountains of the Frioul, in Illyria, ornamental for our borders, and well adapted to grow on rockwork. It belongs to the natural order Rosaceae, and to the Linnæan class and order Icosandria Di-pentagynia. It has weak, trailing, tufted stems, rising about a foot from the soil; branches numerous, brown, and shining; leaves obovate, or oval, long-stalked, unequally serrated, entire near the base, green on the upper surface, but glaucous underneath. The flowers are numerous, in little terminal corymbs, on the young shoots; petals five, white, with a rose-coloured eye, and sweet-scented. It blooms in May and June.

Lastly, for to-day, add PONTHEIVA MACULATA, a curious terrestrial Orchid from Silla de Caraccas in the province of Merida, where it is found at an elevation about 7000 feet above the sea. Although it grows in soil, yet it is also found upon the trunks of old trees in the forests. In height it varies from 8 inches to 12 inches. The whole plant is clothed with glandular hairs. Two or three leaves first appear above the surface, and from among them arises the flower-stem, or scape, terminating in a loose raceme of small curiously-shaped and oddly-coloured flowers. The colour in one part of the flower is light ashy grey, dotted with brownish-red, and in another part yellowish, streaked with purplish-red. It blooms in February. A very good idea of the plant may be obtained from the coloured drawing of *Ponthieva petiolata*, in the "Botanical Register," ix. t. 760.

POMOLOGICAL CLEANINGS.

EARLY STRAWBERRIES IN FRANCE.—On the 18th April I gathered the first ripe Strawberries, May Queen, from the open ground about 6 feet off a south wall. They were delicious. On the 21st, Princess Frederick William alongside of May Queen commenced ripening; whilst Black Prince, also in the same situation, will require a week yet before fit for use. Under glass May Queen proved again to be a valuable variety for early forcing, and produced as usual a very abundant crop. Oscar was very good, and is, perhaps, the most solid and firm of all kinds. It will consequently bear carriage better than most sorts. I had six pots each of Highland Mary and Richard II., but,

alas! they were scarcely eatable, being exceedingly sour. They might do in the room of Gherkins, and would in that case require but little vinegar. Ingram's Prince Arthur is very fine, both as regards shape, colour, and flavour. Carolina superba, and Sir Harry, were, as usual, exceedingly fine. Two new kinds of Mr. Nicholson's seedlings, called Orb and Garibaldi, are very promising, and deserve to be extensively grown. Stewart and Neilson's Prince Alfred is very large and handsome, but a little woolly, though of nice flavour.—FERDINAND GLOEDE, *Les Sablons, near Moret sur Loire (France)*.

GROUND VINERIES.—It has often been said "there is nothing

new under the sun," and our daily experience assures us of the fact. Training the shoots of Vines along the ground, was recommended by Vispre in his "Dissertation on the Growth of the Vine," published in 1786, and was practised by him on a small scale at Chelsea, where "the Grapes were considerably larger than those of the same kind growing on a south wall and well ripened." He also states that Rev. M. Le Brocq had taken out a patent for training fruit trees in this manner. Speechley says, "Fruit trees of various sorts have been so trained at Welbeck for fourteen years." Even the great Lord Bacon suggested this method of growing Vines. He says, "In some places these Vines are suffered to grow like herbs, spreading upon the ground, and the Grapes of these Vines are very large."

SPROUTING ONION SEED.

"How is it you raise so large and nice Onions?" I asked of an Iowa farmer, as I was sitting at the table with him, and observing some on the table.

"Well," said he, "we sprout the seed with boiling water, and then plant it early and in good ground."

"Sprout the seed in boiling water!" I exclaimed inquiringly. "What do you mean, sir, by that? Won't boiling water kill the seed?"

"Not at all," he replied, "but it will sprout them in one minute's time."

"It will! It looks incredible!" I replied, with surprise.

"Well, you try it," he replied, grinningly, "when the time comes to plant, and you'll find it just as I tell you."

And sure enough, when spring came, and my neighbour was about planting his Onion seed, and being present, I said:—

"Jewell, last winter, there was a man told me in Iowa, that to pour boiling water on black Onion seed would sprout it in one minute. Suppose you try?"

"Very well," said he. And taking the tea-kettle boiling from the stove, he poured the water thus boiling on the seed, which he had in a tea-saucer. Looking at it for a moment, he exclaimed, "My conscience! you have told rightly. Only look there!"

I looked, and behold, the little sprouts, about as large as horse hairs, were shooting out of the opened ends of the seed! He did not retain the water on the seed above three seconds, and in less than one half minute after it was poured off, the sprouts were projecting from the seeds.

My Iowa friend assured me that this process would advance the growth of the Onion from two to three weeks beyond the ordinary method of planting without sprouting. Try it, gardeners and farmers; much may be gained by it.—(Correspondent in *Dollar Paper*.)

ENTOMOLOGICAL SOCIETY'S MEETING.

THE May Meeting of the Entomological Society was well attended, the chair being occupied by the President, J. W. Douglas, Esq. The donations to the library consisted of the recent publications of the Linnean, Royal, Zoological, and other Societies, and various periodical works, together with an interesting memoir recently published by Miss Staveley, containing an elaborate account of the microscopic structure of the apparatus by which the two wings on each side of the body of insects are kept together during flight, and which consists of a series of minute hooks along the fore margin of the hinder part of the wings.

Mr. Andrew Murray, the new Assistant Secretary of the Royal Horticultural Society, was elected a member of the Society.

Mr. Stainton exhibited some leaves of the Birch, each containing a minute mining Caterpillar, which had recently been discovered to belong to the genus *Micropteryx*, a group of very interesting minute Moths of rather doubtful position in the system, whose economy had hitherto remained problematical. They are entirely destitute of legs, with the body gradually tapering to the tail; and they have the peculiarity of ejecting the excrement continuously, so that it forms when dry a thin black thread within the burrow of the leaf. He also exhibited the larva of *Antispila*.

Mr. Samuel Stevens exhibited recent specimens of the very rare *Saperda oculata*—a handsome Beetle formerly taken in the Fens of Cambridgeshire, but which had been supposed to have become extinct. Also, some rare Beetles of the families *Cetoniidae* and *Paussidae* from Africa and India.

Dr. Power exhibited specimens of a new British genus of Hemiptera, being the *Micropus sabuleti*, belonging to the family Lygaeidae, taken at Merton and Folkestone. Mr. Wollaston had also found it in Dorsetshire.

Dr. Wallace exhibited a specimen of the Indian Death-head Moth (*Acherontia Lethe*, Westw.), which had been taken alive by a lady at East Cowes.

Mr. Hayward exhibited *Eurypterus picipes*, taken among dead leaves at Sanderstead. And Mr. Machu various rare species of small Moths of the genera *Coleoptera* and *Gelechia*.

Dr. Wallace congratulated the Meeting on the recent establishment of a Professorship of Zoology, by the Rev. F. W. Hope, at Oxford, and the nomination of Mr. Westwood thereto. He felt convinced that in the hands of that gentleman the progress of the science of entomology would not be neglected.

Professor Westwood explained the reason which had led to the postponement of the course of entomological lectures which he had announced—namely, the necessity for the removal of the Hesperia Collections to the new museum recently completed at Oxford.

An interesting memoir by T. V. Wollaston Esq., was read on the species of *Coleoptera*, which inhabit the Euphorbiaceous trees in the Canary Islands and Madeira. He had been led to believe that that portion of the vegetation of any place which was more especially peculiar thereto, would be most probably productive of the most characteristic of its insect inhabitants. He had accordingly carefully examined the Euphorbiæ on the islands in question, where they grow to the size of trees, and had found that, although their leaves were comparatively free from the attacks of insects, not fewer than forty-four different kinds of Beetles attacked their stems, especially in a decaying state, and that, too, often in perfect myriads. Of these forty-four species, thirty-two exclusively confined their attacks on the Euphorbiæ; the other twelve were, however, occasionally met with on other trees. In Madeira the Euphorbia had been nearly destroyed by the inhabitants, so that he had only found eight of these Euphorbian species in that island, which originally was almost covered with groves of that tree. It was, therefore, evident that in this instance, from the careful manner in which he had investigated the Coleopterous productions of Madeira, the species of Beetles originally intended by Nature to subsist on the Euphorbiæ had not been able to modify their habits and transfer themselves to a fresh kind of food, but had died out with the trees themselves. As might be expected, amongst these Euphorbian Beetles were several new genera.

Mr. F. Walker communicated a paper entitled, "On the Distribution of Insects in the Channel Islands of 1860;" but it consisted simply of an account of the topography of Jersey, with a list of the species of Spiders found in that and the other islands.

Dr. Knaggs exhibited and explained a novel kind of breeding-cage which he had invented for rearing insects. It consists of a wide glass cylinder (the bottoms of glass shades cut off in the glass warehouses), the bottom of which stands upon an unglazed plate, in the centre of which is a hole, through which the stems of the food plants are to be stuck. The top of the cylinder is to be covered with gauze.

WORK FOR THE WEEK.

KITCHEN GARDEN.

EMBRACE the first opportunity afforded by the ground being moist for thinning Onions, Carrots, Parsnips, Turnips, &c. Let the hoe be run through the crops sown in drills, not merely skimming the surface of the soil, but moving it 1 inch or 2 inches in depth. This, while it destroys the weeds, at the same time pulverizes the soil and checks rapid evaporation. *Broccoli*, prick out any that is sufficiently advanced in growth. Sow a full crop of Cape and Grange's Early White. *Cardoons*, sow a late full crop. *Celery*, plant some of the most forward into trenches. *Cabbage*, sow a little seed for autumn produce, any of the small sorts to be preferred for this sowing. *Cucumbers*, peg down the plants in the ridges as they advance in growth. *Onions*, after thinning loosen the soil between the rows; and if the weather is dry give them a good watering. *Peas*, the last sowing of Knight's Dwarf Marrow to be made, as it is longer in coming into bearing than any other. *Radishes*, make another sowing of the various sorts. *Mint*, make new plantations. Draw the young suckers by hand; top, and plant them 6 inches apart. *Scarlet Runners*, stake, after drawing a little earth to them with the hoe.

FLOWER GARDEN.

The bedded-out plants to be duly attended to with water in dry weather until they begin to make fresh growth; but with the present favourable weather and proper attention they will soon cover the beds, and will repay all the trouble and attention paid to them; but if through inattention they are allowed to get into an unhealthy state at present there will be some difficulty and much loss of time in getting them into free growth. Make a full sowing of Brompton Stocks and all biennials for flower-garden purposes, and a successional sowing of some of the most showy annuals for autumn blooming. Gather seed of Auricula as soon as the seed-vessels appear brown, and before they open. Continue to propagate Chrysanthemums by taking off the tops, and sticking them under a hand-glass on a shady border. Cut back those intended for specimens into proper shapes; if cut flowers are wanted, do not take off the tops, however straggling the branches grow. Dahlias planted out and making growth to have three or four stakes round the centre to support the side branches as they grow. Take off side shoots from Pansies and from double Wallflowers, and strike them under a hand-glass on a shady border. Hollyhocks to be staked, tied, and attended to as they advance in growth.

FRUIT GARDEN.

When the Strawberries are set give them, if the ground is not very rich, a good soaking of liquid manure. Still watch for insects of all kinds, and follow up continually all disbudding matters. Pick grubs off Apricots, Pears, and Plums; they are generally to be found in curled leaves, and the caterpillars of the lackey moth in groups. Thin the shoots of the Raspberries to two or three of the strongest, if not already done.

STOVE.

Let rambling shoots have frequent stopping. Shift Clerodendrons, Erythras, Gloriosas, &c., and give liberal supplies of weak manure water to plants in robust health. Stove plants that have arrived at a certain and required development may be removed to adorn the conservatory, and to prevent them breaking into unnecessary growth. Orchids will now require frequent waterings and syringings, especially the *Erides*, *Dendrobiums*, *Phalenopses*, *Saccolabiums*, *Vandas*, and *Sobralias*. See that the baskets containing *Gongoras*, *Stanhopes*, *Peristerias*, &c., are well saturated when they are full of roots.

GREENHOUSE AND CONSERVATORY.

Do not delay any longer to place the young growing plants of Heaths and other such hardwooded plants in a spare pit where the lights can be readily removed, to take advantage of dews or light showers, and the shading, which will sometimes be necessary, can be easily removed; the pots to be plunged about half their depth in cinder ashes. Examine them frequently for mildew, and apply sulphur the moment it is perceived; some of the softwooded varieties of Heaths being very liable at this season to be attacked by that pest. Common and fancy *Pelargoniums* for late blooming will thrive well in a cold pit, where they can be protected from heavy rains. *Kalosanthes* (*Crasulas*) to be trained neatly, and watered with liquid manure occasionally. Train *Fuchsias* in the desired form, and pinch back weak and straggling shoots. *Rhododendron arboreum* and its varieties should be fully exposed to the sun under glass to have perfect foliage and an abundance of flower-buds. Partial shading is their ruin as regards their foliage and the forming of their flower-buds.

FORCING-PIT.

This pit may now be profitably filled with plants requiring the aid of additional warmth to bring them kindly into bloom; among these may be classed Cockscombs, Balsams, Hydrangeas, Gardenias, &c. The propagation of *Pelargoniums* may also be carried on at the same time in this pit, as well as many kinds of softwooded plants.

PITS AND FRAMES.

Shift and attend to such plants as are intended to form specimens; sprinkle with water, and shut up closely late in the afternoons of hot days. Put in cuttings of choice herbaceous plants, in order that they may be rooted before the pits or frames are again wanted for cuttings, to supply the flower garden next year. Continue to repot tender annuals as soon as they fill their pots with roots.

W. KEANE.

DOINGS OF THE LAST WEEK.

STILL no rain, though showers are heard of. Dug ground for succession garden Beans, Dwarf Kidney Beans, and Peas, drawing out the drills of the taller hollow, to permit of a good watering without covering the seed much. A friend covered some 8 inches deep two months ago, to save all earthing-up, and succeeded certainly; for there will be none to earth, the Peas having already resolved themselves into their primitive elements. Hoed the ground amongst Sea-kale, Artichokes, and Asparagus, the latter getting overrun with the *Convolvulus sepium* (Devil's Guts the men call it) the smallest bit of which will grow, but which frequent cutting will kill by exhausting the roots. Last season we had a piece of ground of which it took entire possession; and as it was small we let it alone to grow rank and luxuriant; cut it then with an old scythe; cut it a second time; and then, cut it with the Dutch hoe every time a bit appeared; and on digging it this season, scarcely a bit of white root was to be seen, though, previously, every spadeful of soil would be a mass of white roots. I once tried another plan with a bad piece—covered the ground with 15 inches of short grass from the lawn, the heating of which did for them. It is one of the worst things in a garden to eradicate; Twitch and Dandelion are nothing to it. Will cease cutting beds of Asparagus intended for forcing—in fact, do not cut them much; will give a little salt as soon as there is the appearance of rain. Sowed more Turnips and Radishes in alternate rows, watering the seed in the rows with a rose of a watering-pot before covering. In such dry weather do so with all seeds in the open ground. Dug over ground for winter Greens, to be ready when rain comes. Cut off the flower-tops of Brussels Sprouts and Scotch-kale, to afford, along with Spinach, a few dishes of nice greens before the Cabbages are well hearted, when all the stumps will be removed, and be burned, or rather charred. Watered Cauliflowers to prevent them standing still. Staked Peas, sowed Spinach between them, and thoroughly cleaned and hoed Onions, Carrots, Parsnips, &c., waiting for rain to enable us to thin them easily.

Ran the hoe again through Strawberry-beds, which are crying out for a good rain to enable them to swell and set their fruit nicely. Have long noticed that a fine shower when Strawberries are in full bloom seems to help the dispersion of the pollen rather than otherwise, and hence frequently imitate it in fine sunny days with plants when in a forcing-house. Covered a border with sashes to hasten maturity. Keep thinning out of the houses as room can be found for them in pits and frames, though having merely the protection of glass, as they will be better flavoured than when in shady houses. Syringed, disbudded, and destroyed insects on Apricots and Peaches, shortening or removing strong shoots that would act as robbers to the rest, and be of no use afterwards. On young trees shortened the side shoots of Cherries, Plums, &c., by nipping off their point, and allowing only the leader to grow. Gave the first nipping to dwarf Pears and Apple trees; the latter showed well for bloom, but were terribly injured by an army of Tomtits, that did great destruction in a single day, clearing off some trees entirely of their blossom-buds before they were noticed, and departed in a few days after the poor compensation of leaving some scores of their bodies behind them as the result of shooting and trapping. Caterpillars are more numerous than usual this season on Pears, Cherries, &c., and it is a nice job for boys to pick and squeeze them. On a few Gooseberry trees in an orchard-house the caterpillar appeared, and still more on a few Currants, both of which we wanted early for tarts; but in the open air all seems right as yet, but as a preventive will give all the bushes a good scouring from the syringe of lime and soot water clear, made by placing a bushel of soot and half a bushel of lime in a hogs-head-barrel, and using it when it had cleared twenty-four hours after being made. This will be acrid enough to make the caterpillars drop if there should be any, and the back of the spade will soon settle them. Engined Morello Cherries just set and setting with a weak solution of Gishurst, the men liking it just as bad as the strong solution of lime and sulphur and a little soft soap, long used and several times described, and which they declare it much resembles—at least, the smell is much the same. The removing of the smell as spoken to the other week will be an advantage, if the insects like it as bad in the sweet state, of which I am as yet rather doubtful. Watered, stopped, and regulated Melons, giving the ripening fruit plenty of air, and keeping the surface of the soil dry. Watered Vines in pit for about the last time before the fruit will be cut. Thinned fruit

in second house, the last just coming into bloom, kept at from 63° to 68° at night, and when fruit is set, especially Muscats, will lower the temperature a little. Earlier houses are allowed to have the laterals pretty well untouched, to encourage root action to swell off a very heavy crop, and as they approach maturity the laterals will be thinned by degrees. Kept syringing the Peach-house to keep down red spider, as that will soon have to stop as the fruit is ripening. Gave plenty of water to Figs, and air early, as dryness will be apt to make them drop, and a close moist atmosphere with the sun strong on the house will be apt to parboil them at the points, and then they will begin to decay and rot, instead of swelling freely and ripening kindly. Whether planted out or in a pot, if well drained to prevent stagnant water, it is next to impossible to over-water Figs when the fruit is swelling freely. When at rest the roots should be dryish, not dust dry. Even when swelling, stagnant water at the roots will cause the fruit to drop. When pots, therefore, are set in saucers, the water in the saucer should not long be above a quarter of an inch deep, and then that will be considerably below the drainage.

Amongst plants, Gloxinias, Caladiums, &c., have been shifted. Azaleas, forward ones for want of a better place have been placed out of doors, with a little Nottingham netting over them. Ditto some large hybrid Rhododendrons. Cytisus, &c., have been placed in a similar place from the conservatory, after being well syringed and slightly pruned. Pelargoniums have been trained; tied out when necessary. Cinerarias mostly removed, and the places supplied with Fuchsias, scarlet Geraniums, &c. Means will be taken ere long to grow on a fresh stock for succession. Watered creepers planted out in conservatory. Shifted Ferns and Achimenes; but was chiefly engaged in bedding out, all of which work would have gone on more smoothly could we have calculated on a little shower now and then; but the plants stand better than could be expected—the annuals transplanted from a bed, as previously noticed, showing no signs of flinching, and their straight lines and even beds will be procured with more certainty than from sowing, more especially when water is such a scarce commodity that watering such seed-beds could not be thought of. We have thus, among other things, planted out two large beds of each of the two *Corymbes*—*atro-sanguinea*, and *Drummondii*, and we have strong confidence that few of our best things will present a better mass of continuous bloom, though any one that could give a little trouble might have such beds at the expense for seed of some six pennies, less or more. Another old-fashioned favourite of ours, for beds or rings, is the yellow Hawkweed, which, so treated, will generally present a mass of light yellow from June to November, and about a foot in height. The *Saponaria calabrica* for low beds and belts, and the *Chrysanthemum tricolor* and aureum, and the varieties *Burridgeanum*, make nice lasting beds, 18 inches high, and so do the new varieties of *Dianthus laciniatus* and *Heddevigii*, about a foot high; but these should be pricked out separately, and protected before final planting. We have just used them as an edging for *Phlox Drummondii*, their stiff habit will make a sort of fence for the *Phlox*. Beds of the best varieties of the above *Phlox* will generally stand well from seed sown in a little heat, pricked off; and then, after being grown and hardened off, planted out. The finest kinds raised from cuttings are very apt to give way just about August. The same thing sometimes takes place with *Petunias* raised from cuttings, and they must be so raised to secure the same shade of colour; but seedlings seldom give way before the frost comes.—R. F.

TRADE LISTS RECEIVED.

General Spring Catalogue for 1861, of William Cutbush and Sons, Highgate.—This is a good catalogue of bedding things; besides which, we observe lists of Azaleas, Gloxinias, Ferns, Dahlias, *Phloxes*, *Pelargoniums*, &c.

A List of Select Plants by F. & A. Smith, Park Road, Dulwich, S., 1861.—An excellent catalogue of what is called soft-wooded and bedding plants, for the extensive cultivation of which Messrs. Smith are so well known.

Catalogue of Geraniums, Fuchsias, &c., by Edward Taylor, Malton, Yorkshire, 1861.—A well-got-up and spirited catalogue of softwooded plants, the contents of a country nursery, which appears to keep pace with the times.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

VARIOUS (*K. E. T.*).—Mr Roberts has never written but one book on the Vine, and we are unacquainted with his present address. We believe he has retired from the gardening profession. Leave the shoots of the Asparagus to seed, and cut them down when they begin to die off in the autumn. The best substitute is leaf mould, which is, as you perhaps know, decayed leaves, wood, and other vegetable matter. This mixed with about one-fourth its bulk of sand, and a little turfy loam, will grow Rhododendrons and Azaleas as well as peat; but they will also do very well in good sandy loam.

NEW PEA (*Essex*).—From what you say of your new Pea it must be a fine variety; but it is of no use attempting to send it out unless you have secured a reputation for it. Send half a pint of the seed at once to the Fruit and Vegetable Committee of the Royal Horticultural Society, addressed to Dr. Hogg, the Secretary, and it will be proved in the garden at Chiswick. If it should turn out all you say about it, the Committee will no doubt give it the character it merits.

ZICRYA DISEASED (*An Old Subscriber*).—It is covered with a species of scale (coccis). Treat it as we directed last week under the title of "Scale Insect on Cotoneaster," page 163.

NAMES OF VERBENA AND GERANIUMS (*Elencor*).—The varieties are far too numerous and too nearly alike to enable names to be given from small withered specimens.

PEACH SHOOTS GANGRENING (*Amygdalus*).—It is not being trained to galvanised iron wire that causes the gangrene, for we know many trees so trained that are not gangrened. We consider the roots have descended into a wet subsoil; or, at all events, that there is something wrong about them. Are the trees much overshadowed by Vines or other plants?

HERBACEOUS PLANTS (*Rusticus*).—See what is said to-day in "Doings of Last Week," and by Mr. Beaton.

PIT FOR FLOWER FORCING (*T. Danvers*).—An eastern aspect will do, though it is far from the best for the purpose.

VARIOUS (*A Subscriber, Brasted*).—You do not say what your Yucca is; but whatever it is, the flowering will be hastened, if kept in a pot, by giving it plenty of manure water in dry weather in summer, and keeping it dryish in winter. The steam of the dung-bed and want of air have injured the Achimenes. If you keep them there, spread 6 inches of ashes over the bed; set the plants on the bed, not in it, and leave a little air at the back of the frame constantly night and day. The fresh leaves will be saved; the discoloured ones will never come clear again. You may propagate your Gloxinia leaves two ways. The leaves you can spare take off, and plant them singly in sand round the sides of a small pot, as you would any other cutting, and plunge in a sweet hotbed, or merely set them on a shelf in a warm place where they will be shaded a little. Ere long a good tuber will form at the bottom of the stalk of the leaf. The other plan, though there are others, is to take the leaf, cut it into pieces, and insert the pieces like cuttings, and shade a little as above. The tubers will be smaller.

MELON PLANTS DECAYING AT THE COLLAR (*A. B.*).—Caused by too much moisture and a confined atmosphere. Your only chance is to scrape off the rotten part at the collar, and surround it with equal portions of lime and charcoal—a handful for each—and put a piece of cloth over the heap to prevent the water touching it, and give no water near the collar of the plant.

VINERY (*B. C. H.*).—If we were in your case, we would plant new Vines outside, raising the border if possible with fresh material for a yard in width at first, and keep the old Vines in the house, to get some fruit for a year or two, until the young ones came into bearing. We have no doubt that the Vines have got too deep and exhausted. If they had been at all strong, we would have raised and replanted them in October.

BROCCOLI (*T. C.*).—Your Broccoli (weighing 4 lbs. and 32 inches round) is very good indeed. Your remarks as to the waste of horse sewage are very true. We lose nothing of the kind we can save. We have reason to learn from Chinese and other orientals. We send thousands of miles for guano, and allow pretty well as good at home to be lost, or to be made into sources of pestilence and plague.

YOUNG PELARGONIUMS AFTER FLOWERING (*Oxford*).—These are more tender than large florists' Pelargoniums. They should not be dried so much, nor pruned so close. They are better without any bottom heat. Prune when pretty well hardened, and when they begin to break reshift into smaller pots, and if the roots are right prune them but little. We think you had let them become too dry, or put them into strong sun at once out of comparative shade.

STOPPING VINE SHOOTS (*An Amateur*).—If your Vines are spur-pruned, there was no harm in stopping all the shoots. If on the rod system, you must select the strongest that has broken afresh, and train that, and keep the others all stopped again.

FUCHSIAS WITH A SINGLE STEM (*Idem*).—To have strong rods of Fuchsias, you must commence with one shoot. Say, you have a nice bushy plant now; well, next Christmas, or before, cut that plant down to the ground, or below it, put it in a little heat, and save one shoot that comes out of many. If you strike a plant now, or later, that must be kept to one stem at first. If the plant throws out regularly, all well and good; but if not, the leader must be stopped, and a new leader chosen, so that the plant may be bushy to the pot, as well as straight in stem.

BEGONIAS (*M. F.*).—These new Begonias will do very well in a warm greenhouse in summer. They thrive in peat and loam, with a little sand. To keep the colour well, the plants should have a little shade in summer. In winter they like from 45° to 55°, and less water. They do not dislike a little bottom heat, especially in spring, and will have larger leaves in consequence; but they will do very well on the shelf of a stage.

NOURISHING COMPOST (*Sheffield*).—Nothing will answer better both as a deodoriser and an assistant fertiliser than the charcoal dust you can obtain.

GOOSEBERRY CATERPILARS (*A Constant Reader*).—In our Number for May 14th we mentioned dusting them with White Phosphore powder. Covering over the soil with tan about the roots prevents the larvæ descending into it.

VINE BUNCHES ULCEATED (*P.*).—Such appearances are generally the result of a too moist, close atmosphere, and want of regular root action, but is no doubt often the result of a want of ripening of the wood the previous year. When we have met with it, however, we have thought it to be caused by damp and cold. The fruit crops in general are unsatisfactory this season.

VEGETABLE MARROWS, &c. (*W. Dixon*).—Your Vegetable Marrows will do very well on long poles over an arch, over an arbour, or against a wall. Train to the height, or nearly so, and if on a pole then stop, and stop the side shoots at every other joint. If on an arbour, let them run with but little stopping. We have had them on a single pole, the main shoot carefully fastened to it, and all the others shortened about 18 inches long; but the fruit on them must be cut before they are over-heavy. A six-inch pot will do well for the plants you mention; but they will become drawn in a sitting-room, unless plenty of air is given. After the 1st of June they will do better on the window-ledge out of doors.

GERANIUM LEAVES (*Sarniense*).—The leaves of your seedlings tell that you have got into the strain of Baron Hugel and Bishopstow scarlets; but unless your superior climate assists you, you are so late in this field as to have little chance in the market against English breeders, who have been working in the same strain these ten years past.

PLANTING FLOWER-BEDS (*T. M.*).—Plant the six ray-beds in three match pairs; every two of them *opposite each other* plant with the same kind of plant, as two with yellow *Calceolarias*, two with some variegated *Geranium*, and two with *Tom Thumb*, or some dwarf scarlet *Geranium*; but as you gave no index to your ways of procuring the plants, the above is merely to show the right way to plant such beds standing apart in a group round a centre bed.

CUPRESSUS MACROCARPA (*J. S.*).—The discordant results of last winter's influence over the Conifers is very remarkable. On the chalk hills near Winchester, *Cupressus macrocarpa* is quite unharmed, whilst that of your friend, near Worcester, "has been nearly destroyed." No application to its roots, except water in very dry weather, will be of any use. In such dry weather syringing the stem and branches might be useful. If it vegetates let there be no pruning away of the dead parts until late in the summer.

NAMES OF PLANTS (*D.*).—*Pyrus aria*, the White Beam tree. (*A. B.*)—1, *Weigela amabilis*; 2, *Calycanthus floridus*; 3, *Viburnum lantana*; 4 and 5 appear to be, the former a *Cornus*, the latter a *Ribes*, probably *C. sanguineum* and *R. alpinum*; but there are no flowers. (*Hibiscus*).—The Fern is *Ceterach officinarum*. The small red flower, though much crushed, seems to be *Ailonea Warczewiczii*. The other leaf is not recognisable. (*S. Devon*).—1, *Potentilla tormentilla*; 2, *Lysimachia nemorum*.

FLOWER SHOWS FOR 1861.

JUNE 5th and 6th. ROYAL HORTICULTURAL SOCIETY. (Plants and Fruit.) *Garden Superintendent*, G. Eyles.
JUNE 5th. PORTSEA ISLAND. *Sec.*, H. Hollingsworth, Southsea.
JUNE 11th. ROYAL OXFORDSHIRE HORTICULTURAL SOCIETY. (Plants and Flowers.) *Sec.*, W. R. Hobbs.
JUNE 12th and 13th. YORK. *Sec.*, J. Wilson.

THINNING-OUT POULTRY.

WE left off at "exhibition fowls." Excellence, not to say perfection, will always be the exception in poultry as in everything else. The Lord Rivers, who was so well known for his love of greyhounds, and his almost uniform success at coursing meetings, was one day asked the secret of it. He said, "He bred well, trained well, and hung well." We believe this to be necessary wherever there is to be great competition.

We have passed the breeding stages, and we now have a yard full of promising chickens, rather an *embarras de richesses*—too many to exhibit, too many to keep, far too good to kill, and much too valuable to sell at market price. "What am I to do?" says the owner. "I wish the *Poultry Chronicle* would advise me." So it will, respected reader, and, it may be, fair correspondent. We are not intending to tell you that there is a place in London where they will make their weights in gold, nor that there is a person somewhere who will buy any number at any price; we are simply bent on advising you to ask the advice of a friend or neighbour about your birds. It is astonishing how easily they will overcome all your difficulties.

We will go with you among your Spanish chickens. Your arrangement is an admirable one, and having, as they have, a cottage run, we do not wonder at their looking so well. Now they are brought together, he good enough to show us your best. You cannot. Well, then, we will show you your worst. Kindly tell your lodge-keeper, or your labourer's wife, or whoever has charge of them, to catch up any chicken we point out. Look at that young Spanish cock, his comb is certainly not straight; now that scarcely perceptible twist will never be less, it may be larger, it will become more objectionable, but it will never disappear, and it will very likely bring the comb over with it. Catch him up, and those three pullets you say you consider the most promising. That you have been taught to look for long, thin, skinny faces, and you have it in them. So you have, but they are result of weakness and ill health; these have never grown as they should. If thin skinny faces are to be considered valuable in Spanish pullets—and they unquestionably are—they must be allied with first rate condition, and the pullet that looks "all skin and grief" must be as plump as a partridge when handled. Look at those pullets, younger by some weeks, their faces are not only skinny, but they are becoming white. Bad comb cock again, take him away. Very seedy pullets, take them away. This would be the burden of the song, and although you probably might in some instances have cause for remonstrance, yet you would be surprised with what facility a judge—without leaning, partiality, or favour—can divide and condemn chickens from a run, where the owner could see only perfection.

Having mentioned Spanish as the first, we will make a few more remarks on that breed. There was last season a marked increase in the number of amateurs of these beautiful birds, and there was a large sale for them at very good prices. They were also better in quality than they had been for some years. There has been an unusual demand for eggs, and, among the many chickens hatched, some will perplex their owners.

Those to whom poultry-keeping is a mere pastime, and with whom the expense is unimportant, can of course do as they like, and they may not care for our scribbles; but to those who wish to combine the fancy and the pocket, we say, Beware of pets, and beware of fancies. (Let neither your wife nor daughters go with you when you have hardened your heart, and determined to destroy some. There is a very kind-hearted, nice, blue-eyed girl who will not hear of the chickens she reared being killed; she is very mild, but she speaks with great firmness when she says she *will not* eat them if they are. Her dark sister says she hasn't patience with papa, and he may rear his early chickens himself next year. The wife and mother thinks it is unkind to tease the girls, and try their dispositions. The smaller ones don't care for the big chickens; but there are two or three little dears—one with a broken wing, and another with a crooked bill—that shall not be taken away; and when mischief says, Stop till they are gone to bed, they declare they will take the darlings up with them.)

Do not be led away with the notion that chickens will grow out of faults; they cannot do it. The curve in the comb of the cock, the slight hump or twist in the back of the pullet, the very trifling, almost imperceptible, bowing of one leg will only increase as the birds grow older. As we are still dealing with Spanish, let us say that as it is now admitted the cocks *must* have upright combs, there will be no excuse for keeping chickens that lack the quality. A defect in the comb is visible at ten weeks old in the cock chicken. It is impossible to speak with as much certainty about the pullets; but there is no difficulty in selecting those that are very long in head, body, legs, and face—the latter pale *all over*; eschewing such as are squat, round, and hen-like at an early age, such generally have small, round, white faces that do not drop; and others that have all below the eye perfectly white, while above it is an angry red, such seldom become quite white. Excellence in Spanish is in a great measure dependant on age, and, therefore, you may almost always make a fresh selection of your birds every month or six weeks. It is never safe to reject pullets too young, as many a valuable hen has been in danger when a pullet.

PROFITABLE POULTRY KEEPING.—No. 6.

(Continued from page 146.)

FOWLS AND THEIR BREEDS.—Their name is not exactly legion, but the pure-bred, and the numerous cross-bred, make up a goodly number. I shall confine my observations to those with which I had to do practically. My first lot were obtained as I could (*vide* No. 2, page 70.) I had—1, the Barndoor; 2, the Game; 3, the Dorking, speckled and white; 4, the Spanish; 5, the Everlasting Layer; 6, the Cochins; 7, the Poland; and many nondescripts.

This list must not be taken as placing the fowls in order of merit. After the first season I weeded rather extensively. My object being profit alone, I limited the stock to those breeds which had proved the best layers, the best sitters and nurses, and whose chicks were hardy and grew quickly.

When a late master of the Chapel Royal heard that a distinguished member of the musical profession had been knighted, he is said to have observed, "I suppose it must be on the score of his merit, not on the merit of his score."

Now I have placed the following breeds both on the score of their own individual merits, and on that of their progeny.

1. *The Speckled Dorking.*—This breed, taking it for all purposes, I place first. The hens are good layers, good sitters, and good nurses. Their chickens come quickly to profit, and are preferred by the dealers for size, plumpness, and good colour.

2. *The White Dorking.*—These are inferior in some points to the speckled, and superior in others. They lay scarcely so freely, are not so good sitters, are equal as nurses. Their chickens less hardy, but superior in colour.

3. *The Everlasting Layer* (Hamburgs).—This pretty and useful breed I hold in high favour. The hens lay from 200 to 250 (I have known 270) eggs in the year. I had one small hen, a silver-pencilled, which laid me 227 eggs in the twelve months (actually, ten months and two weeks, giving within a fraction five eggs a-week.) They were not large, but of excellent flavour; and the 227 eggs exceeded by over ten times the weight of the bird. This breed will not sit. I need scarcely observe that to keep up the breed, their eggs must be placed under other hens.—LEIGHTON.

(To be continued.)

MANAGEMENT OF PARROTS.

MANY persons have read with much interest the notes in your Journal in reply to queries about Parrots. Their owners mean well by them, but the poor birds suffer from the popular ignorance regarding them, and contradictory advice. The most general error is not giving them water, on the supposition that the birds do not find it in their own hot country, but get moisture from fruits. This point you have already settled by a note in your Journal, for which every thirsty Parrot should be greatly obliged. Will you now have the goodness to give some further information?

What should the Parrot have in his cage to grind down his bill on? The smooth wires of his cage seem quite insufficient, though he works much with them, and his perch-stick, which is also smooth.

Is it from any preventible cause that the Parrot at times eats his own excrement? May the Parrot be exposed to the full heat of the sun in his cage, when hung out for the air? When moulting the Parrot pulls out his feathers. Should anything be given to him to allay the irritation he appears to feel?—D. H.

[We insert this list of queries in the hope that those who have kept Parrots successfully will favour us by stating fully their mode of management. The thousands of Parrots in Great Britain are for the most part totally mismanaged, and we hope for the sake of those birds, and for their owners' sakes, we shall have many replies.—EDS.]

COMB-BAR HIVES.

CONTEMPLATING the adoption of bar-hives for my apiary, I want, in my own mind, to get rid of the solid crown-board as recommended by "A RENFREWSHIRE BEE-KEEPER;" but I do not like his substitute of grooves in the bars and slides. I am afraid they must be very difficult to work on account of the propolis which my bees use so lavishly wherever they find a crevice.

I have schemed the plan which I would now ask your judgment on; and which is, instead of one crown-board, a series of long narrow boards, or rather bars. The sectional drawing will, I think, make it clear. B Woodbury comb-bars. A Bars instead of a crown-board, or of the slides before alluded to. The plan shows a recess at c, in the under corner of each crown-bar, making a groove when two bars adjoin of a quarter of an inch square. I propose to have my comb-bars made with a ridge to work in the groove thus formed by the junction of two crown-bars; but I think it will be best if, instead of the ridge filling the groove, a space be left as o in the plan. My comb-bars will thus be kept in their places by the crown-bars without any need of screws. Of course, it will be necessary to make the centres of the two ridges of the comb-bars correspond, and to get the crown-bars exactly $1\frac{1}{2}$ inch wide. Or what is the proper width from centre to centre of the combs?

I propose resting the ends of the comb-bars on a ledge within the hive, cutting a piece off flat at the ends for this purpose, represented by the dotted line; but the crown-bars I would carry half an inch over the front and back. It would also be necessary so to adjust them as to rest flush upon the comb-bars. For supering, holes may be made in the crown-bars, or the whole bar may be removed, and two pieces, leaving the middle open, substituted. When resting in working order they would need no fastening more than the propolis of the bees themselves; and if fastening should be at any time needful, it may be accomplished by screwing one or two bars across, the sides of the boxes being made higher than the back and front, and level with the crown-bars when in their place.

Now, I shall feel obliged if you will point out any flaws in my plan. Will the crown-bars warp? How thick must they be? Is it certain whether bees do better in wood boxes or straw hives? Is a "RENFREWSHIRE BEE-KEEPER'S" assertion that, for concentrating the heat in the spring, there is no comparison between an octagon or circular hive and a square hive, the advantage being with the former—is this assertion true equally for southern and northern counties? or is there but little or no perceptible difference in the prosperity of square and round colonies in the south?—A. B. C.

[Your plan is ingenious, but we fear rather too complex for general adoption. The only inconvenience we have ever found in the use of the ordinary crown-board, is completely removed by allowing sufficient space for the bees to pass above the bars. We now allow about $1\frac{1}{2}$ inch from centre to centre of each bar. The Woodbury-bars are intended to rest in the same notches as common ones, so that it is only necessary to remove half-an-inch

of the central rib at each end. The proposed crown-bars will not warp, and should be the same thickness as the sides of the box. As far as our observation extends, bees appear to do equally well in wooden as in straw hives. The assumed concentration of heat in octagonal boxes is doubted by many. There is certainly no perceptible difference in general between the prosperity of bees in hives of either shape.]

SEQUEL TO THE ADVENTURES OF A LIGURIAN QUEEN.

IT is with much regret that I lay before the readers of THE JOURNAL OF HORTICULTURE the following letter, which appears to indicate a disastrous termination to the "Adventures of a Ligurian Queen." I say appears to indicate; for it is by no means certain that the formation, or even the completion, of queen cells, is proof positive of the sovereign's demise.—A DEVONSHIRE BEE-KEEPER.

"My dear Sir,—I hasten to inform you (May 23rd) which I do with much regret, of the failure of my hopes in regard to the first Italian queen, whose "adventures" have been recorded in the pages of THE JOURNAL OF HORTICULTURE. The sequel to those adventures is so far interesting (albeit in other respects most unfortunate) as indicating that no positive rules can be laid down as to how bees will act under given circumstances. Either they must have killed the queen outright, or else have stifled her to death, even after the discovery of the loss of their own queen; for they certainly did discover their loss on the 12th, as witness the "hum," of which I spoke in my former letter. Ever since that day they have been perfectly tranquil, as if all things were in a right state in their hive.

"All doubt as to the fate of the poor Italian queen was removed this morning, when curiosity, and the desire to transfer the bees to a bar-box, led me to drive the whole population, when I discovered four royal cells in close proximity to each other celled in. The piece of comb in which are these cells has been cut out, and placed in a glass over the box which contains the driven bees. The moment the hole communicating with the box was opened, the bees rushed up in frantic joy, and instantly took possession of the glass.

"I have also just examined the old stock from which I drove the swarm last Friday, in preparation for the second Italian queen, which arrived dead,* and saw two royal artificial cells celled in. The bees in this hive being rather few in numbers, I have set the old box (driven this morning) over them. It contained several hundreds, perhaps a thousand, drone and worker cells, containing unhatched bees, besides a few fully-developed bees that would not join the swarm. The box itself weighed about 20 lbs., and contained a good deal of honey.

"Thus most unfortunately ends my first experiment with the Ligurians. I must hope for better luck next time. I only wish I had your queens at the head of my very strong stocks. So far I have suffered nothing by these experiments. The two swarms have taken the place of the stocks which perished in the winter; and the old stocks are full of honey and young bees, with a prospect of healthy young queens.—B. & W."

ON THE SUBSTITUTION OF A STRANGER FOR A NATIVE QUEEN.

THE too-probable failure of so good an apiarian as "B. & W.," in his attempt to substitute a Ligurian for a common queen, is much to be regretted; and a few words on the causes which appear to have led to that failure, as well as the best means of insuring future success, may not be without interest to apiarians.

I cannot learn from the letters of my esteemed correspondent whether he at once placed the Italian queen in communication with her future subjects, from which she should have been separated only by a divider of perforated zinc for the first twenty-four hours. I shall assume, therefore, that this very necessary precaution was not omitted, and can come to no other conclusion than that the unfortunate impatience which led to

the Ligurians being "stirred up with a bit of tarred string," was the sole cause of failure.

Most bee-keepers are aware that bees manifest the greatest anger, shown by an instant protrusion of their stings, on being interfered with in this manner; and I can conceive no more probable cause of a fatal quarrel than such an operation effected by the use of so obnoxious an instrument as tarred string.

Huber's experiments would lead any one to suppose that, after bees had been without a queen for twenty-four hours, they would at once accept any stranger sovereign that might be offered to them. Such, however, is not the case, and it would be extremely hazardous to present a strange queen for their acceptance at the expiration of twenty-four hours, when most probably a number of queen cells would be in course of construction.

There are two periods when bees will generally welcome a strange queen. One is after their own efforts to raise a queen have failed or have been frustrated, and the other is when the stranger is presented to their notice during the confusion incident upon the first discovery of the loss of their own sovereign. To take advantage of the first-named period, it is necessary to remove the native queen about ten days before presenting the stranger. During this time the hive must be twice examined and all queen cells extirpated. In practice, however, I have found it impossible to make sure that no queen cell is overlooked; so that it is more than likely, after all this trouble has been taken, that the new pretender to the throne may find herself face to face on her first introduction with a virgin princess, whose superior activity would, most probably, at once determine the contest in her own favour.

Dismissing, therefore, this mode of proceeding as being well nigh impracticable, there remains only for us to take advantage of the first moment of confusion produced by the discovery of their queen's loss, and this is what I have endeavoured to do in the instructions for uniting Ligurian queens to stocks or swarms, which were republished last week. I do not say that a failure is impossible, even when these instructions are faithfully carried out; but this I can say, that no such failure has, as yet, come to the knowledge of—A DEVONSHIRE BEE-KEEPER.

HOW I BECAME AN OXFORDSHIRE BEE-KEEPER.

(Continued from page 74.)

MY bee-boards are fashioned like the block-boards, out of well-seasoned guarled ash, about 1 inch thick, being 19 inches in diameter one way, and 2 feet—the alighting-lip side—another; half-an-inch is bevelled off around their upper edges, and the alighting-lips are left 5 inches broad for a base, and tapering off to three-inch rounded extremities. The inch-thick boards will allow of planing, in case of future warpings, as they must always offer an even surface for the hives, and also lay close and level upon the block-boards; for, in the event of cavities there, so sure will woodlice, earwigs, &c., congregate. I have some bee-boards formed out of mahogany, they can be depended upon for neither splitting nor warping; and for those who can afford to launch into the expense, doubtless they would prove less costly in the long run. A board I have had in use from the beginning, is made out of three-quarter-inch deals, with two two-inch-broad oak strips let in flush, and transverse across the bottom; it has never warped or given way in the least, and would last ten years longer. Stone or any similar cold substance must be avoided for this purpose. And now I am on the boards, I may as well proclaim my manner of cleaning them for the bees, in the spring time of the year.

In order to prevent counter currents across them during the winter, I never, if I can possibly help it, lift those hives from the boards after September that I intend to keep as stock, in order that the bees may thoroughly glue them to the boards with their propolis before the cold weather arrives, for then they cannot work this substance; and positively all mortar daubings must be execrated. I do not perform the board-cleansing before the middle of March, or even so early, unless the weather is mild and warm; and when these conditions favour, in the middle of a sunshiny day, when the greatest number of the bees are away at work, I proceed as follows:—With a clean spare board, a plant knife, a hard brush, a goose's wing, and a stout wicker-worked bushel measure, 14 inches in diameter at top, and tapering outwards towards its bottom—this I place handy on the walk,

* This is the first of my queens which has died whilst travelling. Judging from the fact that all her attendants survived, and that her own sting was protruded, I have little doubt that she met her death from a thrust (whether accidental or wilful it is of course impossible to determine) from one of her subjects' weapons.—A DEVONSHIRE BEE-KEEPER.

† This "old box" has thus given me two good swarms within the fortnight, which now stand side by side on the top shelf of my apiary.

and then press the inward shank and knee of the right leg against the edge of the board, and the back of the hive; lean over and grip the bee-board with the left, and the top front edge of the hive with one's right hand, and with a strong and a loup pull, pull the hive over at once, and place it upside down upon the measure, examine its internal condition, and take quick cognizance of what is perceived to be wrong, in the shape of combs becoming too thickened by age, weakness of inhabitants, mould, moths, or any other adversity for future guidance; then slip over the clean board, meantime whisking out of the way with the wing the bees, from off the edge of the hive to prevent their being crushed; put aside the dirty board from the stand, examine the pedestal at the junction of the ground, and with a few good tugs from right to left, make sure of its being sufficiently sound to bear the bee-hive another year. That ascertained, shift the hive sufficiently on to the edge of the measure, so as to be able to insert the right palm and arm beneath it, whilst with the left palm upon the board, press tightly, and with main strength turn over the hive to its proper position; set it on its stand, and place the pan over it.

From what I have written about the latter protector and the controversy it has caused, I trust my readers will not consider my "pan" to represent the meagre dumpty affair too often seen placed on the tops of hives. Mine are made $11\frac{1}{2}$ inches wide across the bottom, with sloping sides, $7\frac{1}{2}$ inches deep, and measuring 2 feet for their top inside diameter; so that when reversed on the hives, which are 16 inches broad, there remains a good conservatory air-medium between the pans and the tops of hives, which I consider most important, and their slope extends so far over that during the winter time, little more than one-half the hive can be seen. I place the pans, moreover, rather leaning, and their being provided with rims, the drip water is made to cast itself off at the side indents, where their lips are formed; and unless it is very driving, no rain can reach the hives, and no wet can lodge for long on the edges of the bee-boards, or their alighting-lips, on account of the slight incline which is made permanent at the sawing off the tops of the pedestals in the first instance. The insides are glazed at their making, and their outsides I have painted the same colour as the under sides of the stands, and these are the only parts of my bee appendages I allow to undergo that operation. The cock-a-hoop balance of the pans, surmounted with the old bits of sculpture—as wind guarantees—have a nobby appearance I assure you. Proceed now and scrape off the residuum from the removed bee-board with the knife, and polish it off with the hard brush, when it will serve as the clean one for the next hive, and so on; and, my word for it, it will do your very heart good to observe the rejoicings of the bees for this, your provident care—it is a regular romping fowl's game of prisoner's-base—they appear so happy they do not know what to do. This year my anxiety for inspection on account of the late severe winter, and this, my contemplated writing, induced me to take advantage of the 9th inst.—the first warm day of the month—to perform the cleansing operation; and the remarkably dry and healthy exteriors and interiors my hives presented were marvellous, I could have blown away the waste lamina from the bee-boards with a pair of hells. Consecutively, as I turned up the hives, I found the bees congregated centrally, intent upon their household arrangements, and their combs were becoming quite heavy with brood.

On the 20th inst. the weather was very cold and stormy, and as I have 3 lbs. to 4 lbs. of honey left, I shall make it into food, and give it to the bees; not that they absolutely want food, but it will assist our economy, and be of advantage to their brood, for where there is a large family coming on nothing must be allowed to be wasted. I explained at page 186, Vol. XXV., of THE COTTAGE GARDENER, the method of feeding, and the size the feeders are made so as to fit the winter entrances, for which I have also another name—namely, ash-pit doors; and now I mention them, it opens an opportunity for me to explain them away, and to send you a drawing.

I place a portion of cotton wadding at their backs previously to tacking them on to the hives, to prevent the exit of the bees between them and the irregularities of the latter, for the insects will insinuate themselves through a surprisingly small hole. They are made of zinc, 4 inches by 2 inches, with a perforated slide to slip over the bees' entrance early on sunshiny or thawing mornings, when snow is lying upon the ground, for in default of some such contrivance the bright light or warmth tempts on the bees, and the snow lures them to destruction. I take especial care to raise the slides again in the afternoon, as the

inmates have a great repugnance against being placed in the position of Sterne's starling; and although not one should be seen at the closing of the slides, it is amusing to watch their probosces soon after, working through the perforated holes, as much as to say "We can't get out—we want more air!"

WINTER ENTRANCE TO BEE-HIVE.

1. Zinc plate, 4 inches by 2 inches.
2. Bee entrance, $1\frac{1}{2}$ inch by three-eighths of an inch.
3. Slide, with five perforated holes opposing entrance.
4. Holes to admit tacks to secure plate to hive.
5. French-cloth-looking tacks for the above purpose seven-eighths of an inch long.

Now, chiefly as well as for cottagers, I have it before my mind's eye and knowledge, that many gardeners—good sort of people—are requested to undertake the management of a few hives, if not to produce honey for the nursery—and what is more wholesome and palatable for children, or the parlour breakfast table? at least, I beg pardon—for the housekeeper's stores; and whatever I may know, or think that I know, about the principles of air in motion, it may tend, perhaps, to a quicker comprehension of what I am about to say, if we go and sit down on the steps in the stoke-shed, quietly discuss the matter, and take the furnace and ash-pit door for our text. Now, as to whether it is the Killogie, Polmaise, or Kiddean system that my bee-keeping hangs itself upon, no matter; it is very much like one of the three, which is not Polmaise, nor yet Killogie. At any rate, I did not finally adopt the plan without many a good think, or enter the list of apian advisers without well considering the state of my armour either; for most assuredly we are quick to defend our workings, and our ways are endless, though, I believe at heart we bear no ill will to each other—at least, I know I do not. It is understood that bees possess the power to generate heat, more or less, under favourable circumstances as they may need to require it (their respiratory action is nicely touched upon by "A RENFREWSHIRE BEE-KEEPER" at page 202, Vol. XXV., of THE COTTAGE GARDENER), which that furnace has not, neither could it much, however so well supplied with fuel; if we stuffed up the chimney-flue, albeit the ash-pit door is left open; and this is much upon the principle that bees are too commonly allowed to struggle and try to exist. You and I could not sit here so comfortably outside the brickwork, much less inside, under those conditions. Then fancy a hive swaddled up, every flue choked, the interior reeking with steam, damp, cramped, its inmates faintly breathing, and doubtless they would cry out if they could—"We do not *live* here, we only *linger*; we are so cold! Do pray give us a circulation of fresh air: we will soon warm it, and take care of ourselves! Oh! that we had been allowed to choose a hollow tree, or a commodious hole under the roof of a house!"

On one of those bitter cold days last Christmas, my friend, whilst holding converse about our bees, expressed himself somewhat dubious and inquiringly, I thought, concerning the lives of his stocks; so I took him to my apiary, bid him kneel down in the snow, and place his ear close to each hive and listen. The combined surprise on his countenance I likened to those ever-to-be-admired spirits of the waters around the fountain in the tropics at the Crystal Palace; or, if you do not happen to have been fascinated by those nymphs, place a sea-shell to the ear of a child for the first time, watch the mystery of its countenance, and you will have little difficulty in arriving at my meaning. My friend intimated that no time would be lost ere each hive of his underwent the listening test; and if, I answered, you hear not the mellowed voice as of a distant waterfall, you may

depend upon it there is little life there. But you will observe that my hives are 16 inches in diameter, 11 inches deep, straight-sided, of common thickness—about an inch—with well-twisted wattles, firmly bound together with the withs, and of straw throughout, the summer or natural entrances being about 2 inches by three-quarters of an inch, quite flat on the top, having central holes about 3 inches in diameter, over which are placed thinish rounds of plaited straw, slightly secured with wall nails, though sufficiently so as to prevent the egress of the bees. This I call my air-flue; but the bees would stop up a pipe of "X." (page 358, Vol. XXV., of *THE COTTAGE GARDENER*), directly, if it was allowed to come down into the hive, and we should then have juice in plenty, and the wrong sort too. As to the turf over, doubtless it is as good a non-conductor of heat and cold as peat. My hives are after the model of Mr. Payne's, but his are 14 inches by 9 inches only, outside measure: therefore you will perceive mine to be a good-sized oven, and the bars—viz. the combs, reach from the top nearly to the bottom: I say *nearly*, for that is an important particular.

If you adopt the hives that I recommend, you must also adopt for each two pieces of hard-wood sticks, to run completely and centrally through at right angles, otherwise the bees from their own natural instinct, will attach some of the lower parts of the comb to the bee-board for support; so that not only would spring feeding become impeded, but in the event of summer examinations and spring cleanings, when the hive is lifted, smash must go the combs somewhere, and more or less of them remain attached to the bee-board, which would cause a sad difficulty, and future cost of time and store for the bees to repair. I have never found this to happen since the introduction of the sticks. My first large hive, to which I have never applied them, was sadly subject to those attachments in its youth. When I lived near the banks of the Tyne, I practised fly-fishing, and made my own rods; so happening to have it by me, I use hickory and lance-wood for these cross purposes, worked into lengths about three-eighths of an inch in diameter, taking the precaution at their insertion to leave about an inch of each protruding outside the hive, to enable me to twist and pull them out of the way with a pair of pincers previous to cutting out the combs. I find it is customary for bees to commence eating their stores at the extremities, and to retire from the combs inwards. Some years ago I first noticed this peculiarity in a Nutt's pavilion-hive, which was intrusted to my keeping by a lady for several months. I allowed the bees to work in one of its collateral-boxes, and after the honey-gathering season, they conducted themselves as mentioned above; they had nearly consumed the honey in the collateral-box, and retired into the central compartment for winter quarters, when I was requested to send the apparatus, by rail, into Hertfordshire, where it arrived safely with its sweets and living cargo. Now when straw hives are made sufficiently roomy, and the bees are giving out central heat, what a capital medium we provide for the warmed air to circulate between the space there—the comparatively isolated-oven sides of the hive, and the emptied combs—why, 1-inch space there is worth 3 inches in thickness of any outside covering whatever. I ally two swarms, two casts, and two colts—if I can get the latter for nothing—together, to populate each hive (of which more anon); so you see my furnace is a large one to produce heat, more or less according to necessity; and when, from the natural combustion to the bees, the air becomes more sensibly warmed, it circulates more freely, and ascends through the aperture by the straw plating above, provided a fresh supply is being introduced at the ash-pit door below; for it would be about as easy, I suppose, to keep down rarefied air in motion as to stay ignited gunpowder. In short, the fire in the centre—the bees—is fed by a portion of the outer air from the entrance as it goes up splitten between the combs, whilst side streams also go up in the surrounding side chambers, thence to rush out at the aperture into the conservatory to struggle round about and prevent stagnation outside the hive, and then away from beneath the great pan into the open air again, and there you have a description, and the "only secret from first to last" that I know, anent the preservative qualities of my hives; unless indeed it be the significant fact, that the bees remain to me alive and well through this and the last very severe winters, thus more than successfully competing with other common systems.

On the 23rd of March I was obliged to take away the winter entrances, by reason that they did not offer sufficient room for the exit and entry of the bees; they were so busy about the

apricot, crocus, and *Arabis mollis* blossoms. The latter is the best honey-producing plant that I know of from the middle of March to nearly May. It is very hardy, and can be propagated in any out-of-the-way corner for autumn transplanting into beds and borders, to form a nice green surface during the winter. It is most profuse with its clear white bloom, very appropriate for the ribbon fashion, and very interesting for those who like to study the varieties, and to hear the "murmurings of innumerable bees."—UPWARDS AND ONWARDS.
(To be continued.)

MANAGEMENT OF PIGS.

THE fame of the little village of Brandeston, in Suffolk, rests, we believe, solely and recently upon the very superior excellence of the Pigs bred there by a very intelligent farmer of the name of Stearn. That his fame is well-merited appears from many facts, but from none more decidedly than from his being requested by his brother agriculturists to read them a lecture upon the management of swine. This he did, as follows, at a meeting of the Framlingham Farmer's Club. It must not be supposed that Mr. Stearn's Pigs came by a string tied to their leg, or covered over with a net in a dealer's cart. The pigs would scorn such treatment. A short time before the hour for the discussion there was a great commotion in the town. A procession of cars tastefully trimmed with flags, evergreens, and flowers passed through, the horses mounted by postillions in scarlet jackets and blue caps with scarlet tassels. The procession was received with cheers and much popular ovation. The occupants of these triumphant carriages were Mr. Stearn's Pigs, come to take their part in the discussion:—

I have had experience in management of Pigs a good many years, as many in this room are aware. I exhibited a sow and Pigs at the Framlingham Show as long back as 1847, and gained the prize; they were then considered superior to anything that had been seen in this neighbourhood, and many said I should never produce another lot so good. But we keep progressing, for at the Framlingham Show last year, I exceeded the former very much in weight at the same age. The same remark was then made again, but the two lots I showed at Birmingham and Smithfield were heavier still at the age; and now I suppose I may make up my mind I have got to my furthest on that point, as I have raised between 14 stone or 15 stone, 14 lbs. to the stone, at the age of between five and six months, dead weight; and between 8 stone and 9 stone, 14 lbs. to the stone, live weight, at between twelve and thirteen weeks old; and I think I have now, in the breeding of that animal, arrived as nearly at perfection as I could reasonably hope. But it is difficult to know where to stop, for even improvement has a limit, and crossing when carried beyond a certain point will generally end in deterioration. I think, however, to cross occasionally as far distant as possible is beneficial. To give an extended outline or description of the original species, or of the various breeds and innumerable crosses and varieties of Pigs, would occupy too much time: therefore I shall just describe our own Suffolk Pig. I find that the profit or loss of the Pig rests on the quality of the stock, and it must be kept in mind for what purpose the animal is intended, whether for bacon or pork. If for bacon flitches, you must choose a large kind, such as Berkshire; but if for pork, the small kind is most desirable, such as the Suffolk or Leicester, which are very similar animals; and every judicious breeder will have to take into consideration many circumstances in choosing a breed of Pigs. The intent and purpose of breeding is profit. To insure the greatest amount of profit, it would be well to consider the position in life of the population resident near one's own locality; his proximity to a good market, and a kind and quality of meat necessary for its supply. There is a Pig called the Improved Black Suffolk, which many prefer to white, thinking they are more hardy; but I have fairly tested the thing of late (which I suppose most present have been eye-witness to), and proved that the white will exceed the black as far as early maturity is concerned, and of course early maturity is where the profit is gained; and I find the better the quality of breed, the more lucrative it becomes, much less food being required.

Now for our White Suffolk breed. In choosing the sow and boar the chief points are—a smallish head, with short snout, wide chaps, the ears rather small and thin, ends sharp, pendulous and pointing a little forward, broad and deep chest, round ribs,

long in the body and short in the leg, the haunch or thigh dropped almost to the hock, back broad, straight or slightly curved, shoulders and hams thick, and the neck to rise well behind the ears, small bones in proportion to the flesh, the hair to be long, thin, and silky, tail small and curled. Strict attention to these points in selection cannot fail of perpetuating good stock. Here I must add my surprise how careless breeders are in selecting the boar for their sows. If there happens to be a good animal within a short distance, for the going to which half-a-crown is charged, they will often send double the distance to a thoroughly bad-bred ugly brute for the sake of the gain of a shilling. Whilst this apparently paltry gain is so much looked after, improvement is out of the question. As to the time for breeding, the sow should be from ten to twelve months old, and the boar from eight to twelve months. I, however, find that very few people will keep them so long, but breed them much earlier, which very often prevents their growing to the proper size, or acquiring sufficient strength for breeding. I think good-sized sows are best for breeding, and more likely to have a good number of Pigs. Great care should be taken not to have one with less than twelve paps, for it is observed each Pig selects a teat for itself. I consider twelve good Pigs to be sufficient for any sow to bring up. The sow I exhibited at Framlingham and Canterbury last summer, has brought up fifty-one Pigs in four litters, without losing one. As far as my experience goes, the time of gestation averages about a hundred and thirteen days, or sixteen weeks and one day. Two good litters in a year are all we ought to expect. When a sow is in pig, she ought to have liberty and plenty of exercise. The boars kept for stock should be confined in a shed with a roomy yard; if allowed to roam about, you are likely to get wrong in your breed.

In managing the sow at the time of farrowing, my practice is as follows:—To have a man with her to attend her; for it is absurd to have all the trouble and expense of keeping a sow, then, at the most particular time to leave her alone to take her chance. In my idea, there is not sufficient attention paid to the construction of piggeries; I have seldom seen one which I did not consider too small, except perhaps just for fat Pigs, which, of course, do not so much signify, for the less a Pig put up for fattening moves the better. But the farrowing pen ought to be large, to allow the sow plenty of room, and likewise to admit of rails being placed round the sides, so fixed as to prevent the sow lying on the young ones. These rails should be made to shift according to the sow, I think in height from 8 inches to 12 inches, and extend out from the wall about 9 inches, leaving the supports carried up sloping from the inside, instead of straight up from the floor; then when the sow lies down, there will be no likelihood of her squeezing the Pigs, as there is plenty of space left for them to pass between her and the wall, for nine times out of ten that is where the mischief is done, as sows invariably like to lean against something when they lie down. I have recently had a hundred Pigs, without losing one from being crushed. Each place ought to be, at least, from 8 feet to 10 feet square, and the best floor, I consider, is asphalt—no damp or scent can rise from that. I tried boards, bricks, and almost everything in the way of floors. Most persons would say boards are best, but I think I can convince you to the contrary. If you will consider, for only one minute, they cannot be healthy; for if the boards are placed close, of course the moisture will stand, and the boards become saturated: and if a space is left, the refuse litter will go between, so it will become one mass of putrid matter underneath, quite level with the floor, whatever the depth may be; for what passes through will absorb the urine, and is likely to bring on many diseases. But I think, it is well, in the cold weather, to lay down a false lattice floor on the asphalt, so it can be taken up once a-week, and everything swept from under. For two or three weeks, when the Pigs are very young, I have the beds attended to and fresh litter every morning, for I find the cleaner the place is kept the better the Pigs thrive. The floor being washed once or twice a-week, everything runs off, and the asphalt dries in a very short time. There is another great advantage: it does not take more than two-thirds the straw it requires for any other floor; for the moisture appears to run under the litter without wetting it so much, as it is laid a little on the slope; what is taken from the inside serves as litter for the pounds outside, which ought to be paved in some way to prevent the Pigs from rooting. By following this plan, the manure is made very regular and good. A tank should be made just outside, to receive the drainage from the pounds; the building to be troughed to take off the rain water, to prevent the

manure being washed. The pens ought to be so constructed as to be closed up in cold weather, and well ventilated in warm.

At the time of farrowing I allow a very small quantity of litter cut short, and have a hamper placed in the pen with a little straw at the bottom, and also an old blauket. I put a slip or partition, about 2½ feet high, across the pen to prevent the sow getting to the hamper; as the Pigs come forth, put them into it, and cover them up, until the sow had done farrowing, after which I put them to her and let them suck. When done, put them back in a hamper, give the sow a little warm milk and bran; and whilst she is eating this, have the bed attended to, by removing all the wet straw, &c. Add a little fresh litter cut short; then when the sow lies down, let the Pigs go to her again. By pursuing this plan there is very little danger of losing them, for I believe one-third are lost for the want of proper attention. I always give the man sixpence per head for all the Pigs he can bring up to a fortnight old. I find this much the cheapest plan, for then there is no fear but he will see to them properly, and attend to them in the first instance, as well in the night as the day.

How often do we hear people complain of the sow eating her own young: therefore steps ought to be taken to prevent her doing so; for when once a sow does that, she is very little use for breeding purposes. If you allow me, I will explain what I have found to be the cause. In some litters the side teeth are much longer and sharper than in others; when this is the case, and the Pigs begin to suck, they bite and scratch the paps, and punish and irritate the sow to such a degree that it brings on inflammation, and the sow becomes mad with rage, she throws some one way and some another. At last she bites them, and if she once draws blood, she will begin to eat them. Now, the way to prevent this:—When the Pigs are a few hours old, I have them taken away in a hamper, so the sow cannot hear them, and nip those teeth out with a pair of pincers. I should have lost a lot of thirteen some time since if I had not pursued this plan, for the sow was as near mad as possible, she threw the Pigs all over the place, and I had great difficulty in taking them away, for she would not allow any one to approach her. As soon as I had drawn the teeth, and put the Pigs back, she was as kind to them as possible, and perfectly docile.

I think about eight weeks old is a good time for weaning the Pigs, and I like to have them operated upon a short time previous. As far as the feeding of my Pigs is concerned, it appears the public know more about it than I do myself. Some say I give them sugared milk; some, when they think my back is turned, put their hand into the troughs and taste the food, and say they are sure it is phisic; others have stolen some of the food to have it analysed. Now I will try and explain how I feed. I begin to feed the young Pigs at five or six days old, with warm milk, mixed with a very little fine sharps, and a small quantity of white maize, out of troughs like some I will show you presently. For the first few weeks after being weaned, I have the boy feed them very often, but give them a very little food at a time, so they will clear the troughs out. In the winter I feed all with warm food, but not in the summer. I give them a great variety of meal, such as wheat, maize, barley, oats, and whatever is most convenient to mix together. I just wet it with cold water, and then scald it with boiling water, and sprinkle it with salt; between meals, I give them whole maize, and mangold wurtzel or swedes cut small; and once or twice a-day a little coal, but not too much, as it will be likely to do them harm. I allow them plenty of clean water, and there is one point I am very particular about, not to give them any more food than they will clear up at a time.

When Pigs are put up for fattening, it will be found very beneficial to wash them, at least once a-week; this is quickly done by experienced hands, and will amply repay any one for the trouble. I also like to have them very often brushed. If you will only try the experiment between this and the common mode of treatment, you will be surprised at the difference. I have no doubt that many will say, "What a trouble!" But how can we succeed in anything without trouble? I am certain the cottagers would find their Pigs fatten a good deal faster if they would wash and brush them, and feed them with warm food, instead of giving it to them all like ice. This would be a very easy thing, for most can keep a kettle by the side of the fire all day; they would find themselves well paid for the little extra trouble it might be.

Store Pigs ought to have their liberty as far as convenient, such as to range in large yards in winter, and the run of a piece of pasture in the summer. They should also be fed two or three

times a-day. Good-bred and well-fed store Pigs will always consume the refuse from the farm and dairy, when a bad-bred one will refuse. I have never known mine refuse anything in the way of pig food yet that was offered them, not even the prize animals. In my opinion the generality of pig-troughs are very badly constructed, so as to waste a great deal of the food, and soil it, by allowing the Pigs to get their fore feet in. I have tried a great many different sorts, and find those that I have brought here to-night to be the best kind I have seen, to prevent both spoiling and soiling; and they are called the light iron Norfolk troughs. They cannot be too flat according to the size of the Pigs to prevent their getting deformed. Their shape is very often injured through not using a suitable trough. I have a great many different sizes, and use them to suit the animal. And now, gentlemen, if any of you would like to see my places and animals at any time, I shall be happy to show them to you; but I can't say I wish to see you all at one time. I have had as many as sixty and seventy in a day, and that is rather too much of a good thing. (Prolonged applause.)

Some extraordinary specimens of Mr. Stearn's success in the breeding and rearing of Pigs were then brought into the room, engaged the attention of the meeting for more than half an hour. The first animal produced was a breeding sow belonging to a neighbour of Mr. Stearn, which was produced as a contrast to his own. When this animal was placed side by side with one of Mr. Stearn's, the contrast produced a great deal of merriment; but we were informed by those competent to speak on the subject, that the unhappy Pig which was produced as a foil on this occasion was not an unfair sample of the run of young breeding sows. Its age was about nine months, as was also that of one of Mr. Stearn's placed beside it, the former weighed 4 stone, the latter about 16 stone or 17 stone. Mr. Stearn also showed three white Suffolk sows in pig, of remarkable weight and proportions. The last specimen shown was a young boar from the Framlingham and Canterbury prize sow. Mr. Stearn also showed one of the light Norfolk troughs he uses, along the top of which he had added a bar to prevent the Pigs from attempting to leap over, in doing which he said they would often break their legs. He also produced a specimen of the wedge-shaped lattice he uses, which has the effect of fending the sow from the wall when she lies down, and so leaves room for the young to escape uncrushed. These contrivances were simple and excellent, and served, no less than the wonderful specimens of the Pig tribe which he exhibited, to convey an idea of his great care, perseverance, and skill in the work in which he takes so much delight.

VARIETIES.

VEGETABLE TALLOW.—The Agricultural Bureau of the Patent Office has received specimens of vegetable tallow known to botanists as *Myristica sebifera*. It comes from a nut about the size of a nutmeg, full of meat, which, being melted, becomes a yellowish tallow, excellent for candles. The plant is a native of Central and South America, and naturally attains a height of 10 feet or 12 feet; it carries herbaceous flowers from July to September, and makes so profuse a secretion of oily matter, that this may be readily obtained from it in the form of fat by immersing it in boiling water. H. L. Clarke, Esq., U. S. Minister at Guatemala, writes that he has no doubt that this article might be collected and exported at considerable profit. It grows in immense quantities in the southern departments, and in Verapaz. It is susceptible of such high purification as to resemble the finest sperm, is solid, and quite as transparent. A sample of this production, in the nut and in the tallow, is now among the numerous collections at the Patent Office. The cultivation of it from the seed will be tried at the Horticultural Garden.—(*Scientific American*.)

PRODUCTIONS OF EASTERN AFRICA.—The necessities of life are cheap in Enarea; for a piece of salt, worth not more than a groat, you may buy from 60 lbs. to 70 lbs. of coffee berries; and at the same price three great pitchers of honey, or several sacks of wheat, are procurable. Pieces of salt are however, rare. Like the Abyssinians, the Enareans drink beer and mead. The coffee tree grows wild in the woods to the height of from 12 feet to 14 feet, and its wood is used for fuel in the cold parts of the country; and in Enarea there is said to be more coffee than in Kaffa. What a pity that there should be so much difficulty in communicating with countries like these, from which so valuable an article of commerce could be procured! What

results would arise if the Gojob were found to be navigable, or if the river Sobat should conduct to these coffee countries! And how much more important still would this be for the extension of Christianity in Inner Africa! The traders from Gondar carry to Enarea the following articles of commerce:—pieces of salt, glass beads of various colours and sizes, coloured stuffs, especially blue calico; copper, knives, scissors, nails, weapons, cooking-ware, black pepper, &c.; and receive in exchange coffee, civet, slaves, horses, and the skins of lions and leopards, especially of the black leopard (*Gessela*). Civet is dear, even in Enarea, as it is considered a good medicine for the headache and other maladies, and is procured from the civet cat, which is as large as a young dog. This cat lives in the woods, where it is caught in traps, and is then kept in cages in front of which a fire is burnt daily to make it perspire. It has in its hinder parts a little sack or bladder in which the precious material collects, and this is emptied with a spoon from time to time and put into a horn, which, with its valuable contents is sold to the traders. The Galla horses are very small, but beautiful in colour, and extremely swift, though horse-shoes are unknown. The Gallas in the neighbourhood of Abessinia are tillers of the soil as well as breeders of cattle, while their brethren under the equator are merely pastoral, and lead a nomadic life. Those of the equator, moreover, have no horses, and are altogether far behind the others, presenting the genuine type of the original Gallas, especially in their religious notions. Where the Gallas follow agriculture, the men plough, sow, and reap, while the women look after the oxen, cows, horses, sheep, and goats, and take care of the house and its concerns. Rye, wheat, barley, and Indian corn, grow in such great abundance in the Galla countries, that for a dollar you may buy almost more barley or rye than a camel can manage to carry.—(*Krapf's Travels in Eastern Africa*.)

OUR LETTER BOX.

WARTS (D. K. B.).—We have cured hundreds by touching the tops of them with nitric acid. This turns them yellow. After two or three days the stained part is easily scraped off. Then touch them again with the nitric acid, and continue the treatment till the warts disappear. Do not apply the nitric acid to any wart that is tender, or to one that has recently bled.

MANAGEMENT OF SPANISH FOWLS (Adelaide B.).—Spanish fowls do not require different treatment from others, and we will, therefore, gladly give you the information you require, by telling you that which we believe to be fit and proper for all fowls. The quantity of food given by hand must always be regulated by that which is to be had naturally, and there is a very easy method of ascertaining the exact amount, which is, by feeding only so long as the fowls show they want it. Take ground oats, slake them with water, and when they have reached the consistence that they will retain the form given to them, but break on falling, then throw small pieces, size of small nuts, on the ground. As long as the fowls run after and eat these, continue to feed; when they cease to do so, leave off feeding. You may be satisfied they will eat as long as it is necessary for them. There is not only health and condition, but there is great economy in this system. All yards are badly conducted where food is to be seen lying about—it is fatal to health and profit. Ground food is better and more economical than whole corn. The noise like a cough emitted by the hen is probably caused by a slight cold, or it may arise from something lodged in the throat. Spanish are not subject to roup, and, therefore, this symptom has not the importance it has in other breeds. If it continues, separate the bird from the others, and use a stimulating diet, such as bread and beer, or wine. Buy "The Poultry Book for the Many," published at our office.

BUTTER, STRONG-SMELLING (A Subscriber).—Washing butter in a water in which a little chloride of potash has been dissolved, and then in water only, will often remove the flavour arising from the cows eating weeds.

FUR OF ANGORA RABBITS (—).—A pure-bred Angora Rabbit should show length of fur from the first, but they do not arrive at perfection till about six or eight months old.

WEIGHT OF PRIZE DOE (Orion).—You had better communicate with Mr. Charles Sellen, as we do not know the weight of the doe that took the prize.

BEES BY POST.—Mr. Wm. Eaglesham, of Stewarton, will oblige by stating if the Ligurian workers sent to him by Mr. Woodbury were alive when they reached their destination.

LONDON MARKETS.—JUNE 3.

POULTRY.

We are gradually getting into a better state of things; the supply is increasing, and with it the trade assumes a healthier character. The supply will soon be equal to the demand.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 72.2° and 49° respectively. The greatest heat, 97°, occurred on the 16th in 1858; and the lowest cold, 30°, on the 15th in 1850. During the period 140 days were fine, and on 98 rain fell.

ARRANGING FLOWERS IN BOUQUETS AND VASES.

(Continued from page 172.)

MECHANICAL WORK (Continued).

TURNING again to our mechanical descriptions for arranging flowers, flatness, it must be remembered, is a great secret of success, so that in a vase or group the curve should really be very slight indeed, and the flowers carefully kept down to the proper level. Having provided the frame, the next thing is the preparation of the flowers. If they are for a dish or vase, and if this dish or vase is opaque and can be filled with wet sand, nothing else answers anything like so well. If water must be used, a few large pieces of charcoal are very good preservatives from its being disagreeable, and this is far better than charcoal dust—the latter causing so much dirt and extra trouble. The lumps may be employed for an indefinite length of time, and can be washed whenever

needed without inconvenience.

If sand is used it should, between each using, be thrown into a heap on a tray in the sunshine, to dry and sweeten, and then it should be sifted.

The dish being filled with a heap of sand, fitting under the frame—or a heap of sand would do quite well without a frame at all—the flowers will need no preparation beyond that of cutting off all the foliage up to the point which is to be above the frame or sand, and shortening, if necessary, parts of stalks which are too long.

If the bouquet is for the hand the flowers will, many of them, need mounting—that is to say fastening upon longer stems, which is a separate branch of our little art, and will be treated of separately another day. In this case also, the leaves of all will require removing till they are only left where they grow above the wire level. The frame should now be filled up with green leaves, this having the effect of preserving the flowers longer, and of preventing bareness when they do drop off.

Scarlet Geranium leaves are amongst the very best; but all Geranium leaves are good for this purpose, unless their scent should sometimes render them unpleasant. The Fair Helen, and, I think, the common Oak-leaved are very unpleasant to most people, having such a very strong and unfresh smell. The Ivy-leaved Geraniums, also, though at the first moment one hardly observes it, quite spoil any bouquet by their sickliness when torn or gathered. Of the Spice-scented Geraniums there is one

very small and cut-up-leaved kind with a delightful and very delicate perfume like lemons, which is amongst the most desirable. Myrtle is one of the best kinds of foliage to put near the edge, as even the slight pressure from a touch so much brings out its fragrance. Sweetbriar and sweet Verbena (or Lemon plant) both so delightful, are apt to look disfiguringly untidy; and they are, therefore, far the best placed just underneath the frame, where they are reduced to the compulsory modesty of wasting unseen their sweetness, though not, we hope, "upon the desert air." For myself, I far prefer to any other a thick coating arranged in regular rings of nice, crisp, velvety Geranium leaves, or of other evergreens, and they are none the worse for dipping and agitating under water, as then the foliage is apt to retain some moisture. Young green shoots of other shrubs and plants are always bad, however, as their flagging so soon gives a faded look to all.

For arranging the foliage a long white piece of Berlin wool should be tied to the wire stick, and each separate leaf, if too short to be bound to the centre stalk-wire, should be caught in by that wool. The coat of network formed by the crossing threads of wool causes no harm at all, or rather is useful than otherwise as retaining moisture.

A little trouble and observation are necessary here, as in everything else that is worth doing. Some leaves will hardly ever fall from their own stems: while others, like Begonias, which are so very beautiful, are by no means unapt to drop away entirely, much to the injury of the place they leave. I always, therefore, think it safest to fasten, for instance, the Begonia footstalks separately: a small piece of the thin green flower-wire, to be bought at all wax-flower makers, answering well for keeping them all safe.

It is a vexed question whether flowers arrange better when the arrangement is commenced from within or from without. I believe for dishes and vases there is no doubt that beginning from the outside and working inwards is the best plan, laying a frill of leaves at the edge at first, arranging first, as just described, all the leaves required for the lining. But for flowers for carrying in the hand I think the central commencement is best: it is almost impossible otherwise to secure the stalks sufficiently firmly to keep them in their places.

For these, therefore, beginning at the central flower or green, it is better generally to carry the wool separately round each separate flower as it is wound on, going straight round the bouquet; and here a little knack is wanted to turn it evenly round and to keep up the proper level.

In mixed arrangements, of course, there is a constant exercise of one's own taste, and of the correctness of one's eye for colour; but I think there are few cases where it is not safer to begin by excluding from the basket all the flowers which common sense assures us never, under any circumstances, can really harmonise. When we are actually arranging we are not fair judges—because a very lovely pink flower is so pretty; and what

harm can it do to put in that charming Rose? But when the scarlets begin to gather thickly we sometimes regret that we were not more difficult to be tempted. In that case it still is possible to correct the mistake by cutting the flower off short, and forcing a mounted one down on a piece of stick; but still, as such tempting flowers are generally the prettiest, it is a pity, and we wish they were once more back upon the tree.

I need not go on, however, writing of these arrangements now, as those following apply also to them, and we have to give such minute directions for them in the designs so often. I will only add, therefore, that it is always necessary to bear in mind what follows after as well as what goes before in respect of colours.

For the vases, &c., when arranging the flowers in them, it is very essential, if the flowers are large, that no two flowers, or sprays of foliage, should be exactly over each other's heads, so as to give the slightest appearance of streakiness or of formal lines. A circle having been formed all round the outer edge, whether of different colours or of a single colour, the flowers or leaves should be carefully arranged in the second row, so as to come between each two rather than over any. The number, therefore, of the first row should be uneven; and afterwards, if the flowers are large, between every two others may in some rows be sufficient for placing the succeeding flower; the length of each row, of course, shortening so materially as it approaches towards the middle.

Drooping flowers have a very pretty effect, and they will often serve to break the formality of lines like these.

No Fuchsia should, however, ever be used in bouquets to be carried. The flowers drop so readily, and are so invariably crushed if drooping; yet, if prevented from hanging in their natural most graceful position, they look most painfully out of place and keeping.

Heliotrope should rarely be used, because it turns black so soon. Nemophila never, for its flowers, like the Fuchsia, speedily tumble off.

Chinese Honeysuckle is charming for breaking with its foliage the formal rows. So is the pretty Ribbon and Feather Grass. So are Ferns especially, and evergreen Rose leaves also. Nor must I omit little sprays of Clematis; nor those of Asparagus, nor even the small leaves of the common Carrot! Few botanists even recognise by their eye the foliage of these two kitchen-garden plants when introduced in bouquets.

VASE DESIGN.

I will now give a few hints for vases of Verbenas, which may be made very brilliant, though in this case it should be a pattern device, the flowers themselves not being of a very graceful outline. Useful flowers they are, for from June to November any garden can be well supplied with them. Heavy rains, indeed, do sadly dash their brightness, but an awning or a few bell-glasses can always preserve many blooms in beauty.

I think for Verbenas a rather stiff arrangement is almost inevitable. They may be divided into points. A white ground looks very well, with the encircling points shaded from crimson into the very palest pink, and then with a centre again all shaded down at the edge to the very faintest blush.

Some persons make points of varying shades, as if, for instance, there are sixteen, they would have the first and ninth of the darkest possible tinge; the second, eighth, tenth, and sixteenth the next darkest; the third, seventh, eleventh, and fifteenth the next; the fourth, sixth, twelfth, and fourteenth the lightest except one; and, lastly, the fifth and the thirteenth the very lightest possible.

The flowers are in all these filled as closely as possible into the frame of card, and are even mowed off—I cannot find a better word—with a sharp knife or scissors up to the exact edge thus indicated.

There may be a thin line all round of white, and a very dark purple or very pale mauve ground, or there

may be a white ground only, intervening between the inward-pointing edge and the centre similarly arranged with the same number of points pointing exactly to, or in between, the others.

The green for these Verbenas is difficult to select. I think that Geranium leaves do as well as any, and sometimes, perhaps, an edging of Geranium foliage coming a little way over the edge might have just underneath it a row of drooping Fuchsias, harmonising in colour with the Verbenas, and at the same time giving in some degree the grace of form they want.

In this case the lighter Fuchsias should correspond with the darker points, and the darker Fuchsias with the light Verbenas. The shades not being likely to exactly match, this reversal is far preferable to having the contrast brought more prominently forward.

The Fuchsias and Verbenas that are to be used by candlelight should always be previously *tried* in that light. Sometimes the white Fuchsias look so very dead, and always doing so if there is the faintest tinge of green about their petals, and the Verbenas sometimes appear extraordinarily dull; as the purple flowers look slaty or nearly black, while the crimson flowers take a deeply purple hue.

The pale mauve, too, varies much: but when the exact shade which retains its proper delicate appearance can be found out, it is a very pretty and very soft-looking ground to what may be made an extremely brilliant and tasteful group.—E.

(To be continued.)

THE OPENING OF THE ROYAL HORTICULTURAL SOCIETY'S GARDEN AT SOUTH KENSINGTON.

ON Wednesday last was exhibited one of those grand spectacles which this country alone can produce. It was an event in the history of gardening and of the Horticultural Society, which will be long remembered by those who witnessed it, and which will form a red-letter day in every future gardening calendar. Her Majesty, accompanied by the Prince Consort and the Princess Alice, honoured the Garden with a private inspection early in the day; and among the early visitors we observed, after the doors were opened, Queen Amelia, the Duc and Duchesse de Nemours and suite. All the Members of the Houses of Lords and Commons received cards of invitation from the Council; and to judge from the well-known faces one met at every turn, certainly three-fourths must have availed themselves of this courtesy, and, as a matter of course, the ladies of the Members of both Houses were present also. Shortly after four o'clock, His Royal Highness the Prince Consort, President of the Society, accompanied by His Royal Highness the Prince of Wales, Her Royal Highness the Princess Alice, Her Royal Highness the Princess Helena, Her Royal Highness the Princess Louisa, His Royal Highness the Prince Arthur, Her Royal Highness the Princess Mary, His Royal Highness the Duke of Cambridge, His Royal Highness the Count de Flandres, His Royal Highness Prince Louis of Hesse, On arriving at the grand entrance they were received by the Vice-Presidents and the Council, and the Royal Commissioners of the Great Exhibition. In the great meeting-hall the Fruit and Floral Committees were assembled along with the other Committees afterwards mentioned. About half-past four o'clock a procession was formed, and, leaving the great hall, marched the whole length of the Garden to the centre entrance of the grand conservatory, the ground being kept by the 1st Middlesex Engineer corps. On issuing from the great hall into the grounds, the band played "God Save the Queen," and during this the Royal party grouped themselves on the arcade steps, while a photograph was taken of the whole party with the utmost success. This done, the procession moved forward in the following order:—

Foremen of Gardeners.

Mr. William Dennis, Mr. John Gubbins,
Mr. William White, Mr. Jessie Eyles, Mr. Arthur Bick.

Foremen of Works.

Mr. Wilkinson, Mr. Bone (Bricklayers), Mr. Cross, Mr. Forbes (Masons),
Mr. Muspratt (Carpenter), Mr. Hindley (Iron), Mr. Rodford (Plasterer),
Mr. John Clark (Navigator),
Mr. C. F. Harrison, General Superintendent.

Clerks of the Works, Draftsmen, &c.

Mr. Scott, Mr. Townsend, Mr. Grover,
Mr. Snell, Mr. Liddell, Mr. Wakeford, Mr. Godfrey Sykes,
Mr. Taylor.

Contractors.

Mr. Blanchard, Messrs. Forrest & Sons, Messrs. Minton.
Messrs. Easton & Amos, Mr. Weeks, Messrs. Anstin & Sealey.

Assistant Secretary.

Mr. Andrew Murray, F.L.S.

Superintendent of Garden.

Mr. Eyles.

Auditors.

Mr. Jonathan Clark, Mr. Edward Rosher, Mr. George Paul.

Members of the Floral Committee.

Mr. Thomas Moore, F.L.S., *Secretary.*

Mr. William Barnes, Mr. Donald Beaton, Mr. W. B. Booth, Dr. Bashell,
Mr. John Cook, Mr. J. Cuthbert, the Rev. H. H. Donbrain, Mr. John Fraser,
Mr. Richard Headley, Mr. A. Henderson, Mr. W. Holmes, the Rev. D. R. Hole,
Mr. James Ivory, Mr. J. Keynes, Mr. F. R. Kinghorn, Mr. Charles Lee,
Mr. M. T. Masters, Mr. Robert Parker, Mr. A. Parsons, Mr. William Paul,
Mr. John Salter, Dr. Sankey, Mr. George Smith, Mr. J. Standish,
Mr. Charles Turner, Mr. Harry J. Veitch, Mr. R. Warner.

Mr. James Bateman, *Vice-Chairman.* The Rev. J. Dix, *Vice-Chairman.*

Members of the Fruit Committee.

Mr. Robert Hogg, LL.D., F.L.S., *Secretary.*

Mr. H. Bailey, Mr. H. G. Bohn, Mr. M. Busby, Hon. and Rev. F. Curzon,
Mr. D. Cunningham, Mr. F. Dancer, Mr. W. Hill, Mr. T. Ingram,
Mr. J. Jessop, Mr. S. Mart, Mr. H. Meyers, Mr. W. Myatt,
Mr. John Newton, Mr. Joseph Newton, Mr. W. J. Nutting, Mr. Robert Osborn,
Mr. John Peel, Mr. A. Scrutton, Mr. J. Spencer, Mr. C. W. Strickland,
Mr. Thomas Taylor, Mr. G. Tillyard, Mr. Robert Thompson, Mr. J. B. Whiting,
Mr. F. J. Graham, *Vice-Chairman.* Mr. Thomas Rivers, *Vice-Chairman.*

Members of the Implement Committee.

Sir Joseph Paxton, M.P.; Mr. Edward Easton, Mr. B. T. Brandreth Gibbs,
Colonel Challoner.

Members of the Works Committee, &c.

Mr. John Kelk.

Mr. Sidney Smirke, R.A.; Mr. W. A. Nesfield, Mr. H. A. Hunt,
Mr. Henry Cole, C.B.; Capt. Fowke, R.E.; Mr. R. Redgrave, R.A.

Members of the Fine Arts Committee.

Mr. Richard Westmacott, R.A., Sir Conds Lindsay, Bart.,
Lord Llanover, Earl Somers, Earl Gifford.

Her Majesty's Commissioners for the Exhibition of 1851.

Mr. E. A. Bowring, *Secretary.*

Mr. H. Thring, Mr. Leonard Horner, P.G.S., Mr. T. Field Gibson,
Mr. T. Fairbairn, Mr. Cobden, M.P., Mr. Bidder, P.I.C.E., Mr. Bazley, M.P.,
Mr. T. Baring, M.P., Sir R. I. Murchison, Sir C. Lyell, Sir C. L. Eastlake, P.E.A.,
Sir S. Morton Peto, M.P., Bart., Sir Alexander Spearman, Bart.,
The Right Hon. Robert Lowe, M.P., the Right Hon. W. E. Gladstone, M.P.,
The Rt. Hon. T. Milner Gibson, M.P., the Rt. Hon. B. Disraeli, M.P.,
The Rt. Hon. W. F. Cowper, M.P., the Rt. Hon. Sir G. C. Lewis, M.P.,
Lord Taunton, Lord Overstone.

Viscount Palmerston, K.G., M.P., the Earl of Derby, K.G.

The Marquis of Chandos, the Duke of Buccleuch, K.G., Earl Granville, K.G.

Council of the Royal Horticultural Society.

Mr. John Lee, Mr. Edmonds, Mr. Wrench, Mr. James Veitch,
Mr. S. H. Godson, Mr. Henry T. Hope, Mr. John Clutton, Mr. J. F. Pownall,
Mr. Wilson Saunders, *Hon. Treasurer.* Dr. Lindley, *Hon. Secretary.*

Vice-Presidents of the Royal Horticultural Society.

Mr. J. J. Blandy, Mr. C. Wentworth Dilke, the Earl Dacie, the Lord Bishop
of Winchester.

H.R.H. the Prince Consort, the President of the Society.

H.R.H. the Prince of Wales.

H.R.H. the Princess Alice.

H.R.H. the Princess Helena.

H.R.H. the Princess Louise.

H.R.H. the Prince Arthur.

H.R.H. the Duchess of Cambridge.

H.R.H. the Princess Mary.

H.R.H. the Duke of Cambridge.

H.R.H. the Count de Flandres.

H.R.H. Prince Louis of Hesse.

Suite.

Police.

After the procession began to move, the bands of the Volunteer
Engineers struck up the "Coburg March," which was suc-
cessively taken up by the bands of the Life Guards in the upper
garden as the procession approached.

On the procession arriving in front of the great conservatory,
the Royal party took up their position on the landing of the
centre entrance, and Dr. Lindley, the Secretary of the Society,
read the following address:—

"May it please your Royal Highness,—Sir, we, the Council of
the Royal Horticultural Society, venture to congratulate your
Royal Highness upon the important stage at which we have now
arrived in the progress of an undertaking originating with your
Royal Highness, and in which you have continued to take so
active an interest—an undertaking for the establishment at the
west end of this metropolis of a noble Garden, by the aid of
which, and of the Society's Gardens at Chiswick, not only the
art of horticulture may be effectually promoted, but an additional
means of enjoyment and recreation may be afforded to the dense
population of London.

"We deeply lament that recent domestic affliction should have
deprived us of the honour, for which we had been encouraged to

hope, of the presence of our gracious Queen at this inaugural
ceremony. But whilst we deeply feel the want of that presence
which would have added the greatest lustre to the day's pro-
ceedings, we are sensible of the many marks of Royal favour
which we have already received, and trust that these Gardens
may, when completed, prove not altogether unattractive to Her
Majesty.

"Horticulture, Sir, is the parent of agriculture. It determines
on a small scale the value of the principles on which an extended
cultivation of the soil depends. It is associated with our food,
our wealth, and many of our social enjoyments. Your Council
believe that this Society has already contributed largely to the
establishment of the sound principles on which cultivation is
founded. In the course of the last half century the Society has
unremittingly used its influence and its means to enlarge the skill
of the gardener and the taste of the community. It has had the
good fortune to see, during that long period, many ornamental
plants and every race of fruits and esculents undergo great im-
provement; and it is not too much to assert that its labours have
raised English gardeners to the highest rank.

"Founded in the year 1804, and incorporated in 1809, by
command of His Majesty George III., the Society, after languish-
ing for some years, sprang into active existence as soon as the
termination of the long war once more left men leisure to cul-
tivate the arts of peace. At that time horticulture had ceased
for many years in every part of Europe to make sensible progress.
All that remained was an unintelligent routine. Up to the year
1816, the number of Fellows who joined the Society annually
rarely exceeded twenty. From that period, however, the
elections rapidly increased; so that in 1821 they amounted to
328. In 1822, the Garden at Chiswick had been formed and
the power of the Society to do good began to be felt even in the
remote possessions of the Crown. Collectors of seeds and plants
for the Horticultural Society were heard of in the United States
and Canada, in India, on the banks of the Zambesi, and in the
distant regions of the Hudson's Bay Company. The result of
these operations was the introduction into England of by far the
larger part of the highly-prized occupants of modern gardens.

"In 1827 was held the first of those fêtes, or, more properly,
exhibitions of horticultural produce, which for so many years
were among the most attractive events of a London season. At
first these meetings were attended with little success; there now,
indeed, remains in the Chiswick Garden, the small iron tent
under which a few cultivators ventured in those days to display
their scanty stores. But liberal rewards produced competition;
gardeners soon saw that to be the gainer of a prize at Chiswick
was to stand at the head of their class; knowledge was sought
for, and improved methods of cultivation were gradually dis-
covered.

"The changing habits of society, the competition of other
similar exhibitions in London itself, the power of locomotion to
more distant places of recreation by railway, combined with the
at-all-times-uncertain nature of our climate, had in late years
materially diminished that attendance of visitors upon which the
income of the Society, and, consequently, its power of encourag-
ing horticulture, depended. It was under these circumstances
that an opportunity of forming a garden in the immediate
vicinity of the metropolis was sought.

"Her Majesty's Commissioners for the Exhibition of 1851, of
whom your Royal Highness is also the President, having pur-
chased out of the surplus funds of that undertaking an estate at
Kensington Gore, it was felt that this locality offered unrivalled
facilities for the establishment of a new Garden, and successful
negotiations with the Commissioners enabled the Council, with
your Royal Highness's sanction, to lay, in July, 1859, the plans
before the general meeting of Fellows, which received their unani-
mous approval.

"An agreement has since been concluded by us with Her
Majesty's Commissioners for leasing a space of 22½ acres upon
a rent, the amount of which is contingent upon the income of
the Society; part of the conditions being, that the Society should
expend on the Garden a sum of not less than £50,000, Her
Majesty's Commissioners binding themselves to enclose it with
arcades of an ornamental character, costing at least an equal
sum. Her Majesty has been graciously pleased to grant the
Society a new charter of incorporation under the name of the
'Royal Horticultural Society.' Our works have not arrived at the
state of completion which we had hoped to have attained by this
time. Taking into consideration, however, the long-continued
wet of last summer, the unusual severity of the subsequent

winter, and the disturbance in the building trade caused by the unfortunate strike of this spring, we cannot but congratulate ourselves upon what has already been achieved.

"The necessity of pressing forward the works will prevent the Garden being as immediately accessible to the public as is hereafter proposed. But the Council felt that the admission of the Fellows and their friends, who have so zealously come forward in support of the undertaking, ought not to be longer delayed. They therefore resolved to hold exhibitions of flowers and fruit in the months of June, July, September, and November of the present year, to admit Fellows and their friends daily, and to allow a certain number of the public to visit the Garden on Saturdays. It is expected that before the ensuing spring all the essential parts of the Garden will be completed. When that time shall have arrived the public will be in possession of a place of resort in which not only may be displayed in the most advantageous way all that horticultural skill can accomplish, but whatever may most conduce to the improvement of public taste in sculpture and its sister arts.

"Since the period when your Royal Highness condescended, as President of the Society, to take an active part in its proceedings, it has enjoyed uninterrupted prosperity. At least 1500 new members have joined it; so much confidence has been placed in the measures of your Council as to have produced, by the issue of debentures, the sum of £50,000 required to meet the Society's engagements with her Majesty's Commissioners; and the Garden in which we are now assembled, itself, Sir, in many respects, the offspring of your own intelligence, has sprung into existence. When the trees shall afford a grateful shade, and the water works in progress shall have been completed, the scene cannot fail to be one of great interest and beauty. Even now the noble arcades, which are three quarters of a mile in length, will afford an agreeable and sheltered promenade in all weather, and the beautiful conservatory before us will be enjoyable in even the severest season.

"Nor can we look upon the various works around us without acknowledging how much we owe to the different gentlemen who have contributed so much genius and skill as well as valuable time to their design and execution.

"In the name of the Society we have the honour to represent, we therefore desire to express to your Royal Highness our earnest hope and confident belief that the formation of this Garden will show that it is not unworthy of the exalted patronage it has received from Her Most Gracious Majesty and your Royal Highness."

To this address the Prince Consort replied as follows:—

"I thank you for the address which you have just presented to me.

"While you have expressed your deep regret at being deprived, on this occasion, of the presence of the Queen, I am enabled and empowered to assure you, that her Majesty, on her part, also sincerely regrets her inability to mark by her presence the interest she takes in your proceedings, and her desire for your success.

"You have addressed me in my double capacity of President of your Society and also of the Royal Commissioners of 1851. In either of these capacities, I cannot but be gratified by the scene now before me.

"Having shared to some extent in your labours and anxieties, I am happy to be able to congratulate you on what has been effected in so incredibly short a time, notwithstanding the difficulties to which you have alluded, and which appeared at times almost to forbid hope of success.

"That, which last year was still a vague conception, is to-day a reality; and, I trust, will be accepted as a valuable attempt, at least, to reunite the science and art of gardening to the sister arts of architecture, sculpture and painting.

"This union existed in the best periods of art, when the same feeling pervaded and the same principles regulated them all; and if the misuse and misapplication of these principles in later times have forced again upon us the simple study and imitation of Nature, individual arts have suffered by their disjunction, and the time seems now arrived when they may once more combine without the danger of being cramped by pedantic and arbitrary rules of taste.

"The Commissioners of 1851, whose mission it is to encourage the arts and sciences as applied to productive industry, gladly welcome your Society as one of the first of those bodies devoted to the promotion of special branches of these arts and sciences that has availed itself of the enlarged means of development

offered by the Commissioners on their estate. They are glad to find in your present success, and in the generous support of the public, the confirmation of their belief that, in securing space on which, in unison with each other, and with a systematic interchange of mutual assistance, separate societies and departments might attain to a degree of usefulness which their present confinement and isolation must materially lessen, the Commissioners had correctly appreciated the great want of the day and the requirements of the public, for whose benefit alone they should work, and by whose assistance alone they can hope to prosper.

"We already see to the south, rising, as it were, by magic, the commencement of a noble work, entirely the result of the voluntary efforts of that public; and this Garden, itself the offspring of the Great Exhibition of 1851, will hardly be completed ere that Exhibition shall have been rivalled, and, I trust, even surpassed by the beauty and success of that which we hope next year to witness.

"This Garden will then open an additional source of enjoyment to the thousands who may be expected to crowd the new Crystal Palace of Industry. Nay, we may hope that it will, at no distant day, form the inner court of a vast quadrangle of public buildings, rendered easily accessible by the broad roads which will surround them—buildings where science and art may find space for development, with that air and light which are, elsewhere, well nigh banished from this overgrown metropolis.

"If the works before us are still incomplete, this must not be attributed entirely to the short space of time allowed for their execution, or to the exhaustion of the funds set apart for them. It results also, in great measure, from a well-considered purpose on the part of the Society and the Commissioners rather to present the public with a framework, to be gradually filled up as individual taste, controlled and harmonised by the general superintendence of the authorities, might direct, than at once to display a complete creation, which, however attractive for the moment, would pall upon us and grow stale by habit.

"Unrivalled opportunities are here offered for the display of works of art, and for the erection of monuments as tributes to great men and public benefactors. The memorial of the Exhibition of 1851, the result of private subscriptions, will be the first received in these grounds; and, adorned with a statue of the Queen, will soon rise in the centre of the Garden.

"May your efforts meet with public approbation! May that approbation give you all the support required, not only further to ornament these Gardens, but also to carry out, even on a larger scale than during the last forty-eight years, the useful objects for which you are incorporated!"

The addresses over, the Bishop of London, attired in his robes, advanced to offer up a prayer for the future success of the new Gardens. His Lordship was attended by the Ven. Archdeacon Sinclair, M.A., as Archdeacon of Middlesex and Vicar of Kensington, and by the Rev. Andrew Ramsay Campbell, M.A., Rector of Aston, Yorkshire, as his attendant chaplain.

The prayer had been specially composed for the occasion by the Bishop of London at the Royal request.

"Collect for the Day."

"O God, the strength of all them that put their trust in Thee, mercifully accept our prayers; and because, through the weakness of our mortal nature, we can do no good thing without Thee, grant us the help of Thy grace, that in keeping of Thy commandments we may please Thee both in will and deed; through Jesus Christ our Lord. Amen.

"Prevent us, O Lord, in all our doings with Thy most gracious favour, and further us with Thy continual help; that in all our works begun, continued, and ended in Thee, we may glorify Thy holy name, and finally by Thy mercy obtain everlasting life; through Jesus Christ our Lord. Amen.

"O Lord, show Thy mercy upon us,

And grant us Thy salvation.

O Lord, save the Queen,

And mercifully hear us when we call upon Thee.

Endue Thy ministers with righteousness,

And make Thy chosen people joyful.

O Lord, save Thy people,

And bless Thine inheritance.

Give peace in our time, O Lord,

Because there is none other that fighteth for us, but only Thou, O God.

O God, make clean our hearts within us,

And take not Thy Holy Spirit from us.

"O Lord, our Heavenly Father, who, when Thou madest man at the first, didst place him in the Garden of Eden, his home in the days of his innocency, look down upon us, who, in the midst of our sin and misery, would recall the thought of that pure and happy estate from which we have long since fallen. We thank Thee, O Lord, for the relics of Eden which Thou hast still left to us. We thank Thee that the weariness of our earthly pilgrimage is cheered by sights, and sounds, and odours—faint images of a beauty not of this earth. We thank Thee for the seeing eye, and the hearing ear, and all the enjoyments of sense and feeling. Teach us, O Lord, so to use all the relaxation Thou hast provided for us in the midst of our business and our sorrows, that, by the Holy Spirit's help, we may be growing fit to enter into the beautiful abode which Thou hast prepared for Thy redeemed, where sorrow is unknown, and the only business is to glorify Thee. O Lord, purify our hearts by the enjoyment of needful rest, and kindly Christian intercourse, and the soothing contemplation of all the charms which Thou hast given to Nature and to Art. Teach us to rise from the sight of present, and the memory of past pure enjoyments, to bright hopes of the restoration of all things in our Lord and Saviour Jesus Christ. Grant, Lord, that this city in which we dwell may be purified from the sins which deform it and their many pollutions. Guide us each to take his part in helping those around us to live Christian lives, that thus we, and all whom we can influence, may be waiting and longing for that holy city, the new Jerusalem, where is the pure river of the water of life, and the tree of life, whose leaves are for the healing of the nations; where there shall be no more curse, but the throne of God and of the Lamb shall be in it, and Thy servants shall see Thy face, and shall reign with Thee for ever and ever; through Jesus Christ our Lord. Amen.

"Our Father which art in Heaven, hallowed be Thy name. Thy kingdom come. Thy will be done in earth as it is in Heaven. Give us this day our daily bread. And forgive us our trespasses, as we forgive them that trespass against us. And lead us not into temptation, but deliver us from evil. For Thine is the kingdom, the power, and the glory, for ever and ever. Amen.

"The peace of God which passeth all understanding, keep your hearts and minds in the knowledge and love of God, and of his son Jesus Christ our Lord; and the blessing of God Almighty, the Father, the Son, and the Holy Ghost, be amongst you and remain with you always. Amen."

His Royal Highness then advanced to the front of the conservatory, and, taking off his hat, formally declared the Horticultural Gardens opened, amid loud cheers.

The procession then moved forward in the same order to the east end of the terrace, when the Prince went through the formality of planting a *Wellingtonia gigantea*, given by Messrs. Veitch & Son. It was a very fine young tree of eight years old, about 7 feet high, and, for its size, with a very thick stem and bark. The ceremony, if such it may be called, was soon completed, and the Royal party, after devoting half an hour to an inspection of the Flower Show, and more especially to the collection of Orchids in the conservatory, partook of refreshments, and quitted the grounds shortly after six o'clock.

The Duchess of Cambridge and the Princess Mary, having begun their tour of observation before the ceremony, were, as a natural result, so tired when all was over, that they preferred to depart by the nearest exit.

Before leaving the grounds all the Members of the Royal Family inscribed their names on illuminated sheets of paper, which were immediately framed and hung up for general inspection. We have the loyal satisfaction of saying that the little Princesses write very prettily indeed, dotting their i's, crossing their t's, and looping their long letters with exemplary precision. The names Alice, Helena, Louisa appeared severally on three blossoms of heartsease, all in a row; Arthur, in a determined round hand, came by himself in a spacious blank.

THE EXHIBITION.

THIS will be a memorial day in the annals of gardening. From the day Mr. Sabine took up the spade at Chiswick, to the planting of that *Wellingtonia* on the 5th inst. by the Prince Consort, immediately after he had opened the new Garden and declared it to be the inner court of a vast quadrangle of public buildings where science and art may find space for development, the

science of our craft found small space for developing the energies of the practical mind of gardeners; and practically, we had no leader for the last forty years, otherwise we might have turned out more Paxtons, McIntoshes, Flemings, and Eyles, and other heads of sections of the circle than we have done. But let us be thankful, and hope that the next forty years will make up the difference; and that the heads of the different branches of the cultivators of the science, and of the practical part of the work before us, will unite their efforts, not only within the "vast quadrangle," but extend them to the land's end on each side of it, and to the limits of the great circle whose products and properties we are all interested in developing.

This commencement was on a magnificent scale, and every one from the highest to the most humble who contributed to the success of the opening scene, must have been well pleased at the result. All the arrangements were perfect as far as I could see and hear. There never was such an enormous stock of plants in one place before, and of such a description. In twenty-three years after the first experiment was tried of showing plants for their own sake instead of for their flowers, two-thirds of this vast gathering were of that very description; and some of those who were the foremost to laugh at the daft experiment of 1838, were laughing in my presence in these arcades at their own good luck and success in crowning the rival to the floral fancy, and you never saw another set of people more in harmony and more pleased with each other than we were.

The most extraordinary circumstance, however, connected with this step in the progress of our experiments, was a large collection of most welcome plants that were sent from Japan by Mr. Fortune expressly for this Exhibition. These Japan plants arrived in England on the Friday before the exhibition-day, and were in a fit and proper state for the exhibition tables—in short, as good specimens of cultivation as ever I remember to have seen exhibited by English gardeners in these very rare or very new plants. Indeed, I could name some plants at the Exhibition which came from within a short distance from the Garden, that were not so creditable to the growers as those sent over by Mr. Fortune were to the gardeners of Japan. These Japanese seem to have the very same style of taste in plants as ourselves, and also to have as good gardeners and as careful propagators as we could turn out. Mr. Staudish, of Bagshot, exhibited these plants, and, of course, he will set to and propagate and sell them as fast as possible.

Cyano-hyllum magnificum and *Dion edule* were the two most splendid plants there. One plant of *Aerophyllum venosum* was the greatest triumph of gardening there in growing specimen plants; it was in a first-prize collection of nine plants by Mr. Chilman. The best single specimen there, or anywhere else in Europe, I should think, was Mr. Warner's *Lælia purpurea* with thirty-six full-blown flowers on it. It was only the week previous that I was boasting of one at the Crystal Palace from Mr. Stone, which had eleven blooms on; and even at this grand Exhibition, two of the best *Lælia purpurea*s had each only eight flowers. The greatest success over the greatest difficulty in growing very rare plants, was Mr. Leach's exhibition of the *Disa grandiflora* growing exactly like a luxuriant native along the edge of some ditch where there were no commissioners for looking after the drainage and sewerage.

In my own favorite family of Ferns, *Gleichenia* is now the most favoured at the Exhibition, and I think every species of it was there; and every one who showed Ferns had more or less of the different *Gleichenias*.

The Fruit was most tempting, and the only part at the Exhibition that was not well arranged for. The fruit stand was an oversight—it was a double stand, with one side, or one-half in the shade, and facing the back wall of the arcade: of course, one-half of the fruit could not be seen well. The Pines were as good as usual. The White Grapes not quite ripe enough for a high-class dessert; the Black Grapes were never better seen in this globe. The Buckland Sweetwater, for which I risked my liberty three years back at the Crystal Palace, was by far the best White Grape there, and will be the gardeners' best friend in White, as the Hamburg has always been in Black. Ingram's Hardy Prolific Black Muscat is decidedly of the Black Prince section, and the very best of Grapes; and the Trentham Black is of the Hamburg race, and wore the best bloom of all the Black Grapes there. But I must put off the best part of the fruit tale till I have more time and room, adding only this remark on the grand new idea of giving prizes for dessert arrangement—that it turned out exactly as some of my patrons, from whom I

earn all about the fashions, colours, taste, fancy, and forget-nots, predicted to me months back; and I would be bound that nine out of every ten gardeners who saw these desserts in competition, did not understand even the meaning of the first-prize dessert. Why should we not have the three degrees of comparison in the dessert? And, surely, people would need to know for whom the dessert was intended before they could make a proper use of the dishes, fruit baskets, and their own brains. Nothing, at least, would puzzle me so much as to be told to dish up eighteen or twenty dishes of fruit for a party, without having some idea of whom the party consisted.

I began at the western arcades, and took the measure of the Show in yard steps as nearly as possible. The plant stages were in three broad steps, covered with green baize, and set up against the white of the back wall of the arcade, which was most telling to Ferns and all the fancy and fine-leaved plants; but the white of the back wall took off much of the glow of Pelargoniums and Rhododendrons: indeed, more so, as all the light is from behind the head of the visitor. Cover that part of the back wall with green baize and you spoil it much more. Too much of one shade of green for a ground colour to green leaves of all degrees of green, will not stand the test of good effect out of best flowers. Dark brown or dark oak colour I am told to a certainty is the best to put behind flowering plants when the pots stand on green cloth, or dark grey if the pots are on brown boards or mother earth. In front of the plant stage a space of 12 feet wide in gravel makes up the rest under the cover of the arcade.

The first 24 yards were of huge Ferns; then two rows of Rhododendrons, and 17 yards of Heaths; then 6 yards of fine-leaved plants, and 69 bouncing steps of Pelargoniums, which brought us on to the west end of the conservatory. Along the west end, the front, and across the east end of the conservatory, is a narrow shelf holding one row of large plants, or two rows of middlings, and three rows of comfortable plants not small, nor large, nor middling. One hundred and fifteen yards of that stage were devoted to plants, the rest to doorways and other ways. The whole of these 115 yards might be said to be filled with new plants, rare plants, or fancy novelties of some degree. Here the Messrs. Veitch, exhibited some of their rarest gems, and they were many and most abundant. Mr. Standish, stood across the east end with that collection of Japan rarities just mentioned, consisting of from forty to fifty specimens. Then the two firms of Hendersons, the Pine Apple and the Wellington heros, with all the fancy of their respective firms. Then Mr. Turner and Mr. Ivery with new Azaleas. Then Milne, Arnott, & Co., with their new Gloxinas, and three new rivals in the Messrs. Bull, Linden, and Verschaffelt; and, last of all, and biggest of all the rest, Mr. Warner's "Good Gracious" *Lælia purpurata*, and another which he calls after Mr. Day, who first bloomed it, *Lælia purpurata* Dayii. But I shall have them all in detail before I end.

Along the back of the conservatory stood a large portion of the vast assemblage of variegated Begonias, the whole of the Orchids, and of the specimen and collection of Roses, the new ones being on the front stage, and all these took up 70 yards of very wide stages, in three easy steps. Within the walk or front passage of the conservatory was a double stand for all the collections of stove and greenhouse plants, and for Azaleas, some Begonias, and for two large collections of Ferns—that of Mr. Williams, of the Paradise Nursery, being the best ever exhibited. He ought to write a book on them, as the one he wrote on Orchids, if only to tell how to pack and unpack for exhibition. Of these double stages there were 35 yards, leaving a gravelled space 18 feet or 20 feet wide between them and the back stage along the very back. In the very centre was a large circular stand cutting the scene in two—a wrong principle. Right and left of that circle—the last circumference of protection for Roses—stood a single file of all sorts and degrees of Wardian Cases, and miniature drawing-room greenhouses, stoves, and ferneries. Then out of the house, and into the east arcade, where the fruit was, Mr. Noble's, of Bagshot, beautiful Rhododendrons; then 89 yards of the largest and finest variegated and fine-leaved plants in the world, under pot and tub culture, the like was never before seen, 12 yards British Ferns, 6 yards tall Cacti, 6 ditto Melocacti, and other dwarfs of the prickly races, 4 yards or 5 yards of Calceolarias, 6 yards of seedling Pelargoniums, and others on the double stage, 2 yards Amaryllids, 4 yards with Mr. Williams' hardy variegated plants, and 6 yards of Mr. Salter's ditto, 12 yards of cut Roses from Mr. William Paul and Messrs.

Lane & Son, and many seedling novelties, among which a dwarf dark purple Nasturtium-looking *Tropæolum*, in the style of the Tom Thumbs, promised to be a first-rate and the first good bedder of that race. Mr. Smith had his new bedding *Calceolaria canariensis* there as the best of that brood. The single striped and double Petunias were very beautiful; one single light with red stripes, from Mr. Ferguson, of Stowe, was most striking, as were the pot Pansies from Messrs. Downie & Laird, and from Mr. Bragg. Mr. Dean, of Shipley, Bradford, had two boards of his Belgian Pansies, in cut blooms, very fine, and amongst them his large, light Princess Alice, to which we gave a handsome lift at the Floral Committee the week before.

The Fruit double stand was 18 yards long. Three bunches of the Buckland Sweetwater weighed 6 lbs. 4 ozs., and three of the Black Prince 8 lbs. 4 ozs., all from Mr. Hill, of Keele Hall. Thirty-one or two Pine Apples, twenty pots of Grapes, and two pairs of pot Grapes trained archways on the back wall, with twenty-nine bunches of Black Grapes from Mr. Saunders, gardener to Sir H. Meux, were set off that way better than any I ever saw exhibited. Her young Grace of Sutherland kept up the old charter in competing with Her Majesty with a full collection of eight dishes of splendid fruit. Mr. Henderson came out again in the old Fleming style; and Mr. Ingram was worthy of his name, and to give Her Majesty the first place. He had Black Hamburgh and Muscat Grapes, Smooth Cayenne Pine—a fine fruit, Peaches and Nectarines, British Queen and Prince Arthur Strawberries, May Duke Cherries, and Beechwood Melon. Mr. Henderson mounted Black Hamburgh and Black Trentham Grapes (the bloom on the latter inimitable), Smooth Cayenne Pine, Peaches, Nectarines, Black Circassian Cherries, and two dishes of Melons—the Trentham Hybrid White Flesh and the Trentham Hybrid Green Flesh, both of exquisite flavour; but I was round before the Judges, and did not see the prizes of any of the fruit.

But I must give you some idea of the new plants from Japan, and all along the front stage; for about collections, if you read over again the reports of the May shows for the last seven years and suppose you are reading of this Show, you will not be two plants behind the time you are reading. To begin at the beginning I must take the north-east corner of the house, and there were six huge pot-baskets with *Ætostichidi* under great glasses from Messrs. Veitch, and by the side of them three small plants of the purple Maple of Japan, *Acer japonica*; and from a large specimen of it from the Pine Apple Place Nursery, one could accept it as a rival to our purple Beech. Then three *Libocedrus tetragona*—the true source of the Alerce wood, of which you heard so much from the Spanish contribution to the first Crystal Palace in 1851. It is as upright as a dart, and of a lively green, and seemingly a very fast grower. Three plants of a new Silver Fir from Vancouver's Island; a very curious little *Thuja*; and three of a most curious *Cryptomeria japonica*—more like a *Retinospora* than a *Cryptomeria*, and an evergreen, a bedding plant with little green about it, but the most beautifully variegated plant, as like the variegated Periwinkle as you can draw it, and all the time a new *Euonymus*. Get a stock of this shrub, and all you will have to do to edge the ribbon after the planting is finished is to put in a row of cuttings of this very thing; every one of them will root so, and while they are doing that and for the rest of the season you have the very best variegated edging I can think of. The same plants will do half a dozen years, as the kind seems quite a dwarf. This, and Mr. Bull's *Agathæa* or variegated *Cineraria amelloides*, and Mr. Salter's *Veronica chamaedrys variegata* are three gems, take my word for it. How most strange it seems to call the dear old *Cineraria amelloides*, now termed variegated, by its true name, while the wrong old name would alone sell a thousand of it ere people can call to memory the new name—*Agathæa*, and then not know if it is the fashionable pronunciation! How often have I asserted that it is the best of all plants to keep in pots in readiness to fill up in a hurry, as all the soil can be shaken from the roots in the hottest day in July or August, and one watering after planting it so is sufficient to keep it unflagging.

After these stood the forty or fifty plants arrived from Japan on the previous Friday. What a fortunate man Mr. Fortune has been, that he can send from the ends of the earth plants fit for present exhibition. The Parasol Pine took my eye first—that is *Sciadopitys verticillata*; a fine variegated *Gordonia* sp., a variegated *Eurya* sp., a variegated *Osmanthus angustifolius*, like a genteel form of a silvery holly. The dwarf variegated Bamboo

in bunches, a new evergreen *Berberis*, several kinds of variegated *Camellias*, a variegated *Tea plant*, *Thea viridis*, two or three kinds of variegated *Podocarpus*, a variegated *Daphne*, ditto *Elaeagnus*, a green and a variegated *Retinospora* something, variegated *Illicium*, golden *Podocarpus*, *Thuopsis dolabrata* variegata—the finest variegated plant of the creation—nothing on earth can beat this for gemiferous looks; *Aucuba japonica* *femina* to cross and get seeds from at last, and a beautiful mate for the "*Magnolia spottifolia*" of Mr. Walter Dickson, and ever so many more of the same selections of garden gems which the Japanese value as much as we do our variegated *Geraniums* and other softwooded plants.

Next to these stood three more plants from the Messrs. Jackson, of Kingston—a fine-looking *Quercus bambusæfolia*, a long soft-leaved *Buxus* from Nepal, and *Juniperus drupacea*, a strong upright grower. Then some extraordinary queer thing growing in jointed flaps against a deal board, from Mr. Williams, of the Paradise Nursery, said to be from Manilla.

Then a collection of thirty-two kinds of most rare and ornamental plants from the Messrs. Veitch, consisting of *Selaginella atro-viridis* and *Lobbia*, also *conferta* and *caulescens*—as much like fine *Ferns* as *Lycopods*; *Lycopodium phlegmiana*—a tree *Lycopod*, *Lomaria falcata*—a miniature tree *Fern*, exquisite, and *Leptopteris superba*—a filmy *Fern* under a glass cap; *Sonerilas*, *Medullarium*, *Physurus*, *Sarracenas* of many sorts, *Campylobotrys*, *Gardenia radicans* variegata—a Japanese of course, *Ouvirandra*, the water-lace leaf of Madagascar, the Australian *Pitcher-plant*, *Cephalotus folicularis*, which stood out several winters in Cornwall with the late Sir William Molesworth, a *Venus' fly-trap* *Dionaea*—fine-looking and fine to the touch, *Maranta ornata*, with long upright footstalks to the handsome leaves, *Caladium Veitchi*, of the shine of *Alocasia*, and the *Adelaster albivenia* lately before the Floral Committee.

After these another collection from the same exotic growers—say *Selaginella Walliichi*, a *minosa-leaf-like* plant, a love of a thing; *Caladiums*, *Pitcher plants*, a fine *Pteris argyræa*, and *cretica albo-lineata*: *Caladium Bellemeyi* done to a T, also the *argyrites*; *Colocasia edulis* variegata, a splendid thing; and the *Alocasia metallica* with eight leaves, coloured as it is in "*The Illustrated Bouquet*," and not of that dark brown dusty out-of-the-world looks you sometimes meet with where the plant is starved with cold and wet.

Mr. Jackson followed up from Kingston with *Lonchitis aurita*, fine; *Colocasia antiquorum*, variegated and very fine; *Asplenium filix-femina*, a most delicate frizzly *Fern*; and a good *Pteris cretica albo-lineata*—the variegated *Fern*, which I am just going to compete with my variegated *Nosegay* out of doors.

Mr. Bull next, with a prickly-leaved *Hippomane*, like some *Brexia*, of which a huge plant was in a distant collection; *Campylobotrys* of sorts; *Theophrastia* ditto; a large *Lomaria heteromorphia*; *Araucaria Cunninghami*, new to me, and seems a robust thing; young *Palms* of sorts and other sorts of that run; and six plants of *Arthrotaxus Donni*; and a fine lot of *Agathæa cœlestis*, or the variegated *Cineraria amelloides*, getting better and better as the season goes on. Mr. Bull ought to make a fortune out of that one plant—the most useful plant and the easiest to grow and to keep you can think of.

Then a fine lot of upright *Gloxinias* from the Messrs. Smith, of Dulwich, and from Messrs. Milne, Arnott, & Co.; then a stumpy tree *Fern*, *Todea pellucida*, from Mr. Standish; then a large collection from Mr. Henderson, of Pine Apple Place Nursery, including the aforesaid large plant of *Purple Maple*, *Acer japonica*, a beautiful variegated *Yucca filamentosa*, and the bright silvery-leaved *Acer negundo*, and a variegated *Cobea scandens*. Then assortments of the newest *Roses*, of which *Evêque de Nîmes* was very choice, and the next two, *Madame Bonnaire* (H.P.) and *Triomphe de Lyon* (H.P.).

The collection from the Wellington Road Nursery succeeded; and here were the very fancy *Petunias*, double and single, plain and spotted, edged and striped, and of the liveliest shades of colour. What really nice things there are now in this one family! The very elegant basket plant, *Convolvulus mauritanicus*, with the light blue of the finest campanula, a love of a plant, just a lady's gem of a thing; *Caladiums* in all their spots; *Begonias*, ditto; *Chamæcyparis sphaeroides*, a new fine *Conifer*; *Blandfordia nobilis*, in good bloom; the *Bellemeyi Caladium* particularly good; *Lady Emily Peel*, the best of the *Shrubland Rose* breed of *Petunias*; *Sphærostema marmorata*, a fine climber; *Amaryllida*

and several others of the improved seedlings of garden plants then a huge plant of *Orchis foliosa*, with sixteen flower-spikes from Mr. Williams aforesaid; and a large *Dendrobium nobile*, from Mr. Hedge, Norwich Road, Ipswich, as you go out to Shrubland Park. Then the grand monarch of all this grandeur—the grand *Lælia purpurea* with thirty-six blooms on it, from Mr. Warner, who is one of our Committee, and was as deep in the procession as W is low in the alphabet, for we all went in for it, dictionary fashion. By it was the variety called after Mr. Day, who first bloomed it, and also a fine variety of *Cattleya*, which he calls after Mr. Fairrie, of Liverpool, for his blooming the kind for the first time. But at this point everybody I ever knew seemed to meet and wished to have a chat, so I may be wrong in Days and Fairries; but I threw away my book and ran out of the house, and I must find it before I go further.

D. BEATON.

MR. DILKE'S PRIZES.

C. Wentworth Dilke, Esq., offered prizes for the best designs formed of combinations of flowers and fruits, for the decoration of the dinner table. The competitions were very numerous, and occupied a table, 100 feet long, in the western arcade. The Judges were, the Countess of Ducie, the Countess of Shelburne, and Mrs. Holford, assisted by Professor Westmacott. The designs embraced every imaginable shape and form, from the tawdry and unmeaning groups you sometimes see at rural flower shows to the elegant and costly *eperges* of the metropolitan saloons. Most were of silver and crystal, richly cut, chased, and set; some of parian, porcelain, or earthenware, and some entirely of glass. Speaking generally, it was a most magnificent exhibition, and formed one of the most, if not the most, attractive feature of the whole. As was to have been expected, the most simple and elegant group was the most successful, and this was designed and supplied by Mr. Thomas C. March, of the Lord Chamberlain's Office, St. James' Palace; but the arrangement of the flowers and the fruit was the work of his sisters, Mrs. Henry Pickering and Miss March. The design consisted of a large crystal dish as a base, on which were placed three tall slender stems, each bearing a flat dish on the top. These dishes were ornamented with *Maidenhair Fern*, rings of *Forget-me-not*, *Lilies of the Valley*, *Lycopodiums* creeping up the stems, *Pansies*, *Rose-buds*, and small bunches of *Grapes* introduced here and there. The second prize was awarded to Lady Rokeby, the third to Lady Caroline Kerrison, and the fourth to Messrs. Elkington & Mason. Other exhibitions by Lady Emily Peel, Lady Trowbridge, and Mrs. T. Jones were highly commended.

THE FLORISTS' FLOWERS.

LEAVING to others to describe the grand ceremonial of the opening day, and the magnificent collection of stove and greenhouse plants, the waving *Ferns* of New Zealand and Australia, and the luscious fruits of all climes—relinquishing, with no small degree of regret, the task of describing the wondrous novelties sent home by Mr. Robert Fortune to Mr. Standish—yea, even abandoning the pleasant work of dilating on the contributions for Mr. Wentworth Dilke's prizes for ornaments for the now-fashionable dinners à la Russe, I must keep in mind *ne sutor ultra crepidem*, and, therefore, stick to my last—namely, the Florists' Flowers—the weakest point of the Exhibition without doubt. Some months ago I alluded to the subject in THE COTTAGE GARDENER, and said then the time was rather unfavourable, and that the schedule did not offer many advantages to the cultivators in that class. No prizes were offered for *Pansies*, *Pinks*, *Calceolarias*, or *Verbenas*; and though of all, save the second, stands were exhibited, yet there was not, of course, the incentive that the offering of prizes for them would have created. There was, moreover, the same miserable confusion about seedling flowers that there always is, perplexing the Judges, confusing the visitors, and, of course, dissatisfying the exhibitors; yet withal my often-expressed opinion was confirmed then as well as at other times—while the large collections of stove and greenhouse were comparatively unnoticed, the groups of visitors were concentrated around the *Pelargoniums*, *Pansies*, *Verbenas*, *Roses*, and *Fruit*. In the former the same old faces present themselves from the same exhibitors, while in the florists' class there is the charm of ever-increasing novelty.

The large ROSES in Pots occupied the centre of the great conservatory, distributing their fragrance around. The first prize (for fifteen) was awarded to Messrs. Lane & Son, for Jules Margottin (H.P.); Madame Plantier (H.C.); Comtesse Molé (H.B.); Madame Damaizin (Tea); Louis Peronny (H.P.); Paul Ricaut (H.B.); Le Lion des Combats (H.P.); Miss Clegg (N.); Coup d'Hébé (H.B.), a beautiful plant; Chénédole (H.B.); Blairii No. 2, very fine; Juno (H.C.); Gloire de Dijon (Tea), rather too full blown; Elize Mercier (H.B.).

The second prize was obtained by Mr. Wm. Paul, with Charles Duval; Bougère; Paul Perras; Paul Ricaut; Juno; Coup d'Hébé; La Reine; Auguste Mûr; Volours Episcopal (H.C.); Charles Lawson (H.C.), very fine; Duchess of Sutherland; Duke of Cambridge; Comte Boubart, fine large Rose; Madame Willermoz, very large and fine.

The third prize to Mr. Francis, of Hertford.

The first prize for NEW ROSES in small pots was awarded to Messrs. Paul & Son, Old Nurseries, Cheshunt, for Leonie Moise (H.P.), a miserably-shaped Rose, bright enough in opening, and then slating off; Madame Halphin (Tea), fine; Evêque de Nîmes (H.P.), a charming little rosette, though not deserving the name of a new Rose; Regulus, a bad Tea; Victor Verdier, a fine Jules-Margottin style of Rose; Buffon (H.P.), a very sweet colour at first, but very soon dying off; President (Tea), very fine; Admiral Nelson (H.P.), rosy crimson; Madame Boll (H.P.), very fine habit; Mademoiselle Bonnaire (H.P.), sweetly pretty, nearly white; Triomphe de Lyon (H.P.), splendid dark Rose, but, like a good many of its class, will doubtless fade soon in hot suns.

The second prize was awarded to Mr. W. Paul, of Waltham Cross, for Anna de Diesbach (H.P.), very large, almost like a pæony; Victor Emmanuel, very fine Bourbon; Belle de Bourges-Reine, a very beautiful rose-coloured flower; Anna Alexiell (H.P.), rough; Adolphe Boussange (H.P.), fine purplish-crimson; Homer, fine Tea; Orillanne de St. Louis (H.P.), dark but thin; Buffon (H.P.). I have not entered into lengthened descriptions of these Roses, as I have been blooming them all under my own eye, and shall hope to give, as far as I can, their characters, &c., in some future Number.

CUT ROSES were exhibited in considerable numbers, both from Messrs. Paul & Son and Mr. W. Paul. They were, of course, from plants bloomed under protection, and consisted of the usual effective sorts for such a purpose, and did not present anything worthy of observation. Amongst amateurs, the first prize for Ten Roses in Pots was taken by Mr. Terry, gardener to C. W. G. Puller, Esq., Youngsbury; second, by Mr. Rowland.

The PELARGONIUMS, as usual in June, were magnificent; and both amateurs and nurserymen showed to what a point good cultivation and care will bring plants. The contest in the Amateurs' class of large Pelargoniums was an exceedingly close one, there being some difficulty in determining which were the most effective. Mr. Nye, of Clewer, and Mr. Bailey, of Shardeloes, running very closely, the former winning the first prize by a neck. His plants were—Carlos, Fairest of the Fair, Sir Colin Campbell, Viola, Saracen, Empress Eugénie, Flora, Sanspareil, Rose Celestial. The second contained Gem of the West, King of Scarlets, Saracen, Bianca (the frail one was the weak point in the lot, and decided the race, not being so fully bloomed), Spotted Gem, Eugène Duval, Mr. Marnock, Sanspareil, Carlos. Mr. Shrimpton, gardener to A. F. Doxat, Esq., Putney Heath, was third; and Mr. J. Weir, The Elms, Hampstead, fourth.

Amongst Nurserymen in the same class Mr. Charles Turner, of Slough, was, as usual, first with Candidate, Sir Colin Campbell, Nestor, Sanspareil, Desdemona, Festuc, Viola, Governor General, Rose Celestial, Ariel, Prince of Wales, and Fairest of the Fair. Messrs. Dobson & Son were second; and Messrs. Fraser & Son, of Lea Bridge Road, third.

In FANCY PELARGONIUMS, the first prize amongst Amateurs was obtained by Mr. Bailey, of Shardeloes, with fine plants of Lady of the Lake, Princess Royal, Formosissima, Attraction, Acme, and Evening Star.

Amongst Nurserymen, Mr. Charles Turner held his well-earned place with wonderful plants of Cloth of Silver, Acme, Musjid, Celestial (a beautiful plant, completely covered with bloom), Lady Craven, Rosabella, Captivation, Circle, and Modestum. Nothing could exceed the cultivation of this group.

Messrs. Fraser, of Lea Bridge Road, were second with a well-grown group.

In Nine Spotted Varieties there was, not any competition;

the only group exhibited being one by Mr. Charles Turner, with Bertie, Mr. Marnock, Conspicua, Osiris (very dark), Guillaume Sevryns, Madame Furtado, Beadsman, Picnic, and Peacock.

Several promising Seedlings, of which I dare say we shall see more by-and-by, were contributed by Messrs. Turner, Beck, and Dobson. Amongst those of the former were also some from that eminent raiser, Mr. Hoyle, of Reading. By-the-by, it is no slight tribute to the excellence of his flowers, that, although Mr. Foster, of Clewer, has been an equally large raiser, yet in his own group exhibited to-day all the flowers but two were either Turner's or Hoyle's. There is such a muddle always in the seedlings that one can with difficulty see what are really exhibited. Turner's Diaphantus (racehorses and actresses seem special favourites amongst raisers) is a beautiful soft rose, but apt to burn at the end of the spot. Hoyle's Mrs. Hoyle, a fine soft purple, with white throat; Beck's Butterfly, a very dark spot—the French varieties, in fact, are now assuming the shape of the English fancy; Beck's Peeress (a fine dark flower), Turner's John Leach (a most beautifully-shaped spotted variety, and as smooth as possible), Dobson's Mademoiselle Patti (a fancy variety of lively colour), were amongst some of the most noticeable; but on some future occasion, when it can be done with less hurry, I shall be able to speak more at length on these novelties.

Several stands of PANSIES were exhibited, both in florists' varieties and, in what will ultimately, I see, be a favourite class—the Belgian or fancy varieties. I wish that those good people, who talk about the conventionalities of florists, and say that flowers are drawn more perfect than they really are, would take the trouble to look at a good stand, such as that exhibited by Messrs. Downie & Laird. There was one, Lady Lucy Dundas, which was as completely circular as if a crown piece had been laid down and the outline of the flower cut to it. Having mentioned this box I may say that it contained Seraph, Lord Clyde, Imperial Prince, Countess of Rosslyn, Duchess of Wellington, Rev. H. H. Dombain, Mrs. Hope, Nepaulese Chief, Una, C. W. R. Ramsay, Ladyburn Beauty, Royal Standard, General Young, Miss Carnegie, Nymph, Cherub, Miss Talbot, Lady Belhaven, Rev. Joshua Dix, Mary Lamb, Perfection, Mrs. Laird, Reine Blanche, Mr. Graham, Mrs. Laing, Rev. J. White, Dr. Stewart, Saturn, Midnight, Lady Lucy Dundas, Yellow Beauty, Alexander McNab, Isa Craig, Jessie, Mrs. Downie, and Captain B. Stewart. Other boxes were contributed by Messrs. Shenton and Bragg. Some of the fancy varieties were very curious, and there was really an approach, both in shape and substance, to many of the florists' kinds.

A fine stand of VERBENAS was also contributed by Mr. Chas. Turner, of Slough, to which fourth prize was appended, confusing everybody, as there were none others. It contained Firefly (very bright scarlet), Bellona, Angelina, Elfrida, Minnie, Garibaldi (said to be the best Verbena out, but certainly, as shown here, deficient as a trusser), Souvenir de Victoire Modeste, Admiral Dundas, Diadem, Miss Ivory, General Simpson, Mr. Foster, Premier, Venus, Comet, Rose Imperial, Matilde, Hankye, Miss Dolby, Toratore, Seedling Pink, Magnificens, Prince Frederick, and The Pride.

Amongst miscellaneous objects bearing on my peculiar line were the hardy Rhododendrons exhibited by Messrs. Noble and Mr. Standish, who each sent some promising seedlings; one by the latter, called Climax, of a rich purplish-crimson, spotted, with fine foliage, was very remarkable. Messrs. Veitch and Son also contributed a Mimulus, called cupreus, from Chili, which they have proved to be perfectly hardy. It is a bright orange of very dwarf growth. Mr. Standish also exhibited Azalea anæma hybrida, a small, neat, and hardy sort. Calceolarias, both shrubby and herbaceous were exhibited, but Mr. Burley's fine plants were badly placed for seeing. There was also a nice new bedding kind called Canary, and another already noticed—angustifolia globosa.

No one can have any idea what an amount of labour and anxiety this Show must have occasioned to all concerned; and, notwithstanding all Mr. Eyles' well-known experience, this must have taxed him to the uttermost; and the manner in which he met the wishes of the exhibitors, his urbanity and good temper, were beyond all praise. Doubtless another year will suggest some alterations. It seems too bad to carp where all was so well done; but I do hope the florists will be more encouraged next year at the first Show. In all else they are liberally dealt with. A few prizes, even of small amount, distributed amongst them, would doubtless bring together a.

large amount of contributions. It showed some energy and interest in growers that, despite of this, so many things were contributed. May their zeal meet its reward.—D., Deal.

THE PRIZE LIST.

FLOWERS.

Class 1.—FIFTEEN STOVE AND GREENHOUSE PLANTS (Open).—First, W. May, gardener to J. Spode, Esq., Rugeley. Second, B. Peed, gardener to J. Tredwell, Esq., Lower Norwood.

Class 2.—TWELVE STOVE AND GREENHOUSE PLANTS (Nurserymen).—First, J. Veitch & Son, Exeter and Chelsea. Second, W. Cutbush, jun., Barnet. Third, O. Rhodes, Sydenham.

Class 3.—NINE STOVE AND GREENHOUSE PLANTS (Amateurs).—First, H. Chilman, gardener to Mrs. Smith, Ashted. Second, J. Green, gardener to Sir E. Antrobus, Lower Cheam. Third, J. Baxindine, gardener to W. H. Smallpiece, Esq., Guildford. Fourth, W. Kaile, gardener to the Earl of Lovelace, Ripley.

Class 4.—SIX STOVE AND GREENHOUSE PLANTS (Amateurs).—First, T. Page, gardener to W. Leaf, Esq., Streatham. Second, J. Tegg, gardener to Baron Hambro', R. champton.

Class 5.—TWELVE FINE-FOLIAGED AND VARIEGATED PLANTS (Nurserymen).—First, J. Veitch & Son, Exeter and Chelsea. Second, B. S. Williams, Holloway. Third, T. Jackson & Son, Kingston. Fourth, J. & C. Lee, Hammer-smith.

Class 6.—TEN FINE-FOLIAGED AND VARIEGATED PLANTS (Amateurs).—First, H. Hamilton, gardener to T. Butt, Esq., Cheltenham. Second, A. H. Gunner, gardener to W. F. Wooller, Esq., Kensington. Third, C. Hutt, gardener to Miss Burdett Coutts, Highgate. Fourth, G. Young, gardener to W. H. Stone, Esq., Dulwich. Extra Prize, G. Nicholson, Bushy Grove, Watford.

Class 7.—SIX DRACENAS AND CORDYLINES (Open).—First, J. Veitch and Son, Exeter and Chelsea. Second, J. & C. Lee, Hammersmith. Third, W. Bull, Chelsea. Fourth, G. Young, gardener to W. H. Stone, Esq., Dulwich.

Class 8.—TWENTY ORCHIDS (Amateurs).—First, B. Stone, Tottenham. Second, B. Peed, gardener to J. Tredwell, Esq., Lower Norwood.

Class 9.—SIXTEEN ORCHIDS (Nurserymen).—First, J. Veitch & Son, Exeter and Chelsea. Second, S. Woolley, Cheshunt. Special Prize, O. Rhodes, Sydenham.

Class 10.—TEN ORCHIDS (Amateurs).—First, G. Baker, gardener to A. Bassett, Esq., Stamford Hill. Second, F. Lovell, gardener to H. E. Garney, Esq., Natfield. Third, C. Penny, gardener to H. H. Gibbs, Esq., Regent's Park. Fourth, E. McMorland, gardener to J. Spode, Esq., Hampstead.

Class 11.—ORCHIDS, Single Specimens (Open).—First, R. Warner, Esq., Broomfield. Second, B. S. Williams, Holloway. Third, J. H. Hedge, Ipswich.

Class 12.—NINE GREENHOUSE AZALEAS (Amateurs).—First, T. Page, gardener to W. Leaf, Esq., Streatham. Second, S. M. Carson, Chem. Third, J. Green, gardener to Sir E. Antrobus, Lower Cheam. Fourth, B. Peed, gardener to J. Tredwell, Esq., Lower Norwood.

Class 13.—NINE GREENHOUSE AZALEAS (Nurserymen).—First, C. Turner, Slough. Second, J. & J. Fraser, Lea Bridge Road.

Class 14.—SIX GREENHOUSE AZALEAS (Amateurs).—Prize, W. May, gardener to J. Spode, Esq., Rugeley.

Class 15.—NINE GREENHOUSE AZALEAS, New Kind (Open).—First, C. Turner, Royal Nursery, Slough. Second, Ivory & Son, Nurserymen, Dorking.

Class 16.—SIX RHODODENDRONS, Distinct (Open).—First, C. Noble, Sunning Dale, Bagshot. Second, J. Standish, Bagshot, Surrey.

Class 17.—RHODODENDRONS, Sikkim and Bhotan (Open).—Prize, A. Henderson & Co., Edgeware Road.

Class 18.—FIFTEEN ROSES IN POTS, Distinct (Open).—First, H. Lane and Son, Great Beckhampstead, Herts. Second, W. Paul, Waltham Cross. Third, E. Francis, Hertford.

Class 19.—TEN ROSES IN POTS, Distinct (Amateurs).—First, T. Terry, gardener to C. W. Giles Puller, Esq., Youngsbury. Second, A. Rowland, Lewisham, Kent.

Class 20.—TWELVE NEW ROSES, in Pots, two of kind admitted (Open).—First, Paul & Son, Cheshunt. Second, W. Paul, Waltham Cross.

Class 21.—SIX TALL CACTI (Open).—First, J. Green, Cheam. Second, W. Young, Highgate.

Class 22.—SIX CAPE HEATHS (Open).—First, B. Peed, gardener to J. Tredwell, Esq., Lower Norwood. Second, T. Jackson, & Son, Kingston, S.W. Third, W. May, gardener to J. Spode, Esq., near Rugeley. Fourth, E. Baxindine, gardener to W. H. Smallpiece, Esq., Guildford. Extra Prize, T. Page, gardener to W. Leaf, Esq., Streatham.

Class 23.—NINE PELARGONIUMS, Distinct (Amateurs).—First, W. Nye, gardener to E. Foster, Esq., Clewer. Second, T. Bailey, Amersham. Third, J. Shrimpton, gardener to A. F. Daxat, Esq., Putney Heath. Fourth, J. Weir, Hampstead.

Class 24.—TWELVE PELARGONIUMS, Distinct (Nurserymen).—First, C. Turner, Royal Nurseries, Slough. Second, Dobson & Sons, Isleworth. Third, J. & J. Fraser, Lea Bridge Road. Fourth, T. Windsor, Nurseryman, Hampstead. Extra Prize, J. Burley, Limsfield.

Class 25.—SIX FANCY PELARGONIUMS, Distinct (Amateurs).—First, T. Bailey, Amersham. Second, J. Weir, Hampstead. Third, J. James, gardener to F. W. Watson, Esq., Isleworth.

Class 26.—NINE FANCY PELARGONIUMS, Distinct (Nurserymen).—First, C. Turner, Royal Nurseries, Slough. Second, J. & J. Fraser, Lea Bridge Road. Third, Dobson & Sons, Isleworth. Fourth, T. Windsor, Hampstead.

Class 27.—NINE SPOTTED PELARGONIUMS, Distinct (Open).—Prize, C. Turner, Royal Nurseries, Slough.

Class 28.—NINE VARIEGATED BEGONIAS, Distinct (Open).—First, J. Veitch and Son, Exeter and Chelsea. Second, W. Lakeman, Hendon. Third, A. Henderson & Co., Edgeware Road. Fourth, B. S. Williams, Holloway.

Class 29.—SIX TREE FERNS, Duplicates admitted. (Open).—First, J. Veitch and Son, Exeter and Chelsea. Second, C. Hutt, gardener to Miss Bardett Coutts, Highgate. Third, J. Standish, Bagshot.

Class 30.—TWELVE EXOTIC FERNS (Amateurs).—First, J. Stone, Tottenham. Second, R. Baillie, Harrow Road. Third, H. Lavey, Fetcham, Surrey. Fourth, S. M. Carson, Cheam.

Class 31.—TWELVE EXOTIC FERNS (Nurserymen).—First, B. S. Williams, Holloway. Second, J. Veitch & Son, Exeter and Chelsea. Third, R. Sim, Foot's Cray. Fourth, Milne & Co., Wandsworth Road.

Class 32.—SIX ANGIOCHILUS AND VARIEGATED-LEAVED ORCHIDS (Open).—Prize, J. Veitch & Son, Exeter and Chelsea.

Class 33.—THREE TUBEROUS TROPEOLIMS, trained. Distinct. (Open).—No competition.

Class 34.—NEW OR EXTREMELY RARE PLANTS IN FLOWER.—First, R. Warner (Laelia grandis) S.K. Second, J. Pibean (Dendrobium sp.) S.B. Second, J. Veitch & Son (Stenogaster concinna) S.B. Second, M. Lindén, Brussels (Camp. lobortus pyrophylla) S.B. Third, E. & G. Henderson (Convolvulus mauritanicus) M. Third, J. Veitch & Son (Mimulus cupreus, M. and Calceolaria bellidifolia, M.)

Class 35.—HARDY ORNAMENTAL PLANTS.—First, J. Standish (Sciadopitys verticillata) S.K. First, J. Veitch & Son (Libocedrus tetragonus) S.K. Second, J. Standish (Retinospora obtusa, S.B., and Thujaopsis dolabrata, S.B.) Second, J. Veitch & Son (Acer polymorphum atropurpureum) S.B. Third, J. Veitch & Son (Thuja pygmaea, M., and Cryptomeria sp., Japan) M. Third, J. Jackson & Son (Juniperus drupacea) M. Third, J. Standish (Retinospora obtusa, var. M., Podocarpus variegatus, M., Aucuba japonica, M., and Bambusa variegata, M. Third, J. Veitch & Son (Ficus sp.) (Vancouver's Island) M.

Class 36.—WARDIAN CASES FILLED WITH PLANTS.—First, J. Veitch and Son, Exeter and Chelsea. Second, J. Standish, Bagshot. Third, R. Baillie, gardener to W. C. Carbonell, Esq., Harrow Road.

Class 37.—MISCELLANEOUS (for Plants not specially named).—First, J. Veitch & Son, Exeter and Chelsea. First, Carl Petersdor, Kensal New Town. Second, J. Standish, Bagshot. Second, W. Paul, Waltham Cross. Second, H. Lavey, gardener to E. A. de Grave, Esq., Fetcham, Surrey. Second, J. Standish, Bagshot. Second, J. Veitch & Son, Exeter and Chelsea. Four Seconds, M. Lindén, Brussels. Third, M. Lindén, Brussels. Third, B. S. Williams, Holloway. Third, R. Baillie, gardener to W. C. Carbonell, Esq., Harrow Road. Fourth, J. Burley, Limsfield, Surrey. Fourth, C. Turner, Slough. Extra Prize, J. Standish, Bagshot; Paul & Son, Cheshunt; Dobson & Son, Isleworth; Ivory & Son, Dorking; C. Leach, Clapham Park; B. S. Williams, Holloway; T. Baines, Cheshire.

FRUITS.

Class A.—COLLECTION OF FRUIT (nine dishes of six distinct kinds).—First, T. Ingram, Royal Gardens, Windsor. Second, A. Henderson, Tientham.

Class B.—PINE APPLE (the best Queen).—First, T. Bailey, Amersham. Second, T. Young, gardener to C. Bailey, Esq. Third, R. Ruffett, Brocket Hall, Herts.

Class C.—PINE APPLE (the best Cayenne).—First, T. Page, Streatham. Second, T. Ingram, Frogmore. Third, C. F. Harrison, Weybridge.

Class D.—PINE APPLE (any variety, not Queen or Cayenne).—First, T. Young, gardener to C. Bailey, Esq. Second, R. Ruffett, Brocket Hall, Herts. Third, T. Bailey, Amersham.

Class E.—GRAPES, Black (Single dish).—First, W. Hill, Keele Hall, Stafford. Second, C. Little, gardener to A. Darley, Esq., Slough; J. Fleming, Clevedon. Third, J. Drevitt, gardener to Mrs. Cabitt, Dorking; G. G. Wortley, gardener to the Hon. P. Carey, Norwood; M. Henderson, Ashby-de-la-Zouch. Extra Prize, H. Payne, Cheshford; G. Tillyard, Stanmore; T. Frost, Aylesford.

Class F.—GRAPES, White Muscat (Single dish).—First, H. Baker, Leicester. Second, R. Ruffett, Brocket Hall, Herts. Third, J. Standish, Bagshot. Fourth, R. Turnbull, Woodstock.

Class G.—GRAPES, White, not Muscat, (Single dish).—First, W. Hill, Keele Hall, Stafford. Second, J. Allport, Nantwich. Third, F. W. Durrant, St. Neot's; J. Cross, Leicester. Extra Prize, T. Bailey, Amersham.

Class H.—PEACHES (Single dish).—First, A. Henderson, Trentham. Second, A. Sanders, gardener to Sir H. Meux, Theobalds; J. Fleming, Clevedon. Third, C. Little, gardener to A. Darley, Esq., Slough; F. W. Durrant, St. Neot's. Extra Prize, J. Peacock, Luton; J. Cross, Airedale.

Class I.—NECTARINES (Single dish).—First, M. Rochford, Tottenham. Second, J. Peacock, Luton. Second, A. Henderson, Trentham. Third, W. Hill, Keele Hall, Stafford. Third, S. Evans, Nuneaton. Extra Prize, J. Gates, Stoneleigh Abbey; C. Little, gardener to A. Darley, Esq., Slough; T. Rawbone, Stone, Stafford.

Class J.—FIGS (Single dish).—First, J. Cross, Airedale. Second, S. Snow Silsoe, Beds. Third, R. Ruffett, Brocket Hall, Herts.

Class K.—CHERRIES (Single dish).—First, A. Henderson, Trentham. Second, S. Evans, Nuneaton. Third, T. Jackson & Son, Kingston.

Class L.—STRAWBERRIES (Three dishes, distinct).—First, R. Smith, Twickenham. Second, R. Turnbull, Blenheim. Third, F. W. Park, Grove Hall, Notts. Extra Prize, A. Ingram, gardener to J. J. Blandy, Esq., Reading.

Class M.—STRAWBERRIES (Single dish).—First, R. Smith, Twickenham. Second, T. Ingram, Frogmore. Third, F. W. Park, Grove Hall, Notts.

Class N.—STRAWBERRIES IN POTS (Six plants).—First, R. Smith, Twickenham. Second, W. Kaile, gardener to Earl Lovelace, Ripley. Extra Prize, T. Reid, Sydenham.

Class O.—MELONS, Green-fleshed.—First, J. Meredith, Garston, near Liverpool. Second, T. Frost, Preston Hall, Kent. Third, Rev. T. Phillipot, Turo. Extra Prize, A. Sanders, gardener to Sir H. Meux, Theobalds; W. McLellan, Barnet.

Class P.—MELONS, Scarlet-fleshed.—First, T. Frost, Preston Hall, Kent. Second, T. Kempster, gardener to Edward Greaves, Esq., Barford, Warwick. Third, J. Meredith, Garston, near Liverpool.

Class Q.—VINES in pots (Four Plants).—First, A. Sanders, gardener to Sir A. Meux, Theobalds. Second, G. Masters, gardener to the Earl of Maccles-

field, Tetsworth. Third, J. Standish, Bagshot; C. Hutt, gardener to Miss Burdett Coutts, Highgate.

Class E.—MISCELLANEOUS.—Prize, J. Standish, Bagshot (Grapes). Prize, J. Standish (Jingam's Prolific Grape). Prize, J. Luscombe, Kingsbridge (Oranges and Lemons). Prize, T. Lunt, Greenock (Apricots). Prize, H. Payne, Chelmsford (Black Hamburgh Grapes). Prize, J. Henderson, Trentham (Trentham Black Grapes). Prize, W. Kaile, Ripley (Muscat Citronelle Grapes). Prize, R. Crawshaw, Meithyr Tydvil (Bananas).

SPECIAL PRIZES OFFERED BY C. W. DILKE, ESQ., V.P.R.H.S.—First, T. C. March, Lord Chamberlain's Office. Second, Lady Rokby, Montague House. Third, Lady Caroline Kerrison, 140, Piccadilly. Fourth, Elkington and Mason, 21 and 22, Regent Street. Highly Commended, Lady Trowbridge, 8, Prince's Gate.

KIDDEAN MODE OF HEATING.

At page 99 of No. 6, a correspondent describes his application of this mode of heating to a small greenhouse. In answer to our request for further information he writes as follows:—

GROUND PLAN OF GREENHOUSE.

- No. 1.
A Stokehole.
B Flagstone, forming the top of the air-chamber.
C Openings from the chamber for the hot air to enter the house.
D Flue and chimney.

GROUND PLAN OF STOKEHOLE AND FURNACE. FRONT ELEVATION OF FURNACE.

No. 2.

No. 3.

- A Stokehole.
B Ash-pit.
C Air-chamber.
D Openings to admit cold air into the chamber. These might be fitted with sliding-doors, and so regulate the supply of hot air to the greenhouse.
- A Iron plate forming the top of the furnace.
B Furnace door.
C Ash-pit.
D Openings for the cold air to enter the chamber.
E Showing how the hot-air chamber surrounds the furnace; the dotted lines being the furnace sides.

"No. 1 is the house showing the partition. No. 2, the ground plan of the furnace, air-chamber, &c., and No. 3 is the front elevation of the furnace and chamber: Of course any one else who applied this system of heating would have the fireplace outside, and in a larger house it would be as well to have only a small opening as at c1, in plan No. 1, and from c2, to carry a flue of drain tiles to the other end of the house. The hot air would then be more equally distributed. In a larger furnace than mine both the top of that and of the chamber should be arched, though, with a furnace of brick altogether, the heat could not be got up so rapidly as an iron top would do it. I hardly know what fuller details to give you. The only explanation I ever had of the Kiddean system, was that in your Number of the 29th of January. The whole affair seems so simple, that I cannot make out how any one can well help understanding it.

"What do you think of the following mode of striking cuttings? I have been most successful with it. Crock the pot quite one-

third full; put a large piece at the top of the crockery, so as to prevent the earth getting amongst the drainage; then an inch or two of very rich leaf mould; lastly, a thick layer of silver sand. Put the cuttings in the sand, and give a moderate watering. Stand the pot in a saucer large enough to take a bell-glass that will cover the pot, and leave 2 inches or 3 inches space above the pot. Now pour an inch or so of water into the saucer, and your cuttings will not want even looking at until all are struck. The only precaution necessary is to see that the pot is crocked above where the water in the saucer reaches. There is no evaporation from the cuttings—they never flag, and, from my experience, I should say never miss rooting. Mind, I am not recommending this to those who can have frames and bottom heat and all sorts of appliances, and who can be always looking after their plants; but to those who, like myself, have sometimes to leave their plants to take care of themselves for a day or two; because, after the cuttings are once in, they require no attention until they are fit to pot off.—W. A."

[We have no doubt that the plan of the stove will answer well, and are much obliged for the plans and descriptions sent, which will, we doubt not, be useful to many. We begin to doubt of the great economy for large houses, if drains, &c., must be used for regulating the heat. For real economy in moderate-sized places, nothing yet seems more economical than brick stoves as used by Mr. Rivers, and lately described by Mr. Fish. He does a great deal of work with them, without the necessity of an air-chamber at all.

Your plan of propagating is good for softwooded plants; but we would do without the leaf mould above the drainage. Many cuttings would get miffy on reaching it.]

POLMAISE SYSTEM OF HEATING.

YOUR correspondent "E. H." says he believes that the usual objections to Polmaise are—"1. Waste of fuel. 2. Burning the air by the excessively hot surface required. 3. Splitting the furnace."

I have used Polmaise regularly for ten or twelve years, and have experienced none of these bad effects. My two stores, made of wrought iron, have never required any repairs, except fresh firebricks, and are, I believe, as good as when they were put up. The consumption of fuel is very small; and as regards "burning the air," I consider it very bad practice in Polmaise to have a very hot surface.

But though I differ with your correspondent on these points, I quite agree with him that long flues, or air-drains, are unnecessary. In Polmaise nothing is needed but a drain close by the stove going down to the bottom of the hot-air chamber, and an outlet at the top of the chamber to admit the hot air into the house.—W. C.

HOW TO SHARPEN LAWN-MOWING MACHINES.

I HAD occasion to visit Macclesfield a few days ago, and, as usual, took a stroll into the beautiful public park there. The intelligent curator, Mr. Middlebrook, received me very kindly, and walked round with me. Every part of this People's Park was in excellent order, and I was very glad to find the shrubs had not suffered so much from the severity of the past winter as they have done in many localities in the neighbourhood. This exception may be accounted for by the fact of the soil being of a poor, sandy nature on a gravelly subsoil, and the elevated table-like character of the land. Common Laurels, indeed, with few exceptions, were killed down to the ground, and also *Laurustinus* and *Aucubas*; but Portugal Laurels were only a little touched, and most of the Coniferous tribe had escaped. I was particularly struck with the beauty and hardihood of the *Pinus austriaca*, it being as green as possible, and not a leaf injured. Even the young shoots had not suffered by the smart frost of the night of the 12th of May last. This beautiful tree is truly desirable, and I find it thrives best of any of the tribe near large, smoky towns. I can recommend it to every one about to plant. The common Scotch Fir is certainly not so hardy as this species. As a shelterer to tenderer kinds I know no tree equal to it.

The part of the park used as a bowling-green was almost as smooth as a planed board, and in conversation with Mr. Middlebrook, he expressed his surprise that none of the writers of THE

JOURNAL OF HORTICULTURE had ever given instructions how to sharpen mowing machines. I replied that in my case at least, not having written the instructions was because I did not know how to sharpen the machines. No doubt, I remarked, many gardeners would be glad to have instructions on that point; and if he would tell me how to do it I would write down his instructions and send them to the office. Forthwith he had a machine brought out and showed me how he performed the operation. I took down his remarks, and now copy them out for the benefit of our readers.

Previously, however, to going into the subject, I would remark that many a gardener has given up the use of these machines on account of not knowing how to sharpen them. "Give me my scythe again," he said, "I can sharpen it by whetting; but when this machine gets out of order I have to send it to a machinist to sharpen and put to rights, and even then it is soon out of order again, so I think the scythe after all is the best tool for lawn cutting." This I am sure is a great mistake, and I trust I shall make the sharpening of this useful instrument, the lawn-cutting machine, as easy to manage as whetting a scythe.

To proceed, then. Place the machine handle under the lower bar of a fixed hurdle or under a pair of stakes placed crosswise thus X. When in that position the cutting parts will, of course, be swung clear off the ground. Then take off the one wheel from the side where there is a hole to receive a handle, fasten that handle in, unscrew the top screws, and screw up the bottom screws just enough to admit a flat piece of iron with a handle made expressly for this purpose (see cut). Thrust this flat iron

The machines vary in width, so the length must be the same as that of the spiral knives. Thickness of the iron about the same as a halfpenny, brought to an edge in front.

between the spiral knives and the flat knife below them. Apply to it a mixture of superfine emery (no other kind will do) and sweet oil; then screw down the spiral knives pretty tight to it, and with the handle turn them the contrary way to that which they turn when cutting the grass. Continue the turning until an even sharp edge is produced on all the spiral knives—an operation that will not take more than five minutes unless the knives are very much out of order. This sharpening should be done frequently. Mr. Middlebrook said, supposing the machine is used every day, it would need sharpening once a week.

The use of the flat piece of iron is to preserve the lower flat knife or blade which the sharpening process would soon wear away.

Sometimes a stone, or, may be, more, get in between the knives and cause an indentation, or, as machinists term it, a buckle, on the flat knife. To remedy this, pack sufficient thick brown paper under it, and screw it up till the indent or buckle is even with the rest of the blade. This packing will keep it right till a fresh stone gets in, but with care and constant rolling such misfortunes will be avoided.

Such were the instructions my friend gave me. Let any gardener that has mowing machines that require sharpening try the plan. He may not succeed the first time, but let him try again, and by perseverance he will succeed. It is difficult by description to tell how to perform any operation. If I was to describe, for instance, the operation of whetting the scythe, even that, simple as it seems to an old hand, would require long practice before the tyro would become an expert whetter.—T. APPELEY.

A GLASS HOUSE FOR MANY PURPOSES.

I WANT to grow Cucumbers; I want to preserve a few plants in winter—principally bedding-out plants, and, if required, I want to be able to raise a few seeds which require heat. I am willing to do without the last if it is impracticable; but I should like to combine the first two wants. I do not want to go to a very great expense, nor would it be wise to do so even if I could afford, as we schoolmasters are often "here to-day and gone

to-morrow;" but I certainly do aspire to a flued pit or very small house. Whatever it be, I should like it to contain about 100 square feet superficial. The situation it would occupy backed by a Privet and Thorn-hedge. If the house was moveable, and at the same time durable, I should prefer it. Will you kindly advise me as to which will be the better—a pit or frame, or a small house, the best means combined with cheapness of heating it, the best plan of building it, and anything else you may think it best for me to know?—A COUNTRY SCHOOLMASTER.

[We hardly know how to advise you to meet your various wants, and more especially as the house must be small to contain not more than 100 square feet. Instead of having a square house, however, it would be better to have one 13 feet by 8 feet, or 15 feet by 7 feet, or even 17½ feet by 6 feet or 6½ feet. We would decidedly recommend a little house in preference to a pit or frame, so far as feeling an interest in the necessary minutiae are concerned. A small pit, say 3½ feet high at back, and 2½ feet at front, and some 5½ feet wide, and 18 feet long, would be the easiest managed perhaps, as you could cover in severe weather; but then you could not get among your plants nicely in such weather. Again, a span-roofed house, or half-span would cost less for walls than a lean-to; but more for glass, and rather more for heating. Then the heating is another bore: a small brick or Arnett's iron stove, of the simplest kind, would keep all bedding plants safe with a little care; but it could not be depended on for Cucumbers at all early. Again, your combination of bedding plants and Cucumbers must proceed on the understanding that established plants of both must not be in the same house at the same time; so that you could not expect to obtain early Cucumbers, and yet keep a healthy stock of bedding plants in the same place: a compromise, therefore, must be made. A little fire heat is of importance for keeping all bedding plants over the winter. A little extra heat would also be useful in raising cuttings in spring, as well as flower-seeds requiring heat; but these should be removed or hardened off before getting drawn up weak. If, therefore, you had a shallow earth pit, a foot deep, or rather the sides raised with earth 12 inches or 15 inches above the ground level, and a turf placed along the top, and had it, say 4½ feet to 5 feet wide, and from 12 feet to 15 feet long, there you could place all the hardier bedding plants, after being well exposed to air, about the end of March or the beginning of April, and protect them with a piece of strong calico, fastened at each end to a wooden roller, to roll the calico on when removing the cloth. Heat could then be given to suit Cucumbers, and to strike young cuttings and raise seeds; and the Cucumbers could be continued until the middle of October, when they would be cleared out, and the place cleaned ready for the bedding plants, which would have been struck out of doors, as in the scarlet Geraniums, or hand-lights, as the Verbena, or rooted at once in small pots when growing in beds, as layers. If you will turn to page 177, you will perceive three modes, in addition to plans of pits previously given, by which you might carry out your plan, substituting a flue or other means for hot water.

Of these, all things considered, *fig. 40* would, perhaps, be most suitable—say 6 feet from the hedge, 6 feet wide, 18 feet long, 8½ feet high at back, and 2 feet 9 inches in front. The pathway at back would be 27 inches, the bed, stage, &c., in front, would be 3 feet 9 inches, and three or four shelves could be fastened from the back wall, and one or two suspended from the roof, to be used in winter, the door being at one end close to the back wall. Now the furnace for such a house might be at the back between the hedge and the wall; but we certainly should prefer having it inside in imitation of the plan of a correspondent the other week. After getting away

a couple of yards from the fire strong drain-tiles would do as well as anything for a flue, and they would give out enough of heat. For such a house we are convinced that a brick stove placed inside against the back wall would give heat enough in winter, and with a large evaporating-dish on the top of it would give heat enough for Cucumbers in summer; but it would not be so nice for propagating and raising seeds, unless another vessel was made to be suspended over the evaporating-basin, which would answer well so far as its size went. Of course, a flue or hot water in front would be a more tangible affair. It would be as well to agree with the landlord, to avoid all bother about foundations;

but were I resolved to gratify myself, and run no risks, I would have as much as possible of the whole affair moveable to do what I liked with it, or take it where I liked. But for this I would have a fixed roof with moderate-sized sash-bars; but for convenience of moving, though much enhancing the price, I would have the roof in four moveable sashes. We should thus proceed, then, to be independent of everybody, and not even make hardly a hole in the earth. For foundation we would have six blocks of wood 3 feet long and 5 inches square, and these we would imbed in the earth. On these we would screw our sills, 4 inches square; and on them we would mortice and pin with wooden pins the upright studs, to be surmounted with a wall-plate in a similar way for receiving rafters back and front. The back and front wall we would cover with inch-boards, either screwed separately or made into pieces to take down more easily. Width might be allowed to have the inside straight if desirable, and the outside of the studs or the outside of the boards might be covered with asphalt, and the pieces marked so as also to come off easily. A small iron stove in the centre of such a house with an evaporating-pan on the top of it, would keep all bedding plants with common care. Where more was wanted, we would have a small iron stove placed a yard from the end of the house inside, as low as could well be made, and we would also take the earth out there 2 feet or so, even though we must leave it as we found it. To give the stove more room and keep it further from the wood, we would give the stove a space of 6 feet, and put a division there, with a small door to feed it, and at the top of the stove we would have the smallest of Mr. Rivers' boilers, and have two three-inch pipes from it as flow, and one as return nearly on the same level. Any thing could be grown in such a house. Of course, if the hole could be made outside and the little fire fed from the outside all the better; but then it would not be so handy in all weathers. I think for many such little purposes a small moveable furnace and boiler cast together would be very useful, and commend it to Mr. Hughes, of Bishop Stortford, who made Mr. Rivers' small boilers for his brick stoves. If the fireplace of an iron stove is lined with brick, and the fireplace is 2 inches or 3 inches from the iron sides, and the top was a vessel of water instead of mere iron, a small fire and small concern altogether would do for such little places; one great charm of which would then be, that no stoveholes would require to be dug out, nor bricks buried in them, nor drains made to keep them dry, but furnace, boiler, pipes, walls, glass, and altogether, might be packed in a good-sized cart any day and set down where wanted.

I forgot to say that all the joints of the pipes from such a boiler would do well if made with Portland cement, and a little charcoal heat put round them will cause the cement to crack, when it is desirable to take them to pieces. The sashes might be made to move for air; but if the walls were of wood, we should prefer a few shutters made to open or slide—say three, 15 inches by 8 inches at the top of the back wall, and the same number in the front. For flues, &c., full information was given in late Numbers. If when you settle on the plan to be followed and we can further help you, we shall be glad.—R. F.]

ORCHARD-HOUSE AND VINERY MANAGEMENT.

SEVEN years since, from reading Mr. Rivers' work on orchard-houses, I decided on putting up one; and thought the wisest plan was to pay Mr. Rivers a visit, and gain all the information I could before commencing. Mr. Rivers kindly showed me over his houses, and gave me all the information I required. I then proceeded on his plan, and built one 55 feet long by 12 feet wide, 8 feet high at the back, 4 feet high in front, with glass lights in front within 1 foot of the ground, hung on pivots, all to open; a wall at the back, against which I planted three trees, and three in front on trellises in a half-circle, that the trees in front might not shade those on the wall. Two were large trees in a bearing state, and, being carefully removed, bore well the first season. The ventilation is from a door at each end, and three openings of 2 feet square at the top of the wall, but from experience since I have found a narrow shutter of 8 inches wide, hung on hinges and raised by a small upright rod of iron, with a hole punched near the bottom to put on a nail driven in the wall, may be raised any height. This shutter to be fixed on the top of the rafters, and the glass left open as far as this covers, the shutter to lap over the glass

about 1 inch to prevent drip. This I have found the best ventilation of any I have adopted. The house is never oppressively hot, as I have found others with only front and end ventilation. As my trees planted on trellis did not shade or fill up all the house, I obtained some in pots.

The year following I built another house, 50 feet in length by 12 feet in width, 10 feet in height at back and 4 feet in front, but boarded at the back instead of having a brick wall. But I do not approve of boarding so well as a wall; as in the spring, when the trees are in blossom, with a cold east wind and frosty nights, your prospect of a crop may be destroyed by a severe frost, which a good wall would effectually keep out. The trees in this house are planted the same as the first—against the boards at back and on a trellis in front, with a good many in pots where room is to be found. The aspect of this house is south-west by west, which I do not consider so good as south or south-east. The soil is also too rich, and I have some difficulty in checking over-luxuriancy and getting them into a good bearing state.

Having given a statement of my houses, I will now proceed to give an account of the produce. The first year a light crop on the large trees. Every year since a full crop on most of the trees, as they have come into a bearing state. On many a much heavier crop than most experienced gardeners would consider safe for the well-doing of the trees, some bearing upwards of one hundred, and fine fruit. Some Noblesse Peaches weighed 11 ozs.

The pot trees have also borne good crops. Last year several had five dozen on, and a beautiful sight they were—all fine fruit; and notwithstanding the heavy crop, the trees were, and are now, very healthy and luxuriant, although confined to a fifteen-inch pot and not allowed to root into the border. This year the same trees have from four dozen to four dozen and a half, as I considered them over-cropped last year. Our crop of Peaches and Nectarines last year from the two houses must have exceeded a thousand, and the prospect is equally good for a similar crop this year.

I generally commence thinning as soon as the fruits are fairly set, as I think they are less likely to drop if properly thinned early. On many trees I must have taken off nine-tenths. This crop on pot trees could, of course, only be brought to perfection by great attention and care, watering frequently with manure water, and a plentiful supply of water every day in hot weather. I would recommend to any one building an orchard-house to plant the trees in the border, and train on trellis in front and on the wall at the back, as a much greater quantity of fruit may be grown by this plan than from pot trees, and at much less labour and attention. Some of my neighbours have failed in growing a crop of fruit from pot trees, and I think from following Mr. Rivers' instructions rather too literally by giving them no water from October to February, which I find will cause the blossom-buds to break very weakly, and the greater part drop off. Another error is turning the trees out of the house in the autumn for the sake of other plants, and leaving them exposed to frost. My trees are in fifteen-inch pots, and never allowed to root into the border. The pots are all plunged up to the rim. In the spring I give them a pretty liberal supply of salt both over the pots and borders, and, judging from the appearance of my trees, consider it very beneficial. Sometimes I apply a little nitrate of soda, which is a very great fertiliser, and causes the foliage to become very dark and luxuriant.

MY VINERY.—Finding it impossible to grow Vines and Peaches successfully in the same house, I soon after erected a vinery 45 feet in length, 10 feet high at back and 4 feet in front, 13 feet in width, length of rafters 15 feet. Having made a good border nearly 2½ feet deep, with good prepared soil of loam, old mortar, a few ashes, and not an atom of real manure, I proceeded to plant my Vines inside the house 1 foot from the glass; being eight Black Hamburgs—one and two-year-old plants raised by myself, one Prolific Sweetwater, one Esperience from Mr. Rivers, and three Royal Muscadine, planted 3 feet 6 inches apart, and trained to a single rod and spurred. The Vines have flourished exceedingly well. Last year was the first season of bearing; and, from looking so well, induced me to go to the expense of heating the house with hot water, which I accomplished the early part of March, 1860. I allowed from nine to ten bunches on each Vine, thinning them severely. Fire heat was only continued during cold and wet weather. The crop ripened well, and was pronounced by good judges to be very fine. Some bunches weighed 3 lbs., and many 2½ lbs.

The Vines are remarkably strong and healthy this season, and are now carrying from twelve to seventeen bunches each, and promise to be heavier than last year. I fear this crop is too heavy for such young Vines; but they are very luxuriant, and the wood is now beginning to ripen. The Grapes will soon begin to colour, and no indication of mildew. The first remark my friends make on entering the house is, "Well, what manure do you use?" "None at all," is my reply. I have not even given them one can of liquid manure this year, as they are sufficiently strong without.

I have merely to add that I have now planted Vines at the back against the wall, which may be partially trained down the rafters between those which come up, where room is found; as I fear they may not be very productive on the wall, from being shaded too much.—W. E. BUTLER, *Lee Court, Petersfield.*

FOREIGN CLIMATES AND PLANTS.

No. 5.

As this journal is more a record of the productions of the earth than of its localities, any attempt at the description of the magnificent scenery of the Corniche road from Nice to Genoa, through which the writer has recently passed, would probably be out of place; a few cursory notes will therefore only be given.

The temperature had continued about the same as at Nice, the average of the thermometer in the shade during the day being 64°, and in the night 55°. At Milan it became considerably cooler; but on the Lake of Como the temperature again increased; and passing onwards from thence by Lugano to Lago Maggiore, great heat has been experienced—in fact, the sun has become too powerful to allow of walking out comfortably in the middle of the day. The thermometer has been at 80° in the shade in the day, and upwards of 60° at night. There has been hardly any rain for the last six weeks, but almost continual clear sunshine, so that the country stands much in need of an early fall.

The Grape Vines appear to shoot vigorously, and the bunches numerous; but in many places there are appearances of the ravages of the oidium in the past year, and sulphur is in course of application. At Lugano the ordinary wine is very inferior, and I was told the Grapes have not been good there during the last ten years.

In the palace gardens of the Prince of Monaco I observed a rather novel application of the Myrtle; it was used for edging to the flower-borders, and kept cut in, as Box is with us. It had a very neat appearance, although it seemed to be rather a degradation of so nice a plant. The sides of the roads and hills are quite gay with the profuse blossoms of the white Acacias, used in many places for hedges, and on the railway embankments. On the Lake of Como the Laburnum was in full flower, and quite wild, presenting a luxuriant appearance on the rocks down to the water's edge. It is also very abundant with the white Guelder Rose (*Viburnum opulus*) on Mont Salvatore at Lugano.

The Camellia trees (as they may be called) attain a large size in the open air by the Lake of Como, especially in the gardens of the villas Sommariva and Melzi; our greenhouse Azaleas also there flourish without protection, and are very fine. Large branches were cut and given by the gardener to visitors, as almost a matter of course; there are also fine trees of the Paulownia imperialis covered with their beautiful purple gloxinia-like blossoms.

The Banksian Roses, both white and yellow, grow in the greatest profusion, and also the Chinese Laburnum (*Wistaria sinensis*) running up to the tops of houses, and amongst the branches of the Cedar and other trees; they have been almost one mass of blossom. In some places the Banksian Roses are shorn as our quick hedges in England, and still flower all over.

For some time past the Alpine Strawberries and Cherries have been placed on the tables for dessert. At Genoa, on the 3rd of May, the garden Strawberries were in the market.

The wild flowers in the fields are in great beauty. One of the most conspicuous is the *Salvia pratensis* or Meadow Clary, which is most abundant, and attains a large size, with long spikes of purple blossoms. Sometimes variegated white and purple, Orchises as well as *Serapias* are very plentiful, and the *Narcissus poeticus* near Lugano. At Milan six bunches of Lilies of the Valley were sold in the streets for a penny. Solomon's Seal (*Convallaria multiflora*) is frequently met with, and on Mont Salvatore, near Lugano, I found the beautiful blue *Gentiana acaulis*, also *Daphne cneorum* in quantity, with the *Polygala*

chamæbuxis, and a handsome variety (lilac and yellow) of the same.

The rarer Ferns which have been met with were *Asplenium Petrarchæ* and *Pteris cretica*, at Nice; the *Asplenium fontanum* plentifully near Mentone, and sparingly at Nice; also at Mentone, *Cheilanthes odora*, and *Gymnogramma leptophylla*; at Roquebrune a fine variety of *Polypodium serratum* (almost equal to *cambricum*) and plenty of the *C. odora*. *Adiantum capillus-Veneris* is met with almost everywhere. At Lugano, the *Cystopteris fragilis*, *Polypodium dryopteris*, *P. phlegopteris*, *P. calcareum*, *Lastrea oreopteris*, *L. femina* and others; and here (*Braveno*) the *Osmunda regalis* grows very large.—E. COPLAND, *Braveno, Lago Maggiore, 27th May.*

VARIEGATED PLANTS.—In my opinion the best collection of hardy ornamental variegated plants that ever has been sent to this country by one man, and at one time, has just arrived from Japan, and are in the possession of Mr. John Standish, of the Royal Nursery, Bagshot. They were procured by Mr. Robert Fortune, the botanical collector. For making improvements in landscape gardening, or planting for artistic effect, they are a valuable acquisition. I think that after the exhibition of the Royal Horticultural Society's Gardens at Kensington Gore, this fine collection should be exhibited at the Floral Hall for two or three days, the public generally would then have an opportunity of appreciating their beauty and novelty. No lover of horticulture could but be delighted with the sight of so many rare and curious specimens. A trip to Bagshot to see that collection only will well repay for the journey.—JOSEPH NEWTON, *Landscape Gardener, 30, Eastbourne Terrace, Hyde Park.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE trenching of vacant ground to be carried on where required; and if manure is wanted on ground about to be planted it is best to lay it on the top after it is trenched, and then to fork it in. Keep all advancing crops in a vigorous growing state by timely applications of water in dry weather, and frequent surface stirring. *Asparagus*, to maintain the strength of the grass next year, no more of the produce should be cut; late and close cutting is one of the principal causes of weak grass. *Cauliflowers*, the plants which are now forming their heads to be watered, and mulched with short litter; this will cause them to come close and compact. *Celery*, continue to plant successional crops into trenches; the plants to be taken up with as much soil around the roots as possible, and on no account to shorten the leaves; a good soaking of water to be given immediately after they are planted. *Dwarf Kidney Beans*, a few more to be sown for succession. *Endive*, make a sowing for the main autumn crop. Plant out a few of the early sowing. *Herbs*, propagate by cuttings. The best time for cutting them for drying will be just as they are coming into flower. *Lettuce*, tie up some for blanching, and make a sowing in drills where they are to remain. *Peas*, keep up the sowing of successional crops, and do not neglect to get in a good breadth of the latest directly in drills soaked with water. No sowing after this can be relied on to produce a crop. *Potatoes*, earth up the main crops after rain; keep the ground between the rows loose. *Spinach*, sow a few rows for succession; water the drills before sowing, and again after covering them. *Scarlet Runners*, the earth to be well loosened about them, a little drawn up to the stems, and then staked at once. Continue the gradual thinning of Carrots and Onions as they may be required for use; but Parsnips, Red Beet, Salsafy, and Scorzonera should always be thinned to the proper distance at once.

FLOWER GARDEN.

Keep a watchful eye on the beds and borders, and where blanks appear let them be filled up with some of the reserved stock. Newly-laid turf to be watered, and if suffering strewn some light litter slightly over to break the sun's rays. Top the gross shoots of Roses, and peg down others where necessary, and use the garden-engine freely to disperse insects, and to feed the roots. Dahlias to be well watered during dry weather, and earwigs to be trapped as soon as possible. Roses may be budded, taking eyes from these trees which have been forced. The young wood from the same trees put in as cuttings will strike freely.

Pnt Pink pipings in light, rich soil on the north side of a wall or fence. Carnations, Picotees, and herbaceous plants, with the taller-growing bedding plants, to be staked and tied up, to prevent injury from high winds.

FRUIT GARDEN.

The recent hot weather has brought out the insect tribe in abundance, and they must be met with timely remedies. A powerful garden-engine should be kept in frequent use amongst the trees and bushes infested with aphides and honey-dew. Continue to stop, regulate, and lay in shoots of wall trees. Stop Vines, and tie in the shoots. Employ sulphur on the appearance or suspicion of mildew.

STOVE.

A little fire heat is necessary occasionally, in order to air freely, and to be enabled to continue a humid, kindly interior atmosphere, which will greatly encourage a sturdy healthy growth. Attention to be given in shading the plants from a scorching sun; to watering, syringing, and applying manure water occasionally.

GREENHOUSE AND CONSERVATORY.

When Orange and Camellia trees are kept in-doors, give abundance of air night and day; wash them frequently with the syringe, using clean water, and damp the paths and floors often. Specimen and choice plants nearly done blooming to have their faded blooms picked off, and to be well washed with the syringe; to be then placed in a cool, shady situation to recover themselves before potting, which, as before advised, should on no account take place until a fresh growth has commenced. Shading for the plants in bloom will be necessary, unless the roofs are covered with creepers. Air to be admitted freely by night in accordance with the description of plants grown, and the paths and floor to be kept damp by throwing water repeatedly over them to produce a humid atmosphere in the house.

W. KEANE.

DOINGS OF THE LAST WEEK.

In the kitchen garden hoeing, forking, and moving ground, and thinning Onions, Carrots, &c., were the principal work. The ground has as yet received only a sprinkle of rain on the surface, so that thinning, &c., has been attended with less dispatch than if the ground had been more moistened, and waiting later would be apt to injure the crop left. Watered forward Cauliflowers with manure water, and covered the ground with mowings from the lawn thick enough to keep most of the moisture in the ground; and if rain comes, what will pass through it after or during heating a little will do no harm. Find this also a capital plan for a quarter of early Cabbages in such a dry season as this has been lately. Even bedding plants would say nothing against it, if it were not for the look of the thing. Wide Celery-beds that had been filled with bedding plants to harden off were got cleared ready for the first Celery out of doors. Picked out more on borders for future transplanting. Have none, as yet, requiring earthing up as a general crop, as some people seem to have, from writings and inquiries made; and if we had a little rather forward for kitchen use, we should not think of earthing up any other in the first week in June, unless we wanted bolted heads, instead of nice, sweet, solid Celery. Stopped early Peas to cause them to swell their pods more freely, having found the Tom Thumb Peas in pots very useful and rather continuous bearing, if the pods were gathered rather closely, and not allowed to get old enough for stewing. Threw some dirty salt among Sea-kale and Asparagus, merely enough to slightly cover the ground. This not only assists the crops but is no bad thing for checking weeds.

The rains, as yet, being merely the lick of a promise, have been forced to give the most of the Strawberries a good soaking with manure water, having previously surface-stirred the ground to cut up germinating weeds and fill up all cracks, and then covering the space with long litter. Strawberries in houses frequently want water twice a-day, and most are now cleared out under protection of glass. A small border has been covered with old spare sashes. Twelve-inch pots are merely placed at back and front, some 6 feet or 8 feet apart, a rail placed on them, and the sashes lie on the rail back and front. A board 9 inches deep or so goes against the pots, back and front, which in sunny weather gives enough of air and keeps in a good deal

of heat. In sunny weather this hastens the ripening; in dull weather it is pretty well labour thrown away. It is well to fully expose if the weather is fine a day before gathering, in order to communicate flavour. Everything betokens a fine crop of Strawberries this season, and early runners for next season's forcing.

We holloaed before being quite out of the wood in speaking of the abundance of Gooseberries, Currants, and Plums last week, and their freedom from insects; for only a few days past and some caterpillars began to appear on the former, and fly on the latter. Some of the berries of Gooseberries were encrusted with fly, the ends of the young shoots began to curl up and hold hundreds in their folds; and the leaves of the Currants began to turn yellow in two or three places, and their points to be similarly affected as the Gooseberries. The first thing done was, to nip off in a basket the mere points of the Gooseberry shoots the most affected, and which of itself would be an advantage, and any redundant young shoots not wanted, and then wash bushes and trees well with lime and soot water. This has pretty well cleared off the hosts of invaders. I notice in a few places there are still some caterpillars left; and these must be looked for, shaken off and then destroyed, or the places powdered with lime and soot. The first is the best plan; for if the lime and soot are caustic enough to kill the caterpillar as well as make it drop, it is apt to affect the cuticle of the berry so much as to prevent it swelling freely and ripening kindly. Fly also appeared among Plums where the fruit was thickest, but the drenching has pretty well cured them; and picking and washing have nearly driven the caterpillars from Cherries and Pear trees, which I never knew so numerous as this season, notwithstanding the severity of the winter. Watered Figs again with manure water, which are now swelling kindly and ripening; must shorten and regulate shoots as soon as possible. Watered Peaches, &c., in pots in orchard-house, and nipped the points of the shoots, and tied, stopped, and nipped off a few leaves to expose the fruit freely in Peach-house, now nearest the fire, beginning to ripen, though no fire has been given in the warm nights of late. Thinned out a few laterals from the earlier vineries, and tied down the shoots in the late house, as the young bunches just setting and coming into bloom were getting against the glass, there being so much to do at the end of May and the first fortnight in June. Melons and Cucumbers stopped and regulated, and watered as required; and prepared for planting as soon as possible strong plants of pickling Cucumbers, Vegetable Marrows, and hope they will do better than last year. Strong plants of Tomatoes in large pots, are also crying out to get into their summer quarters. Where walls are scarce, a fence, a sloping bank, or even a south border will grow them well, if the plants are kept well thinned and stopped.

In the plant way the verandahs have been set out, and the conservatory fresh arranged, removing the whole of the Cinerarias, Primulas, Camellias, and earlier Azaleas, Geraniums, &c., and supplying with Fuchsias, Pelargoniums, Scarlet Geraniums, &c. The forwardest Azaleas were placed in a yard with the protection a good height above them of thin Nottingham netting; those just finished blooming were given one end of the conservatory to themselves, where they could be kept a little closer and have the syringe pretty freely before they made fresh growth and began to stop for flower-buds. Cytisus, &c., past their best, were placed in the open yard with the wall in front of them, just to break the force of the sun's rays for a little time, and far enough apart to permit of the syringe freely among them; freedom from red spider being essential to their healthy appearance and free flowering. Moved the last of the Camellias in pots almost done blooming to the late vinery, where the fresh growth will receive a little encouragement before the plants will go out of doors for the season. Kept potting stove and greenhouse plants as needed, and commenced potting such common things as Perilla, and small Geraniums, for summer and autumn decoration; the chief work, however, being getting forward with the bedding plants, and keeping these all right, by syringing and watering, the labour of which has been lessened since the 31st ult., by the weather being more dull and threatening to give the soaking rain that seems so loath to come. This ease from labour in watering has the disadvantage of not causing the ground to get warm so soon as in bright sunshine, and, for bedding plants especially, where not one in a hundred comes from a pot, but is lifted from an intermediate-bed and planted at once, a warm soil is a great essential to quick and healthy growth. Even in

hot days a little water will go a great way if judiciously given; for, provided the roots have enough, not a drop more should be given, as the soil becomes cooled first by the water, and then still more by the evaporation caused by it. In cases of importance, it is best to remove the dry surface soil, give the little water needed, and in half an hour or less replace the dry surface soil, to lessen evaporation and the cold produced by it. When the soil about the roots is damp enough, and young plants are still disposed to flag, a little shading or a slight dewing of the foliage is far more useful than delugings of waterings. In sprinkling, the little that falls on the hot surface of the ground rises about the foliage ere long as warm vapour. For maintaining regular unbroken beds, even in such cold stiff soil as is here, and without scarcely any filling up after once planting, I have just too little secrets, now secrets no more—the above plan as to watering, and giving almost every plant a little of the light warm compost referred to the other week, even though that should scarcely be half a handful or a quarter of one. Raising the plants from beds, instead of planting from pots with balls, is also another help, though sometimes the plants suffer more from hot weather at first. One item more as respects Calceolarias is to get them out before they are too forward. A friend told me he planted some hundreds the other day from pots and in full bloom, making a fine bed at once. I hope they may go on; but there is the risk, if the ball was not broken on the outside well, that they might cease to bloom, or cease to thrive by the middle of the autumn.

In laying such stress upon limited waterings in the above case, we wish beginners clearly to understand that it applies to such cases alone, and not to waterings in general to fully-established plants. In their case the general rule is, Water so as thoroughly to moisten the earth about the roots, and water no more until another thorough watering is needed. In such cases mere frequent surface sprinklings do more harm than good—surface roots are merely encouraged to be burned up with a powerful sun; whilst, so long as the surface of the soil is moist, the lower roots will have less chance of obtaining moisture from beneath them until the surface becomes again comparatively dry. Merely refreshing the foliage with a sprinkling is quite a different thing, and is very refreshing in the evenings of hot weather. After a slight shower, under such circumstances, even though the surface of the ground is little touched, how fresh everything looks! This is very different from watering a bed every day with the rose of a watering-pot: circumstances must, therefore, be our guide; and what I wish to impress is, the different watering new-planted-out flower-beds should receive contrasted with the deluging we should give to a quarter of strong Cauliflower plants.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

KIDDEAN SYSTEM (*Stupid Fellow*).—This is not ripe yet for drawing. The original was a great vault made fireproof under the drawing-rooms, and 10 feet or 12 feet from the end of the conservatory, the hot-air passage rising rapidly on the slope, and the structure cost over £200 of the public money, perhaps twice as much; but it all ended in smoke, the vault was full of smoke every time the thing was set to work, and there it ended, and no one could make it work. Mr. Kidd pulled the structure to pieces, and Mr. Beaton explained how he did it sufficiently for those who understand such things to be able to make a new one. Others had better not try it till the best practical application of it is found out, and is proved by actual practice, then we shall give a drawing of it. We publish to-day drawings of the mode in which a correspondent has carried the Kiddean mode of heating into effect; this may aid you.

GERANIUM LEAVES (*Sarniana*).—Your variegated leaf is very pretty indeed, and comes very near the Queen's favourite, and the whole class of tricolor-leaved Geraniums, one of the three colours being pink or crimson; but it is very difficult to transmit the markings by crossing. Your other leaf is, we think, that of the type of Mangles Variegated, and, if so, that kind will not cross in England; but give it all the chances you can, and let us hear how you succeed with it in the climate of Guernsey.

CLAY ON A CLAY SUBSOIL (*R. W.*).—Yours is the worst of bad soils for gardening. The most effectual way to improve it is to burn a full spad's depth of the surface, and dig in the ashes thus obtained with the spade's depth of soil next below. This with the admixture of bricklayer's limy rubbish, coal ashes, and road scrapings, if from flints mixed with the soil, will improve its staple, and, as it is well drained, ought to give you good crops.

HINT TO MR. BEATON (*Ignotis*).—*Hippocrepis comosa*, neat habit, bright colour, very fragrant. Much obliged. The seed-pods are also most curious, queer-looking, crooked horns. Please send us a pod or two when the seeds are ripe. It is a pretty, dwarf yellow pea flower, and grows best on our chalky downs.

RARE EDGING PLANT (*H. X. W.*).—The little plant which makes you "a very neat edging," is the oldest we know. We have not seen it since May, 1821. Mr. N. Niven, now of Drumcondra, near Dublin, had it then in Belladrum, above Inverness, and he had it in a damp, low situation, intensely shaded by trees. He said it would grow only in that way. Pray tell us the exact circumstances under which it has made the neat edging; for it is the prettiest leaf of all the hardy decorative plants we know, and an edging of it must look as if made all of Cyclamens. The old garden name of the plant was Virginian Asarabacca, and it is the *Asarum virginicum*. The flower has no petals; but the calyx, which is in three parts, is thick and leathery, of a dark purple colour, and is not seen on account of the leaves. If you would kindly send a root or two of it, we will put it into the hands of Mr. Beaton, who would put us, probably, in the way of having a very neat edging of it.

TREATMENT OF NEGLECTED VINES ON A WALL (*G. S. N.*).—Without seeing your Vines it is almost impossible to advise you what to do with them. From what you say, we conclude that you can do nothing to the roots except stirring the surface, and giving a good soaking of tepid liquid manure twice or three times during this summer, and keeping the surface mulched. From the fact that the Vines are unfruitful, we are led to think that there has been too much wood left annually. Should that be the case, thin out now the young shoots very severely, cutting off close to the old wood. Go over the whole of the Vines, and just leave as many young shoots as will have room to expand their leaves; and leave portions of wall exposed to be warmed by the sun. Let the shoots that are left be stopped at the fifth leaf, or thereabouts; and as the laterals break at the sides, stop them at the first joint. Stop these again, and again during the summer, and keep each young shoot close nailed to the wall: the object of this pruning, stopping, and training close to the wall is, to fill the buds, and ripen the wood, without which any Vine will be barren for ever. The Vine on the south-west aspect should have the bricks taken away from the stem, a sufficient distance to allow the manure water to get down to the roots. Are you sure the borders are dry at the bottom? It is very likely Mr. Appleby will shortly give instructions how to treat old Vines where the owner wishes to preserve them; but the operation of lifting them, making a fresh border, and re-planting, is best done in the autumn, so you will have time enough before you. In the meantime, summer-prune your Vines, keep the shoots wide apart, and get the wood well ripened as early as you can. If there are no bunches shown already, you need not expect any this season.

ENTOMOLOGICAL WORK (*H. Jones*).—Kirby and Spence's "Introduction to Entomology," is the best elementary work we know.

WHITE HELLEBORE POWDER (*O. P.*).—Dusting this over Gooseberry bushes to destroy the caterpillars upon them, is not in the slightest degree likely to render the fruit poisonous. Washing the fruit previously to bottling it would remove every particle of the powder. We have used the powder many times. It should be recently prepared, for hellebore powder if old is apt to lose its efficacy.

BOXES FOR EXHIBITING CUT ROSES (*Rose*).—As the petals of the adjoining specimens should just touch, you had better cut a truss and give space according to their size. The same test may be applied to determine the depth, the length of the stalk does not require more than 6 inches. Have oblong boxes, made with a moveable cover; this cover or lid to have sides to it deep enough to keep the lid clear from the Roses. The lower part of the box should have a division-board resting upon a ledge of wood; this board should have holes in it wide enough to admit tin or zinc bottles through them, and these bottles should have a flat rim wider than the hole, for them to rest upon the board, and so prevent them slipping through. If the bottles fit pretty tight, so much the better; but as the board is moveable and can be lifted out, should any of the bottles feel loose they may be wedged tight with chips of wood from the under side. The lower part of the box should be deep enough to allow the bottles to hang clear of the bottom; if this were not so they would be pushed upwards, and the Roses spoiled. The box being so made, and fitted with bottles placed at such distances as to allow the Roses to be put in them so as not to touch each other, let the whole have two or three coats of paint, the last being a pleasing grass green. This ought to be done time enough to allow the paint to become perfectly dry before the day of exhibition.

RAISERS OF FLOWERS (*C. Brown*).—You must excuse us for declining to search for this information. If you refer to some old florist's catalogues you will find the names of the raisers in parentheses.

NAME OF TREE (*G. S. E.*).—It is *Pyrus aria*, the White Beam Tree. Nothing shuts out an unsightly object so soon as a trellis, and Ivy turned out of pots, which are to be had at all large nurseries, and may be planted now. We cannot name any trees, for we do not know either the soil or situation, or county even where they are to grow.

GREEN FLY ON GOOSEBERRY BUSHES (*M. K. J.*).—Syringe them with Gishurst Compound two ounces to the gallon of water, and repeat: the syringing every second day until the insects do not reappear. All of the mowing machines advertised in our columns are good. We cannot recommend florists. Tan spread over Strawberry-beds will answer for keeping the fruit unslashed.

ROCKETS (*A. J.*).—Merely the common Rockets to be obtained of any nurseryman.

ROOT-PRUNING FRUIT TREES (*Clericus*).—The best time is as soon in autumn as the fruit on the trees is ripe. Cutting the roots then—say October, will influence the trees the first season, less or more. If the trees are in a state of rest it will not influence their fruitfulness until the second summer.

GERANIUM LEAVES INJURED (*H. H. R.*).—We can think of no cause but the leaves being damp when the sun has shone brightly upon them. The sponging is a capital thing in London, but in the case of Pelargoniums the leaves should be dry before the sun reaches them. We hope the pots are not allowed to stand in saucers half full of water.

GAZANIA SPLENDENS IN POTS (*R.*).—The *Gazania* is worthy of a place in the greenhouse and the flower-bed likewise. It naturally trails, but to prevent being hurt by winds, it would be as well to have a few pegs to keep

it firm. That in the greenhouse should have a sunny spot. It will propagate as easily, or rather more so, than the Verbena. If you had a spare hand light in a shady corner, every bit put beneath it an inch or two in length in sandy soil in summer, would soon root. Small pieces also root quickly in heat in spring.

PROPAGATING DIELYTRA SPECTABILIS (Idem).—The *Dielytra* is easily increased three ways—first, when the plants are done blooming, cut up the stalks into pieces and insert in a cool shady place under the protection of a hand-light; second, when the shoots rise and are about 2 inches to 3 inches long in spring, they strike very fast in a little heat; and thirdly, by dividing the roots when at rest or just beginning to move, like a dahlia root.

VARIETIES (Jin-crack).—We would not advise planting Vines in tan however old. It contains too much acid. We suspect either that the Vine roots have descended deeper than you suspect, or that the wood was imperfectly ripened last autumn. Lessen growths this season by keeping the Vines pretty free of laterals, and give a little extra fire heat with plenty of air in autumn in order to harden the wood well before the leaves fall. Collect the snails after you have laid down brewer's grains or leaves of cabbage or lettuce smeared with fat, to entice them to congregate in heaps. Pot your Camellias either as soon as they make fresh growth, or immediately after they are stopped lengthening, which you will know by the hardness of the terminal bud. The best to suit your purpose as a climber we should judge to be *Cobaea scandens*.

MILDEW ON VINES (Curate).—Although it still appears on your Vines, yet it cannot progress if you keep the Grapes and leaves dusted with flowers of sulphur. We cannot advise more as to your Vines than painting your heating medium with a creamy mixture of sulphur and lime; but it a flue, putting none on for three or four yards from the furnace, and even hot water should not be above 170° in the pipes, if you put on them the sulphur mixture. With your copious watering, if you had not given so much air, we should have attributed the seizure to too close and damp an atmosphere. You must just continue the dusting, and giving plenty of air and less moisture in the air of the house.

PLANTING OUT HERBACEOUS CALCULARIA SEEDLINGS (Idem).—You may with propriety set or plunge your *Calcularia* plants in pots under a north wall in sand or coal ashes as you propose; but we would rather propose making a raised border of silver sand, peat, leaf mould, and loam, in equal proportions, and turning out the plants in it. If healthy, now and kept healthy, they will finish you with plenty of sucker-like young plants in the autumn.

GRAPES SHANKING—PROPAGATING-PIT (H. A. L.).—Such effects on Vines are produced by too heavy crops, and from the roots being too deep. Either a dung-heated frame or a flued pit is best, accordingly as best managed. A nice pit would be 3½ feet high at back, and 2 feet 3 inches in front, and a foot below the ground level, and 5½ feet wide; walls 9 inches thick, heated by a flue 9 inches wide, and two bricks on edge for the sides. We have recently told everything about making flues, using cement pipes, &c. For comfort and convenience we would recommend a span-roofed little house, or even one facing the south, with a lipped-roof, so that you could do everything under cover. Thus supposing you had a space 9 feet wide, you might sink it a little under the ground level, or have it on the surface level, which would be least trouble; form two side walls 3½ feet high, and a ridge-board 7 feet high, rafter sash-bars 2½ inches by 1½ inch would be strong enough, 15 inches apart to receive glass of that size, with either a double ridge-board, with ventilators between them, or every other square in the ridge made to open. Two side walls inside would form your pathway 2 feet 6 inches wide, leaving rather more than 3 feet for a bed on each side. The flue could enter at one side below the bed, go round the other to the chimney, a concrete or loose bed over the flue would enable you to do anything with it as to heat or propagating, but such a flue in such a house if 20 feet long, ought to be brick-on-bed for a quarter of its length. The mode of concreting or nailing open rubble has frequently been told. In such a house a few ventilators should be secured in the side walls.

EARTHING-UP POTATOES (G. L.).—This practice is objectionable because it retards the ripening of the crop. If the earth is drawn up to the stems in a high pyramid, as is usual, the retardation is a full fortnight, and is evidently occasioned by the plant pushing forth fresh root-growth into the soil thus raised about the stems. The earlier the crop of Potatoes ripens the more likely is it to escape the murrain; therefore, the check thus occasioned ought to be avoided. If your Potatoes are planted shallowly there would be no objection to drawing an extra inch depth of soil up to the stems, so that the tubers may not appear through the surface.

FUMIGATING PLANTS.—*Rose Garden* writes to us as follows:—"Some time ago, one of your correspondents gave us his invention of a plan for smoking plants in borders, and promised to inform our readers how to smoke standard Roses. Now, although I have been looking very anxiously, week after week, I have not yet seen his promise fulfilled. Could you give us any plan, as my Roses are now beginning to be terribly infested with the horrible green fly? Will your correspondent send us his promised communication?"

SPERGULA MILIFERA (A Correspondent).—It grows as well now as at the first on the strongest clay land, and not better than ever it did on all light lands. Mr. Carter has taken to the *Spergula* Nursery, and now prefers the saginoides for light soil, as the old *Spergula* cryptogamist pointed out long ago, and by seeds is the best way to raise it.

YOUNG MELONS TURNING YELLOW (P.).—This and their subsequent falling off are probably occasioned by the roots being too wet and too cool.

VARIETIES (Belgash Subscriber).—You will have seen that we recommend white hellbore powder for the gooseberry caterpillars. Build an ice-house any time so as to be ready for the first ice that is formed next winter. You will find directions for constructing an ice-house in the *Cottage Gardeners' Dictionary*, and by Mr. Fish, in our No. 558, which you can have from our office for 4d., free by post. Your bookseller is in fault; every copy required can be had at our office before twelve o'clock on the day of publication. We are obliged by the offer of translation, but we have it done already.

CONVERTING AN AQUARIUM INTO A FERNERY (Emma).—It will require a glazed top, and we recommend it to be an eight-sided cupola to correspond with the octagon form of the aquarium. If made moveable it will be very effective for ventilation. Flockwork is a great improvement to a miniature fernery. Messrs. Veitch & Son had a magnificent example of one at the Horticultural Society's fête on Wednesday last. Miniature ruins, which are sold ready made in Covent Garden Market, are very effective.

BUILDING A LEAN-TO GREENHOUSE (An Old Subscriber).—See whether the directions in Vol. XXIII. p. 347 will not suit you. By referring to that, to Vol. XIII. p. 59, and to "Greenhouses for the Many," any carpenter could construct the one you need.

TEA ROSE ACROBA (B. R. Cant).—The blooms sent are very beautiful, and the Rose is unknown to us. It seems allied to Cloth of Gold and the Noisettes. The colour a soft creamy yellow, very much that of the cream of rich milk, the shape good, and the foliage equal to that of Gloire de Dijon. If as you say, it is lost to the trade, it will be conferring a boon on Rose-growers to let it out again; and as the blooms sent are gathered from a plant in the open air, its hardness would still further enhance its value. The small Apple was in excellent condition, and in our opinion is a very valuable sort, as well for its first-rate quality for dessert use as for its late keeping.

NAMES OF PLANTS (J. L. S.).—Your "plant, with scent like the onion," is the *Ransoms, Allium ursinum*. It is very common, and is detested by cowkeepers; for if in pastures where their cows feed, it gives a garlic-like flavour to their milk.

FLOWER SHOWS FOR 1861.

- JUNE 11th. ROYAL OXFORDSHIRE HORTICULTURAL SOCIETY. (Plants and Flowers.) Sec., W. R. Hobbs.
JUNE 12th and 13th. YORK. Sec., J. Wilson.
JUNE 19th and 20th. BRIGHTON AND SUSSEX FLORICULTURAL AND HORTICULTURAL SOCIETY. Sec., E. Carpenter.
JUNE 25th. ROMFORD. (Plants, Flowers, and Fruit.) Sec., A. Cooper, Romford.
JULY 3rd. PORTSEA ISLAND. Sec., H. Hollingsworth, Southsea.
JULY 6th. CRYSTAL PALACE. (Rose Show.) Sec., W. Houghton.
JULY 10th. ROYAL HORTICULTURAL SOCIETY. (Rose Show.) Garden Superintendent, G. Eyles.
JULY 18th. TOWCESTER FLORAL AND HORTICULTURAL SOCIETY. Sec., T. B. Rodhouse, Towcester.
JULY 18th. PRESCOT. Sec., J. Beesley.
AUGUST 9th. BELFAST ROYAL BOTANIC AND HORTICULTURAL SOCIETY. (Plants, Fruits, and Vegetables.) Sec., George A. Carruthers.
AUGUST 14th. PORTSEA ISLAND. Sec., H. Hollingsworth, Southsea.
SEPTEMBER 2nd. HICKMOSDWIKE. (Floral, Horticultural, and Agricultural.) Sec., G. Kelley, Hickmosdwike.
SEPTEMBER 4th and 5th. CRYSTAL PALACE. (Dahlias, Cut Flowers of other descriptions, and Fruit.) Sec., W. Houghton.
SEPTEMBER 11th. ROYAL HORTICULTURAL SOCIETY. (Dahlias and other Cut Flowers.) Garden Superintendent, G. Eyles.
SEPTEMBER 18th and 19th. BRIGHTON AND SUSSEX. Sec., E. CARPENTER.
NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums.) Garden Superintendent, G. Eyles.
NOVEMBER 12th and 13th. STONE NEWINGTON CHRYSANTHEMUM SOCIETY. Sec., W. T. Howe.
NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show.) Sec., W. Houghton.

POULTRY, BEE, AND HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

- JUNE 19th. TROENE. Sec., Mr. Joseph Richardson. Entries close June 12th.
JUNE 19th, 20th, and 21st. COALBROOKDALE. Secs., Messrs J. B. Chuue, and Henry Boycroft, Coalbrookdale.
JUNE 25th. ESSEX. Sec., Mr. W. R. Emson, Slough House, Halstead, Essex.
JUNE 28th. DRIFFIELD. Sec., Mr. R. Davison. Entries close June 22nd.
JUNE 28th and 29th. TAUNTON. Sec., Mr. Charles Ballance. Entries close June 17th.
JULY 3rd, 4th, and 5th. BLACKPOOL AND WEST LANCASHIRE. Sec., Mr. E. Fowler, jun., Market Street, Blackpool. Entries close June 30th.
JULY 18th. PRESCOT. Sec., Mr. J. Beesley.
AUGUST 26th, 27th, 28th, and 29th. CRYSTAL PALACE SUMMER SHOW. Sec., Mr. W. Houghton.
SEPTEMBER 3rd. POCKLINGTON (Yorkshire.) Sec., Mr. Thomas Grant. Entries close August 26th.
SEPTEMBER 24th. BRIDGORTH. Sec., R. Taylor, Bridgnorth.
DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. Sec., Mr. J. B. Lythall, 14, Temple Street. Entries close November 1st.
DECEMBER 11th, 12th, 13th, and 14th. CRYSTAL PALACE WINTER SHOW. Sec., Mr. W. Houghton.
N.B.—Secretaries will oblige us by sending early copies of their lists.

RULES FOR SELECTING DORKINGS.

If your breed be Dorkings, choose them with large limbs and wide backs. When the chicken is held with the left hand, place the right flat on the back of it, resting on the hip bones, the width there will be a fair test of the size of the bird. A bird wide there is generally good elsewhere; while, on the other hand, it is impossible that a narrow-backed bird can either be full in hand, or satisfactory in the scale. It may not be out of place here to say, that although great weight is more than desirable in this breed, yet that more fact is not enough to gain prizes. Weight should be the result of size. The point has often been mooted, and it will no doubt be so again. It began in the early days of Cochins, and caused the poor birds to be fed on meat of every kind, to the detriment, if not the destruction, of their powers and usefulness as breeding-stock. Poultry shows are not held for the exhibition of fat stock. Choose chickens with well-developed, but not remarkably large, fifth toes and claws, with white legs; but it is not essential that they be of that dead milk-white that some would have. You may

go through many of the best yards in the kingdom, and you will not find one fowl with a faultless white leg, as a sort of brown or sepia tinge is common among them. If this covered the whole leg it would unquestionably be a disqualification; but it does not, it only stains the edge of the scales that cover the leg. The white leg is declared to be essential as distinguished from a black, blue, willow, or yellow. It is very desirable the breast should be straight. In choosing cock chickens take those that have full-sized legs, large round heads, strong beaks, and full eyes; choose them lengthy. Avoid anything like maturity in a chicken from which you expect growth. It should be as loose as a tall boy of fifteen.

Dorkings, save in the Silver Grey classes, are not tied to colour; but it is nevertheless quite as well to have those that are pleasing as those that are offensive to the eye; the best bird—that which limits every quality—is only good enough to win, and, therefore, even a very trifling defect, or the lack of some advantage possessed by a competing pen, may turn the scale.

Again, although it is not essentially necessary the hens or pullets in a pen of Dorkings should be the exact counterpart of each other, yet it is well they should be as much alike as possible. We do not believe in yards where all the pullets are so much alike you cannot tell one from the other; that can only be accomplished where they “breed well, and kill well.” Our experience tells us the white speckle will have its way. It comes on the back of the Silver Grey pullet, and on the breast of the cock; the latter also often shows the white feather in his tail. We sometimes buy the draft birds of one of our most successful Silver Grey breeders, and when we see the mixture of colour among them we always think of Brummel’s valet, who being met on the staircase of an hotel with a supper-tray full of scarcely-tumbled cravats, and being asked what they were, said, “They are our failures.” It is, then, advisable to keep colours that will help to successful exhibition. To accomplish this desirable end, everything in the poultry-yard should be made subservient to it, inasmuch as in the July arrangements the December and January contests should be borne in mind—not to make them anxieties, but to avoid the unavailing regret afterwards; the fatal, desolating “too late,” when the pen cannot be satisfactorily formed. “If I had saved those two pullets, or had not killed that young cock, I could have done better.”

While on the subject of Dorkings, we may as well advise any one who may breed a very good pen of rose-combed chickens to take care of them. There are yet people who doubt the purity of them, but the same nail up carefully-concealed horseshoes in different parts of their houses, and in solitary spots like to put a running stream between themselves and an old woman. In general breeding, do not discard a cock for white-spotted breast, nor for white tail, nor for clouded or dark hackle and saddle. There is no colour, and, therefore, none are barred except white and black. In these, as in other breeds where size is important, the birds must be always well fed; they must never be allowed to fall off. A chicken that has gone back, and recovered its ground, is, when convalescent, just where it was when it fell ill. That which has gone on uninterruptedly is all the time a-head. Scanty feeding is false economy; overfeeding is wicked waste. Both render success impossible.

BATH & WEST OF ENGLAND AGRICULTURAL SOCIETY’S MEETING.

HELD AT TRURO, CORNWALL.—June 4th, 5th, and 6th.

THE Bath and West of England Agricultural Society have now been for a number of years past notorious for the excellence of the poultry competing at their annual exhibitions; and although the selection of a show ground so distantly situated as Truro is from the yards of most of our principal breeders, had a tendency to limit the numbers of entries, we have great pleasure in stating, that the quality of the specimens of every variety of useful poultry exhibited, even surpassed all former meetings of this Society. This marked improvement in the utility of the poultry, was, indeed, the universally acknowledged fact among all present.

Messrs. Martin, Lane, and Fowler, who obtained the prizes for Black Spanish fowls in the consecutive positions in which we have named them, never exhibited better specimens of careful breeding.

The *Dorking* class comprised every variety of colour, which, of course, gave but remote opportunity of success to the White

ones; still it will be seen Mrs. Fookes, of Whitechurch, Blandford, Dorset, held her position as third prize with a pen of as good white ones as need be desired. The Marchioness of Winchester fairly ran away with the prize from her rivals in the Grey Dorkings, with that well-known pen of dark ones, of late so repeatedly successful. They elicited the warmest approval of every visitor; and her first-prize pen of chickens of 1861 were but little, if any, less worthy of our especial mention. The second prize in the Dorkings was carried off even under this truly severe competition by a resident of Cornwall—viz., Mr. Roberts, of Treval, near Torpoint: this gentleman’s birds were shown in first-rate condition.

The *Cochin* classes were capital. In Buffs, Mr. Tomlinson, of Birmingham, took first and third prizes, with two of his unusually good pens, Mrs. Fookes’ second-prize pen being a trio of as well-plumaged birds as could be desired. Mr. Chase, of Birmingham, showed a pen of White Cochins in the most perfect feather conceivable, and wrested the first premium from as goodly a competition of “Cochins of every colour, save Cinnamon and Buff,” as we remember to have yet seen anywhere, so far as the Partridge-coloured birds of Mr. Peplow Cartwright were concerned; but with these two exceptions the class, as a whole, was a failure.

The *Game* classes were well filled, and likewise superior; Black-breasted Reds, Brown Reds, and Black Game being, however, decidedly the most favoured.

In their class, Mr. Ballance, of Taunton, showed as good a pen of coloured *Malays* as possible, and also a white cock in the Single Cock class, both of which obtained first premiums.

The *Hamburghs*, with the exception of Mr. Lane’s Golden-spangled, Mr. Martin’s Silver-pencilled, and Lady Julia Cornwallis’s Silver-spangled, were unusually faulty throughout.

The best variety of *Polands* exhibited, were the Black ones with white crests.

The most prominent feature in the Extra Variety class was the White Spanish. This district seems especially famous for this curious breed. Messrs. Rodbard and Fowler tried well for the mastery in Spanish Chickens, Mr. Fowler taking precedence, but well run by both the second and third-prize birds of Mr. Rodbard. Each of these three pens, if then doing well, will be formidable rivals at our winter meetings. Mr. Charles Felton’s pen of Partridge-coloured *Cochin* Chickens were excellent, and Mr. Archer’s Black-breasted Red Sweepstakes Game Cock was an admirable specimen. Mr. Harvey Dutton Bayley completely silenced anything approaching competition in the Sweepstakes Bantam Cock class, by entering his well-known Black-breasted Red, the fellow to such a bird being, in truth, but scantily sown.

The Rev. G. S. Cruwys took three first prizes for three descriptions of Bantams—viz., Silver-laced, Gold-laced, and Black ones, against a host of rivals—a triumph in these closely-contested days to any poultry yard. The first-prize Bantams for “any variety” were capital Duckwings; they took this premium even though labouring under the no slight disadvantage of travelling from Glasgow to Truro to attain it.

To say Mrs. Seamons, of Aylesbury, won the Aylesbury *Duck* prizes is, indeed, a Cuckoo’s note, for her breed of these useful stock are unsurpassable. Mr. Fowler’s *Rouens*, and Mr. Sainsbury’s *Buenos Ayrean Ducks*, were equally praiseworthy.

The *Grey Geese* and the *Turkeys*, also, belonging to the Marchioness of Winchester, stood out “like giants” in their respective classes, and we ourselves heard many remarks of visitors expressive of astonishment that such birds really were existing.

Some peculiarly good *White Guinea Fowls* were also much coveted.

Although many of the *Pigeons* were shown in unusually good trim, perhaps the most praiseworthy were the Ice birds and a pen of Black Trumpeters; these last were a marvel to the fancy. The Runts, too, were first-rate ones.

Among the odds and ends, a pair of exquisitely plumed *Cornish Choughs* reigned supreme; they were as tame as the most domestic chickens, in the rudest of health, and, as stated in the text, were “everybody’s favourites.”

It will be seen they were specially acknowledged by the Judges, Dr. Cottle, of Cheltenham, and Mr. Hewitt, of Sparkbrook, Birmingham. The poultry was well-looked to by the Council, and prompt measures were adopted to secure quick transit on their long return journey.

SPANISH.—First, J. Martin, Mildenhall Mill, Claines, Worcester. Second, H. Laue, Bristol. Third, J. K. Fowler, Aylesbury. Highly Commended, R. Wright, Holloway, London. Commended, J. B. Fowler.

DORKING.—First, Marchioness of Winchester, Andover. Second, R. W. Roberts, Cornwall. Third, Mrs. H. Fookes, Dorset. Highly Commended, E. Burton, Cornwall; J. K. Fowler, Aylesbury; C. H. Wakefield, Worcester-shire. Commended, G. Chadwin, Salisbury; Lady J. Cornwallis, Kent.

COCHIN-CHINA (Buff or Cinnamon).—First and Third, H. Tomlinson, Bir-mingham. Second, Mrs. H. Fookes, Dorset.

COCHIN-CHINA (any colour except Buff).—First, R. Chase, Birmingham. Second, J. Cartwright, Hampshire. Third, (withheld.)

GAME (White and Piles, Blacks and Brassy-winged).—First, J. Fletcher, Lancaster. Second, W. Dawson, Birmingham. Third, Rev. G. S. Cruwys, Devon.

GAME (Black-breasted and other Reds).—First, J. Fletcher, Lancaster. Second, S. Matthew, Suffolk. Third, W. Rogers, Suffolk. Commended, Rev. G. S. Cruwys, Devon.

GAME (Duckwings and other Greys and Blues).—First, S. Matthew, Suffolk. Second, Rev. G. S. Cruwys, Devon. Third, W. Dawson, Bir-mingham. Highly Commended, W. Long, Devizes.

MALAY.—First, C. Ballance, Taunton. Second, G. F. Nicholls, Cheltenham. Third, J. Rumsey, Hackney, Middlesex.

HAMBURGH (Golden-pencilled).—First, The Marchioness of Winchester, Andover. (Second and Third withheld.)

HAMBURGH (Silver-pencilled).—First, J. Martin, Worcester. Second and Third, T. Keable, Berks.

HAMBURGH (Golden-spangled).—First, W. R. Lane, Birmingham. Third, W. A. Elliott, Plymouth. (Second withheld.)

HAMBURGH (Silver-spangled).—First, Lady J. Cornwallis, Kent. (Second, and Third withheld.)

POLANDS (Black, with White Crests).—First and Second, T. P. Edwards, Lyndhurst, Hants. Third, G. Ray, Lyndhurst, Hants. Commended, Miss E. de Conicy Devar, Dublin.

POLANDS (Golden and Silver-spangled).—First and Second, E. Carlyn, Cornwall. Third, E. Carbis, Cornwall.

ANY VARIETY NOT COMPRISED IN THE FOREMENTIONED CLASSES.—First, Miss S. H. Northcote, Exeter (White Spanish). Second, J. Martin, Corn-wall (Cuckoo Fowls). Third, The Marchioness of Winchester, Andover (Brahmas). Highly Commended, E. Burton, Truro (Minorcas); J. K. Fowler, Aylesbury (Brahmas); J. Davey, Cornwall (Silver Pheasants). Commended, J. H. Craigie, Essex (Brahmas).

SPANISH CHICKENS (Black or White).—First, J. K. Fowler, Aylesbury. Second and Third, J. R. Rodbard, Aldwick Court, Wington, Bristol.

DORKING CHICKENS.—First, The Marchioness of Winchester, Amport St. Mary's. (Second and Third, withheld.)

GAME CHICKENS.—First and Second, withheld. Third, J. Fletcher, Stone-clough, near Manchester.

COCHIN CHICKENS.—First, C. Felton, Erdington, Birmingham. Second Mrs. H. Fookes, Whitechurch, Blandford, Dorset. Third, J. K. Fowler, Aylesbury, Bucks. Commended, J. K. Fowler, Aylesbury.

SWEEPSTAKES.

GAME.—First, E. Archer, Malvern. Second and Third, J. Fletcher, Stone-clough, Manchester. Highly Commended, W. D. Braginton, Knapp, Bideford, Devon; J. R. Rodbard, Aldwick Court, Wington, Somerset.

DORKING.—First, Mrs. N. Grenville, Butleigh Court, Glastonbury. Second, G. Chadwin, Tollard Royal, Salisbury.

MALAY.—Prize, C. Ballance, Taunton.

GAME BANTAM.—First, T. H. D. Bayley, Ickwell House, Biggleswade, Beds. Secord, J. Camm, Farnsfield, Southwell, Nottingham.

BANTAMS (Gold-laced).—First, Rev. G. S. Cruwys, Cruwys Morchard Court, Tiverton. Second, T. H. D. Bayley, Ickwell House, Biggleswade, Beds. Third, E. Burton, Truro, Cornwall. Commended, Rev. G. F. Hodson, North Petherton, Bridgwater.

BANTAMS (Silver-laced).—First, Rev. G. S. Cruwys, Cruwys Morchard Court, Tiverton. Second, T. H. D. Bayley, Ickwell House, Biggleswade, Beds. Third, Miss G. Everett, Gibraltar Cottage, Monmouth.

BANTAMS (White and Black).—First and Second, Rev. G. S. Cruwys, Cruwys Morchard Court, Tiverton. Third, T. H. D. Bayley, Ickwell House, Biggleswade. Highly Commended, J. Catell, Mosely, Birmingham. Com-mended, G. J. Dowrick, Truro.

BANTAMS (any other variety).—First, A. Campbell, Blythwood, Renfrew, Scotland. Second, J. Camm, Farnsfield, Southwell, Nottingham. Third, E. Burton, Truro. Highly Commended, R. Liscambe, Tamer Brewery, Devon-port. Commended, J. Mapplebeck, Moseley Road, Birmingham.

DUCKS (Aylesbury).—First and Second, Mrs. M. Seamons, Hartwell, Ayles-bury. Third, E. Carlyn, St. Austell, Cornwall.

DUCKS (East Indian).—First and Third, G. S. Sainsbury, Rowde, near Devizes, Wilts. Second, Marchioness of Winchester, Amport St. Mary's.

DUCKS (Rouen).—First, J. K. Fowler, Aylesbury, Bucks. Second, E. Burton, Truro. (Third, withheld.)

DUCKS (any other variety).—First, T. H. D. Bayley, Ickwell House, Biggles-wade, Beds. Second, E. Burton, Truro.

GESE.—First and Second, Marchioness of Winchester, Amport St. Mary's. Third, G. Williams, Scorrier, Cornwall.

TURKEYS.—First, Marchioness of Winchester, Amport St. Mary's. Second, Miss J. Milward, Newton St. Loe, near Bath. Third, G. Williams, Scorrier, Cornwall. Highly Commended, E. Carlyn, St. Austell, Cornwall. Com-mended, J. Chapman, Kelliseth, St. Erme, Cornwall.

GUINEA FOWLS.—First, G. Williams, Scorrier, Cornwall. Second, H. Adnicy, Lymstone, Devon.

PIGEONS.

CARRIERS.—First, F. G. Stevens, Axminster, Devon. Second, no com-petition.

ALMOND TUMBLER.—First, F. G. Stevens, Axminster, Devon. Second, Marchioness of Winchester, Amport St. Mary's.

TUMBLERS (any other variety).—First, F. G. Stevens, Axminster, Devon. Second, withheld. Third, C. H. Venn, Truro.

POWTERS.—First, F. G. Stevens, Axminster, Devon. Second and Third, J. Martin, Treweeke, Stithians, Cornwall.

RUNTS.—First, F. G. Stevens, Axminster, Devon. Second, E. Pigeon, Lymstone, Devon. Highly Commended, J. Davey, Camborne, Cornwall.

JACOBS.—First and Second, F. G. Stevens, Axminster, Devon.

FANTAILS.—First, Miss J. Milward, Newton St. Loe, Bath. Second, F. G. Stevens, Axminster, Devon. Commended, Marchioness of Winchester, Amport St. Mary's; J. Davey, Camborne, Cornwall.

OWLS.—First and Second, F. G. Stevens, Axminster, Devon.

TEMPLEPIERS.—First, F. G. Stevens, Axminster, Devon. Second, J. Davey, Camborne, Cornwall. Commended, F. G. Stevens.

BARBS.—First, F. G. Stevens, Devon. Second, J. H. Craigie, Woodlands, Chigwell, Essex.

TURBITS.—First and Second, F. G. Stevens, Axminster, Devon.

NCS.—Prizes withheld.

DRAGONS.—First, F. G. Stevens, Axminster, Devon. Second, J. F. B. and Newton Abbot, Devon.

ARCHANGELS.—First and Second, F. G. Stevens, Axminster, Devon.

ANY OTHER NEW OR DISTINCT VARIETY.—First, F. G. Stevens, Axminster, Devon (Iceland). Second, J. Davey, Camborne, Cornwall (Magpies).

Mr. J. Pearce, Ferris Town, Truro, Cornwall, a collection of Rabbits.

Mr. Pearce's Black and White Buck and Doe are highly Commended; also, his peculiarly good Grey Doe.

The Cornish Choughs, Pen 311, could not compete in the general classes, but on account of their rarity and most excellent condition they are highly appreciated and commended by the Judges.

POISONED FOWLS.

"My fowls are poisoned!" These words were uttered by one of my neighbours when he found one of his fowls dead; and no doubt it was poisoned, for there was every symptom of its having eaten poison, yet I have no doubt he was wrong when he said, "Some evil-disposed person has done it."

Housekeepers are too much in the habit of buying and using packets of "vermin destroyer" to enable them to get rid of mice and other vermin; and afterwards, if they find a dead mouse in any of the rooms, away it goes to the ash-pit, or any other out-of-the-way place; in a few days it becomes putrid. The first fowl which finds it tries to eat it, and often succeeds in doing so, and then, in the course of a few hours, the fowl is dead.

A weaver who is a poultry-keeper, and has kept poultry for more than thirty years, informs me that he has lost more fowls during the last five years from the above cause than he has lost during his lifetime from all other diseases. A youth, who pays great attention to the wants of his Bantams, one day saw one of them eating a poisoned mouse which had been thrown out of a dwelling-house; in a few hours afterwards he found the Bantam dead. I have seen a dead weasel retaining its hold of a dead mouse, I took it by the tail and pulled, and it drew the mouse after it. I felt desirous to know the cause of their deaths. On inquiry I found that a packet of vermin destroyer had been used in a neighbouring cottage the day before; and I have no doubt but that the mouse had eaten a portion of the poison, and had been caught by the weasel as soon as the blood of the mouse had taken up the poison, and both of them died.—R. S.

MANAGEMENT OF PARROTS.

In reply to your inquiries on this subject I send you the result of my own experience, feeling glad of the opportunity of contributing even in this trifling degree to your interesting Journal.

Mine is a Parrot of the Australian breed, called a "Green Leek," an elegant bird,* not large, and of a brilliant plumage. It has been in my possession sixteen years.

Its usual food has been hempseed and dry bread, with fresh water supplied every morning, at which time the cage is also carefully cleansed. Occasionally an almond, nut, or raisin may be given with advantage; but no flesh meat. When moulting I give a little Cayenne, or preserved ginger, or anything of a warm nature.

The water-trough should be roomy, as the bird enjoys its bath, especially in summer.

This Green Leek of mine has had within the period alluded to (sixteen years) three or four fits; to relieve which warmth is necessary, and a little flannel, dipped in eau de Cologne, applied to the body. I give my bird a swing, in which he greatly de-lights, and when exposing his cage to the sun, I always take care to protect it by a covering.—S. A.

TAUNTON AND SOMERSET POULTRY ASSOCIATION.—We are glad to hear that there is every promise of establishing a first-class and permanent show at Taunton, although the money prizes are not high. The prize list in its extended classification

* This species do not rub their beaks against the wires of the cage.

meets with general approbation. The entries are already very numerous in every class. The great attraction is, undoubtedly, the "thirteen pieces of plate," value £2 2s. each, most of which will be gained by the small entry-fee of 4s., and some of them for only 2s. 6d. They consist of handsome vases, cake baskets, fish slices and forks in cases, spoons and forks of all sizes, salvers, &c. The entries will close positively on June 17th.

THE CANARY AND THE BRITISH FINCHES.

(Continued from page 127.)

11. THE MOUNTAIN SPARROW (*Fringilla montana*).

German, Der Feldsperring.

French, Le Fringet.

THE Mountain Sparrow, known also as the Tree Sparrow, although not so common as the House Sparrow, is nevertheless often met with in many parts of England.

In plumage the Mountain Sparrow somewhat resembles a cock of the common or House Sparrow: it is, however, rather smaller, and the male and female are so nearly alike as not to be distinguishable apart. By comparing them, the cock has rather a clearer ring round the neck. The top of the head in both sexes is dark reddish-brown; the cheeks white with a black patch, and a black spot under the beak; the upper part of the body is reddish-brown with blackish marks in the feathers, like the House Sparrow; the quill-feathers of the wings and tail are nearly black, the under parts of the body being dingy white. They are active, restless little birds of social habits—rarely found in towns, but prefer orchards. Their nest, which is built principally of hay, is much like the common Sparrow's, and is usually placed in a hollow tree, or in a hole in an old ruin or cleft of a rock. The eggs, from five to seven in number, are light grey, with dark grey and reddish marblings. They feed principally on insects. Mr. Bechstein, in speaking of their usefulness, says, "Their flesh tastes even better than the House Sparrow's; and where a pair take up their abode in an orchard, they should by no means be driven away, on account of the exceeding great good they do, particularly when they have young. Both parents fly all day from tree to tree, and collect in spring from the buds and flowers, and in summer from the leaves of the fruit trees, the destructive caterpillars and insects." Though their food consists chiefly of caterpillars, cockchafers, grasshoppers, and many other insects, yet in autumn they will also take tithe of oats, barley and wheat, as well as other seeds; and in winter they will come into the farmyards for hay seeds and scattered grain: still they must be considered of greater benefit than harm.

Their song, if such it may be called, is not unpleasant; it is composed of a running string of chirps, somewhat in Sparrow fashion, with some sprightly and pleasing intonations. Their call also resembles the common Sparrow's, but shriller, and sounds something like knocking two small pebbles together. Like the Skylark and House Sparrow, they both bathe in water, and dust their feathers in sand. Bechstein speaks of Mules between them and the Canary.

From the following account given by a correspondent, in a contemporary, it would appear that these birds were migratory in the northern parts of Europe. He writes, "A Norwegian brig put into Penzance a few days since; and among other incidents of the voyage between England and Norway, the master of the vessel mentioned that, midway between the two countries, thousands of small Sparrows passed and alighted on the ship, covering the deck, &c.; the birds were exhausted and soon died, and some half dozen were kept from mere curiosity to show to friends. These were brought for my inspection a day or two since by a person who begged them of the captain to show me. The six specimens were all *Passer montanus*, the Tree Sparrow, the Mountain Sparrow, of Bewick.—Edward H. Rodd, Penzance."—B. P. BRENT.

CURE FOR THE FILM ON GOLD FISH.

I PERCEIVE that some of your readers have experienced a difficulty in respect to their Gold and Silver Fish, and, therefore, forward you the following detail, as I know the remedy is both effective and inexpensive:—

Some thirty years back, a friend of mine, who then lived some three or four miles in the country, whilst I myself was at that time tied to the town, entered into a sort of co-partnership. He pos-

sessed a good-sized pond, and I found Gold and Silver Fish to stock it. As from a spring some little distance off it was supplied with a constant accession of fresh water, we were very sanguine of success with our pets, and for a year or so everything progressed most favourably; after that time, however, the Fish were troubled with a disease exactly resembling the complaints mentioned by your correspondents—a kind of mouldy-looking film came upon them in patches, which gradually progressed to the gills, and even extended itself over the eyes, causing partial blindness and eventually certain death.

With all the ardour of youth, we tried every possible appliance that friends suggested, but without any benefit whatever; and found, to our great annoyance, that every attempt at cleaning the fish by hand was only a brief addition to their sufferings, and death occurred in a day or two afterwards. We tried Perch in the same water, but they in a week or two became as infected as their more-brilliant-coloured companions. A gamekeeper of a friend of mine suggested, "That the sides of the pond were bricked, all the water was deep, and the bottom being muddy, the fish had no shallow scours to clean themselves upon, and they would never be better till they had." A place was cut out of the bank at his suggestion, some six yards square, the water covering it perchance a foot deep; the bottom, however, of this part was sharp grit, or drift sand, and small pebbles taken expressly for the purpose from the turnpike road. It was then summer time, and the fish of every kind at once commenced "cleaning themselves" by rubbing sideways over the bottom with the greatest diligence, and quickly recovered; nor did the disease again present itself. For many years afterwards they both grew and bred freely, until the pond was eventually filled up for building purposes.—EDWARD HEWITT, *Sparkbrook, Birmingham*.

DOES THE QUEEN BEE GOVERN THE COLONY?*

THE sovereignty of the queen bee has been long held to be the very model of a beneficent despotism, founded upon the highest principles of filial love and parental affection. For the first time, we believe, since the honey-bee attracted the notice of scientific observers, an enthusiastic apiarian has ventured to contravene the received opinion on this point, and actually to push matters to the republican extreme, of declaring the so-called queen "to be a creature of the colony, and subject to their power and control from the time the egg is deposited from which she is reared up to the perfect queen, and from that time to the day of her death." Most apiarians are aware of the stimulating influence of a good honey season on the breeding powers of the queen bee; but Mr. Harbison believes that "this matter is regulated entirely by the common worker bees, by the quantity or quality of food they give her; or, in other words, she is an instrument which they use as they see fit, to supply them with eggs, from which to replenish the hive with young workers."

Some writers on bees go so far as to imagine that nothing is done in or about the hive unless by orders emanating from the sovereign herself. To such Mr. Harbison replies, that when a queen is removed from a colony no disorganisation ensues; but that after a careful search for the lost one, the duties of the hive are carried on with the same order and precision as if a queen were present. "Now," he asks, "if the queen rules a colony and directs its movements, laying out all the plans, &c., as most writers would have us believe, where is the directing or governing power in the absence of the queen?"

We have ourselves recently witnessed an instance in which the workers summarily made away with their common mother. An artificial swarm appeared to take a dislike to the hive in which it had been placed and quitted it the next day. After rising in the air, they returned to the obnoxious hive without clustering, and shortly afterwards the queen (a very fertile Ligurian, with defective wings) was discovered on the ground in front of the hive. When placed on the alighting-board she was allowed to enter without opposition; but was found the next morning lying dead on the same spot whence she had been picked up the day previous. Supposing, therefore, the queen bee to be an absolute sovereign, her despotism, like that of the Czar of all the Russias, appears liable to be tempered by assassination.†

* *Bees and Bee-keeping*. By W. C. Harbison. New York: Saxton & Co.
† Since the above was written the artificial swarm has thrown off a swarm under a young queen. It is, therefore, more than probable that the queen regnant fell in combat with this young princess, instead of being put to death by the workers as at first supposed.

Mr. Harbison also asserts that "no eggs are deposited by the queen in queen cells," arguing that the hatred manifested by a queen regnant towards all embryo princesses proves "very conclusively that the queen of a colony does not desire any other queen raised in her domains for any purpose, and, consequently, does not deposit any eggs in the royal cells." His theory is that eggs are removed by the workers from common cells, and placed by them in the royal cradles. Without indorsing this opinion to its full extent, we may remark that we have known queen cells established on more than one occasion by bees in the absence of their queen, and tenanted by an egg which must have been brought from some other part of the hive, since we have been well assured that there was previously no egg on the spot where the cell was formed, or even in its immediate neighbourhood.—A DEVONSHIRE BEE-KEEPER.

VARIETIES.

PRODUCTIONS OF EASTERN AFRICA.—The climate of most of these countries is remarkably beautiful and healthy, the average temperature being 56° Fahr.—the highest 70°, and the lowest 46°. The Gallas occupy vast and noble plains, which are verdant almost all the year round, and afford nourishment to immense herds of cattle. Their houses or huts are round and cone-shaped, covered with roofs of grass, and mostly inclosed by a low stone wall for security against sudden attack. The villages or hamlets are for the most part in groves or woods, on heights, or on the sides of mountains and rivers. The land is rich in springs and brooks, well supplied by the tropical rains, which last for three months, besides which there is a second short rainy season. Wooded mountains and hills also abound, which serve for places of refuge to the inhabitants in time of war; and the tall Juniper is among the most remarkable of the trees which adorn these forests. The Gallas have priests, called Lubas, as distinguished from the Kalijās, who are their magicians, exorcists, and medicine men. As in the case of most heathens, so with these people, a tree has an important place in their religious ceremonies. Under the shadow of the Woda sacrifices and prayers are offered up; a higher spirit even is supposed to dwell within it, on which account the Woda is esteemed holy, and no one dare fell or harm it without losing his life. Of the greatest sanctity is the tree Worka (*Ficus sycamorus*), Woda Nabi, by the river Hawash, where the Gallas every year offer up a great sacrifice, and pray to their highest deity, Waka, sacrificing oxen and sheep to him, and drinking plenty of beer, and smoking tobacco. In their prayers, which have no fixed formula, they say, "O Wak, give us children, tobacco, corn, cows, oxen, and sheep! Preserve us from sickness, and help us to slay our enemies who make war upon us, the Sidama (Christians), and the Islama (Mohammedans)! O Wak, take us to thee! lead us into the garden: lead us not to Setani, and not into the fire!" On this occasion, the Lubas, or priests, augur from the entrails of goats whether victory or defeat is to accompany the Gallas in the coming year. From Magonbani I had to continue the ascent a league and a half, until I reached the village Jibana. The road was very steep and rough, and led through woods of Sumach, the Copal tree, which reached a height of from 60 feet to 70 feet, with thin and small leaves, and a white bark. I saw many trees with incisions in them made by the natives, that the sap might flow to the ground and crystallise by mixing with the earth, and the Mohammedans make yearly a great deal of money by this valuable varnish, which is sent to India and Europe. There are few wild beasts in these woods, but they abound with beautiful birds. There are said to be elephants in the Galla land, in the neighbourhood of Emberria; but in the Wanika territories there are no longer any of these animals to be found, as they recede more and more into the large forests, and to the rivers of the interior, owing to their being so much molested since European commerce with Zanzibar has produced so great a demand for ivory. If it be true that yearly about six thousand elephants' tusks are brought to the Snahili coast, it can easily be understood how quickly these animals diminish, and why they recede ever further into the interior of Africa.—(*Krafft's Travels in Eastern Africa.*)

PRODUCING DOUBLE FLOWERS.—The Germans, it is known, are very successful in growing seed of Asters, Stocks, and Balsams, that produce very double and beautiful flowers. This is done by growing the plants crowded in pots, in a very poor

soil, until the blossom-buds are forming, when they are liberally watered every day with rich liquid manure. The effect is a few fine seeds that will produce perfectly double flowers, instead of a great many poor seeds. Mr. James Eadie, in an essay read before the Progressive Gardeners' Society of Philadelphia, alluded to the fact in the following terms:—"Much depends upon the state of growth of the parent plants; if they are growing very luxuriantly previous to setting their seeds, the seedlings will prove strong growers; but if, on the contrary, the plants are weak, and when setting, and while maturing seed, are stimulated into a strong and vigorous growth, the fruit will be larger, and the tendency to produce double flowers very much increased. This is a fact well known to the German florists, who are proverbial for producing double Balsams, Asters, and Stockgilly flowers. It also explains the reason why the Dahlia and Hollyhock flowers remained so long single, although the plants were as strong growers then as now, and why their seedlings are so certain to degenerate, no matter how strong the plants are, unless every means are taken to stimulate them while setting and maturing seed. It may also explain why Tulips and Pansies are so generally produced single at this day, as any stimulus given to them while in flower causes the colours to run and intermix, thus spoiling their beauty in the eyes of critics, for any tendency to double flowers in these plants is accompanied by defective colouring. The best raiser of the Stockgilly that I ever knew, used to grow his plants in very small pots and poor soil, until the blossom-buds began to form; he then planted them out in a bed of rich soil, and supplied them liberally with manure water until the seeds were ripe, and from seeds so produced he had always a large proportion of plants that had double flowers, and the plants of a fine dwarf habit, which would not be the case when the stimulus was applied during all the period of growth."—(*Prairie Farmer.*)

EGGS.—The large number of 63,554,640 eggs were brought into this country in the four months ending April 30, 1861, being an increase of upwards of thirteen millions over the corresponding period in 1860.

OUR LETTER BOX.

DORKING CHICKENS AT CHESTERFIELD.—"I was much gratified by the flattering remarks on my Dorking chickens exhibited at Chesterfield, but I cannot claim the honour given me in your paper of taking prizes at Beverley, as I did not exhibit there this year. I think Mr. Berwick was there the successful exhibitor."—J. G. A. BAKER.

DORKING COCK WITH SWOLLEN FOOT (J. L.).—If there is not a thorn or piece of glass in the foot, it is probably bruised by flying down from a high perch. If the latter is the cause do not let the bird roost on a perch higher than a foot from the ground, and take care that he does not at any other time bring a heavy pressure on the foot by flying over palings, &c. We should confine him to an outhouse with the floor covered with sand, and to a grass-covered run. If a thorn or other sharp article is lodged in the foot this will not heal until that article is removed by means of a sharp penknife. Continue the bathing with hot water, and keep the bird chiefly on soft food.

RAPE SEEDLINGS (J. H.).—The green leaves of these raised from seed of what is popularly called "Bird Turnip" or "Summer Rape," are very good green food for Canaries, Linnets, and similar birds.

BEE-HIVES (Yorkshire).—We know of no place now where Mr. Payne's cottagers' hives and others can be obtained cheaply. If we wished, as you do, to introduce them among "our villagers," we should buy one of Messrs. Neighbour & Son, and with that as a pattern any country hive-maker could construct them.

BEES BY POST.—The five Lignian workers kindly sent by Mr. Woodbury were dead when they reached me. On attempting to resuscitate them, one made a last slight movement. Probably the appearance of the parcel had excited the curiosity of some post-office official, as both ends of the small pill-box containing the travellers were driven in.—WILLIAM EAGLESHAM, *Stewarton.*

LONDON MARKETS.—JUNE 10.

POULTRY.

The supply goes on increasing, and the demand is good, making trade far more pleasant than it was. There is not, perhaps, so much poultry as usual; but after the positive dearth we have had, the present supply seems very great.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 72.5° and 49.3° respectively. The greatest heat, 93°, occurred on the 22nd in 1846; and the lowest cold, 30°, on the 20th in 1855. During the period 130 days were fine, and on 108 rain fell.

CAUSE OF THE VARIATION OF FLOWERS.

OF Deal, states, and, apparently, he is corroborated by Mr. Lightbody, that when Auriculas throw up side blooms these keep pretty true to their character; but that when they throw up a heart bloom—that is, from the axis of the plant, the flower, no matter what may be the colour of its edging, “is just as likely to come in any other class as in the one it belongs to.” This seems to be an extremely curious observation.

It shows that some little light could be thrown on the laws of variation, if the many acute observers who read THE JOURNAL OF HORTICULTURE would contribute their knowledge on such points. I wish “D.” would have the kindness to give a few more details, such as out of so many heart blooms so many lost their character, and so many kept true; giving also the proportion in the side blooms which kept true.

As I am appealed to, I will make a few observations on this subject; but I have no doubt others could throw more light on the question. Professor Moquin-Tandon asserts, that with irregular flowers, as Snapdragons, the terminal flower in the axis of the plant is more apt to become regular, or peloric as botanists say, than the other flowers. I once found a Laburnum tree with the terminal flower on each raceme nearly regular, having lost its peablossom structure. With many Pelargoniums (I have one at present in my greenhouse, but I know not its name), the central flower in each truss every year comes regular, loses the two dark patches of colour on the two upper petals, and, what is very curious, loses the nectary, which may be seen in all the other flowers cohering to the flower-stalk. In the common Carrot the central floret in the umbel is dark purple and very different from the others; and I find that this central little flower is extremely variable. Are there not other cases of species which habitually have the central flower different from the others? It must, however, be confessed, that Mr. Masters, a high authority on such subjects, disputes that peloric flowers are apt to be central; but it seems to me extremely improbable that the several recorded cases should be due to chance, and all these facts seem to hang together and to indicate that in the flower nearest the axis there is a tendency to differ from the others, or to be variable, or to revert to a hypothetical regular form—that is, as I should look at it, to revert to the structure of a remote ancestor. The curious case of the Auricula apparently falls into this same group of facts.

I hope that some of your correspondents will state whether in the case of single buds sporting, as has so often occurred with Pelargoniums, it has been observed that such sports occur more frequently on one part of the plant than on another. I suppose it is not so, or it would have been noted. Having alluded to the central flower

in certain Pelargoniums which have lost the two dark patches of colour and the nectary, I would venture to ask some skilful observer to try whether this flower could be made by artificial fertilisation and by pulling off some of the adjoining flowers to yield seed. The stigma should be fertilised with pollen from, if possible, a peloric flower on another plant; and access of other pollen should, of course, be prevented. Peloric flowers have generally been found quite sterile; but Willdenow got seeds from a peloric Snapdragon, and the peculiarity was inherited: hence it is possible, though not probable, that a new strain of quite symmetrically-flowered Pelargoniums might be thus raised. Experiments are tedious and very often fail; but it would be well worth while for any man endowed with plenty of patience to collect seed from the central floret and from the other florets on the same truss of any ordinary Pelargonium, and sow them separately and see which varied most. Of course, all the flowers should be fertilised by the same pollen and subsequently protected from insects.

The same law which causes the heart bloom on an individual Auricula not to keep so true as a side bloom, might cause the seedlings of the central flower of a Pelargonium or other plant to vary more than the seedlings from the other and exterior flowers. This would be a secret worth discovering and revealing.—CHARLES DARWIN, *Down, Bromley, Kent.*

ARRANGING FLOWERS IN BOUQUETS AND VASES.

(Continued from page 192.)

MOUNTING AND MENDING.

ANOTHER useful though mechanical operation is that of mounting and mending flowers. Every one knows how often a beautiful flower-head falls from its stem, and how often we are forced to refrain from gathering one bright blossom, because on the same stalk are others not yet out which we cannot sacrifice.

The mounting prevents this difficulty; for a flower with less than half an inch of footstalk does quite as well for a bouquet as any other could do, taking it in its freshest state, either newly gathered or preserved in a dark cupboard (the cupboard must, however, be perfectly fresh and airy) and then pressing the smallest piece of well-soaked cotton wool around its stem. A little piece of wire wound upon it keeps the wool closely fastened on, and at the same time fixes the flower in its proper place. The cotton requires soaking and pressing together in the water for some time to become thoroughly saturated, unless a morsel for each flower is moistened separately. A fresh green Myrtle leaf does very nicely for rolling over the little piece of wool.

Many persons, including most of the French florists, have the habit of binding their flowers on little pieces of stick—common square bits of deal, for instance; and these are well adapted to the purpose, being so perfectly hard and light.

But special flowers have still their little peculiarities. A Rose, we will suppose, has snapped from the stem just underneath the cup. To bind the wire above the cup would be likely to cause the petals to be too much compressed or cut. It is better to take it round the calyx just where it is sufficiently compressible to give a secure hold; even carrying one sharp end of the wire through a needle-pierced hole rather than risking damaging the flower more, and then proceeding with it as I said before.

A white Camellia, again, is injured by the smallest touch of moisture on its petals, as it causes on them a yellow stain, quite destroying the fairness of that pure white flower. It needs very great care in its preparation, and does most beautifully then.

The best way is, before touching the flower, to moisten thoroughly a piece, the size of half a crown, of white cotton wool (using for pink flowers pink wool in preference). This should be laid on a larger piece nearly the size of the flower itself, which should then be most gently raised, two ends of a loop of wire having first been passed through the centre of the wool. Often, especially for an inexperienced hand, a piece of Berlin wool does better than the wire, as a too-tight pull would be likely to do less damage. An experienced flower-mounter would, however, in a moment, raise the enlarged loop to touch the lower petals evenly all round; cause it to slip between the leaflets, or points of the thickish calyx and the flower itself; tighten it almost imperceptibly, yet enough to retain its hold; and then, rapidly reversing the flower, or raising the wool to it, she would pass the wire through the wetted wool, bringing it down upon a support formed by a spray of Camellia leaves or a branch of stumpy foliage of some evergreen kind; or binding it down upon the piece of deal I spoke of, and arranging the wool to rest on the green foundation through which the stem formed passes.

Some persons use melted isinglass rather freely to cause the petals of the flower to adhere to the wool; and where the Camellia is to be worn in the dress or hair, this practice cannot be too strongly advocated. Besides the security as to keeping the flower moist, it insures some petals remaining on the wool, even supposing that the rest should fall.

In a beautiful crown of Camellias I remember being used in the adornment of a beautifully wreathed doorway, the flowers were arranged something in this manner. They were required to last for several days in the place they filled, and at the end of the third day they were still in perfect beauty. The blaze of light then caused these leaves to drop; but the wool underneath retained the appearance of the flowers still, as it would do always when the petals thus clung to it. The effect was so good that I had the curiosity to take very considerable trouble to ascertain the name of the maker of that crown, and to find out by divers experiments the process that had been used, which many times since has stood me in useful stead.

Clearness is a great benefit in any gum you use. Isinglass is so good from being so stiff and yet so sticky, while quite free from any yellow tinge.

Then, for mounting Geraniums, Azaleas, and so on, the heads are, properly speaking, cut off with an inch or so of stalk, a drop of gum given inside to fix the flower, and then the usual process is performed of rolling in wool and wiring.

Sometimes, however, there are single blossoms separated from the cluster to be grouped together. Attaching a short wire to the stalk of each, all may be duly twisted together and provided with the usual wool; and thus one often gets a few stray bunches of very well-looking flowers.

Lilies do most capitally treated like Camellias as to the bed of well-wetted wool on which they should repose; but little clustering flowers should always be fixed on

sprays of foliage similar to their own in growth; and they are, therefore, rather adapted for surrounding and softening the edge of the more solid circles, or for the circle of waving green and flowers that surrounds the whole.

The rule of affixing to each flower its own appropriate foliage is one that greatly deserves to be remembered well; each flower seeming to have some peculiar shade and shape of leaf which, beyond all others, suits it.

PASSION-FLOWER AND ROSE DESIGN.

I will give a plan this week for another drawing-room dish of flowers—one which might well appear on a dinner table also.

The flowers of the pale blue Passion-Flower, and of the very palest pink Rose that happens to be procurable, are those I want to recommend to-day.

The Roses are all the better if they are not very double. They should be nearly full blown, and will, therefore, require changing probably two or three times over before the beautiful, cool-looking, and sweetly scented blue flowers will begin to manifest any signs of withering.

The flowers being all very pale, I do not think that any deep green with them looks well. I prefer to any a pale colour just about the same depth as that of the flowers themselves—about what, in works shaded in sixes, would be called the third shade. They are, however, the only flowers I recollect just now which also look really beautiful when arranged together without any leaves at all. I believe, in reality, the pale soft tints do not require any great contrast to set them off, it being rather their own harmony on which they depend for beauty.

The loveliest way I ever saw them done was in a large raised crystal dish filled with water, and standing on a table; between the flowers was the clear cool water, looking so fresh, with the flowers seeming almost to float upon it.

The Passion-Flowers alone are very lovely; but if mixed with the Roses a double row of the latter all round the dish, fringed with a wreath of Fern leaves, and a group gathered loosely in the centre of the pale blue flowers, quite unmixed with any other colour, has a particularly delicate effect: the odour, too, is delightful. When they are to be really mingled I think green should be more made use of. Acacia leaves do well for the purpose, having the desirable very pale and yellowish-green tint.

In this case I should say that a ray-formed design was best; laying first the thick fringe of pale Acacia leaves all round the edge, then placing the Roses, and lastly putting in the Passion-Flowers to fill up the wedge-shaped spaces left.

This would be very beautiful, but not nearly equal, I think, to the loosely arranged group with its wide Rose-border. Some designers would even place a common tumbler in the middle of the dish; and after arranging the latter with its Rose wreath and a single band round the foot of the glass of Passion-Flowers, they would group together in the central tumbler a knot of drooping flowers; thus raising them a little that they may show the better their exquisite shape and colour while drooping over; the glass remaining hidden.—E.

(To be continued.)

OPENING OF THE ROYAL HORTICULTURAL SOCIETY'S GARDEN.

(Continued from page 197.)

I LEFT off at Mr. Warner's *Lælia purpurea* or *purpurata*; and there were only the small collections from the Continent, by Linden and Verschaffelt, to finish the front stages of new and rare sights. But having got hold of the button-hole of

Mr. Hill, of Keele Hall, our best Grape grower, and extracted some of his secrets, I shall tell of them first.

He agreed with me that all our best seedlings from the Dahlia up to the best Muscat Grape are so run upon in their properties by close propagation, that no mortal can bring them up to the starting-post for the first two or three years after they are "let out," much less have the chance of winning a prize with any one of them, save in some very rare instances. And he instanced his own Buckland Sweetwater Grape in corroboration of his theory of the chances and fate of new seedlings.

When I asked him how he managed to grow the bunches and berries to such enormous sizes, seeing that Mr. Ivery had but just sent it into the market, as it were, he told me the whole secret: his house of Black Hamburgs, or his plants of them, rather, are now in their prime mood, from eight to ten years of age, and as soon as he obtained the Buckland Sweetwater he grafted it on that plant of the Black Hamburg that never yet failed him in competition, and "the result is before you."

"But how and when did he graft?" In March, 1860, he grafted a shoot of the previous year's growth with *one bud and two inches of wood*. First, he cut off the top part of the yearly shoot of the Black Hamburg to a very firm-ripened part near the bottom, then split down the stump in the centre just through the pith part; the bud of the Buckland with the 2 inches of wood had 1 inch below the bud and 1 inch above it; the inch below the bud he made in the form of a wedge, and put the wedge "home" in the cut of the stock, so that the bud itself sat, as it were, on the top of the stump—a carpenter could perform the operation, and any gardener could clay the graft, and moss it too, and keep the moss between damp and wet till the eye was a shoot of 1 foot in length—then he would undo the clay, loosen the bandage, and tie again very loosely, and put some fresh moss over it, and keep it so to the end of August; but, of course, there would be no need to keep the moss and loose bandage on so long; only in an experiment with a very new or very rare Grape one often goes beyond security to make doubly sure. Mr. Hill grafted last spring twelve-months, and this June took a prize for it at the grandest Exhibition that ever was seen—just eighteen months after putting in the graft. And he told me he would serve Ingram's Prolific Muscat, the Trentham Black, and all new Grapes in future just as he did Ivery's Buckland Sweetwater.

I tasted Ingram's Prolific Muscat since, and tasted no other Grape that day before it, so that the flavour of one could not deceive me in another, and I can now say of it as I did of the Buckland Sweetwater, and with equal confidence in the result.

At present Mr. Hill is certain we have no better Vine for a stock to graft on than the Black Hamburg; but he thinks it very probable that some of the American Grapes which are more hardy will ultimately be found superior for amateurs and most gardeners to graft on. Until such time as these wild American Vines are tamed to graft upon, take short two-joint cuttings of Miller's Burgundy Grape, and, my word for it, you will have a much hardier stock than the Hamburg and a better one for ninety-nine growers out of a hundred. Plant lots of such cuttings round the walls or palings about the garden from October to February, and if you should never want them no harm will be done. Then six or seven little gardeners might club together, and buy one thumping good plant of any new Grape the very first season, divide the buds at the end of March, and each graft his share of the buds on his own Vine-stocks, and perhaps some of them take a prize for Grapes before persons in their condition of life could even think of buying the plant to try.

There is little fear but the fruit stages in future will be placed against the back wall of the arcades; then as many of the pot Vines as possible ought to be trained against the back wall as Sir H. Meux's gardener did four of his pot Vines that day. I heard a great deal since about the effect of these Vines so trained.

Now we take up the thread of the front stages in M. Linden's small contribution, consisting of *Dichorisandra albo-marginata*, a little different from the leaf of *thyrsiflora*; *Echites argyræa*, a pretty-leaved climber; and some nice little Ferns. Over them was hanging down in fine bloom the smallest-stemmed and one of the most graceful Indian Dendrobes—namely, *D. Falconeri*, but by whom it would be difficult to say.

M. Verschaffelt followed with a *Coleus*, named after himself; but I would seriously urge on him not to have plants so named for the English market, as we cannot pronounce that kind of foreign botany like the Russians and Cossacks. *Dianthus* the same unpronounceable name; a *Campylobotrys*, with a tenfold objectionable and unpronounceable name. If we do not set our faces firm as brass against this style of continental invasion with hard names we must have an extension of pages to take them in. There were, also, *Begonias* and *Cycladias*, but these are now too much overdone, as Ferns have been lately; but there is plenty of room for grand selections in Ferns, and in most plants of great families without hunting out every spot and speck on the rib of a leaf to the third and fourth degrees for the sake of a difference.

Botanical rarities are out of place at exhibitions, collections the same. A careful selection is the grand secret, and should be the aim of all who want to make an impression on the public mind; and here is a selection of *Begonias* by the Messrs. Veitch, the only ones of which I took the names. They were in rows across three steps or stages, three in a row, and this is how they were staged—Marshallia, Nebulosa, and Queen Victoria, one row; President, Vanden Hecke, Duchesse de Brabant, and Eekhaute, next; Count Alfred de Limmingi, Princess Charlotte, and Isis. In front of these stood a lot of seedling *Begonias* down on the path, no one being there, probably, to look after them. Lady Cullum was marked on one, so it must have been from Suffolk, perhaps from Mr. Fish, her ladyship's gardener; but I could see no more names.

Orchids followed, but were not much different from those seen lately at the Crystal Palace. Mr. Stone was first again, and had different. *Erides Lindleyana*, *Cattleya Wagneri*, a fine *Cymbidium eburneum* (a fine thing). *Erides Larpentæ* and his *Cattleya Aucklandiæ* had four blooms on, the largest number I ever saw on one plant open all at the same time, and a little plant of *Barkeria spectabilis*.

Next lot of twenty plants had nothing striking; but in the next class of sixteen plants Messrs. Veitch came out strong, and in their peculiarly good style of growth. *Oncidium Lanceanum*, grown as I never saw it exhibited, just up on a dry, branching block. The *Phalanopsis* in this lot were the most splendid ever seen; but they were all extra. Mr. Woolly followed with *Dendrobium Farmeri*, *limbriatum*, and *densiflorum*, as his best. Mr. Rhodes next with one open butterfly bloom (*Oncidium papilio*), and the pretty *Dendrobium Devonianum*.

The collections of stove and greenhouse plants I never saw placed with better effect, and they never looked so well in any other way I had seen them. As to the kinds and names, one could tell them without ever seeing the show at all, as they are always the same names over again; but some of the plants were extra there, as the *Ixora salicifolia*, in Mr. May's first-prize collection; also his two red *Pimeleas*, *mirabilis* and *Hendersoni*, two very much alike, and too difficult to grow for many to try. I said of Mr. Chilman's *Acrophyllum*, that it was the best specimen of high gardening at the Show in the style of specimen plants.

The *Azaleas* did not tell nearly so well there as at the Crystal Palace. They were too crowded for one thing, but the plants were, many of them, the same. The great battle of the day between monster specimen makers lay between the Messrs. Veitch and Mr. Williams, of the Paradise Nursery, in their specimen Ferns; and here the Messrs. Veitch were most handsomely and very completely beaten for the first time in my notes. Mr. Williams' Ferns (and he had all the *Gleichenias*) measured from 4 feet by 4 feet to 8 feet by 8 feet, that being the extent of his *Gleichenia microphylla*, and he had them in two-foot or three-foot-square boxes, enough for four men to lift on a truck.

A fine specimen plant of *Rhododendron Maddeni*, from Mr. Jackson, deserves special notice, in full bloom, and growing as close as a ponticum. In the race for the best new *Azaleas* since 1856, Mr. Turner took the first prize, and Mr. Ivery again was the only one to compete with him. The quantity of bloom in the former seemed to sway the Judges more than the sorts; but here they are. Mr. Ivery had *Etoile de Gaud*, *Harlequin*, *Model*, *Baron de Vriere*, *Empress Eugenie*, *Flower of the Day*, and *Baron de Pret*, *variegata superba* and *Kinghorni*. Mr. Turner's were—*General Williams*, *Model*, *Duke of Cambridge*, *Prince Jerome*, *Standard of Perfection*, *Queen Victoria*, *Magnet*, *Milou*, and *General Havelock*. These comprise the very cream of the new *Azaleas*.

In the west arcades Messrs. Veitch had the best six kinds of Dracenas, and the Messrs. Lee next. Both had the fine new *Dracena indurata*. Here, also, the Heaths had the best pull. Mr. Peed, who was first, had fine plants of such Heaths as *depressa*, *Massonii*, *eximia superba*, *mirabilis*, *Beaumontiana*, and *obliqua*. Mr. Jackson next, with *Bergiana*, *Humeana*, *depressa*, *Cavendishii*, and *ventricosa superba*; and here, too, Mr. Standish stood second in *Rhododendrons*, Mr. Noble being first in them at the east-end arcades.

Here, likewise, were two collections of immense Ferns, *Gleichenia microphylla* again being the very best of them all in Mr. Baillie's collection, which stood second best, while Mr. Stone was at the top.

At the extreme east stood two large pans of *Disa grandiflora* from the top of Table Mountain behind Cape Town, from Mr. Leach, the greatest effort of prize gardening of all that were at this Show. No one in Britain having yet succeeded in growing this plant to perfection, except Mr. Leach himself, and he says it is as easy as any other plant when the right treatment is given—say a mountain plant from a bog quite as hardy as any of the old Cape Geraniums. He had it out of doors under a hand-light all last autumn, and no plants were ever more healthy or free-looking in their growth. I have patronised this plant from the first to test the skill and patience of our craft; and now I am happy to be able to record that all the difficulties have been entirely got rid of, and that a score of healthy plants of it will soon be ready for twenty of our prize-taking gardeners to begin with, and that Mr. Leach very kindly offers them to any of our enterprising dealers on condition that the proceeds of their sale may be given to the funds of the Gardeners' Benevolent Institution, and surely there will be no lack of gardeners' friends to undertake the benevolent task. The plants will be ready in a few weeks, and application meantime may be made to C. Leach, Esq., Clapham Park.

Another scarce plant was a *Sarracenia flava* with twenty-two leaves, and each leaf ending in a pitcher, from Mr. Barnes, gardener to W. S. Nichols, Esq., Bowden, Cheshire, a fine-done thing certainly; and I see the dwarf dark purple *Narsturtium* I mentioned last week as likely to be a good or best bedder of that race of *Tropeolums*, was from an old Suffolk man—Mr. Coates, now of Brixton. Good luck to him for this contribution to our bedders.

Mr. Turner had here other bedders, *Herald of Spring*, a large, light, Scarlet Geranium; also, *Rose Celestial* (Sanky), in the caste of Rubens, and very promising, and his new Prince of Hesse, the best of the Kingsbury Pet family. Among tall Caeti were four good seedlings from Mr. Robinson, gardener to R. Beynon, Esq., Reading, or near it, of which *Gloriosa florbunda* was the best; *Aurora borealis* and *Hoylei* next, and all with the exquisite flush of *speciosissimus* conspicuous upon them, the plants being like Ackermans.

And now for the 89 yards of variegated and fine-leaved plants in one bank—the finest sight that ever was seen of such subjects; but I was all along here in advance of the Judges, and at that point the French ex-Royal Family came there; and as far as I could make out from their gestures we were one on the merits of the great varied bank, however we may have differed from the Judges, who must have scrutinised the collections more than visitors and fly birds who tell tales and send them to the ends of the earth. Oddly enough the top plants were at the bottom of this bank—twelve splendid stretchers from the Messrs. Veitch. Here they and Mr. Williams were again face to face in fierce combat; and as the champions of the day they began with *Sansiviera zelanica*, 5 feet across; a splendid *Theophrasta imperialis*; *Pandanus javanicus variegatus*, 15 feet through or more, if the leaves were held up and stretched; *Bromelia sceptrata*, the fiercest looking, if not the father of all the Pine Apples; *Cycas revoluta* and other huge Palms; and a *Cyanophyllum magnificum*, with three branchy tops, and up to 8 feet or 9 feet or more.

To these Mr. Williams opposed *Dien edule*, 12 feet across, the most perfect specimen ever staged, and, probably, the most useful to those Mexicans who live on the fruit of it; *Nepenthes lavis*, very large; *Aralia Sieboldi* and *Cyanophyllum magnificum*, over 10 feet in height.

Between the combatants stood Mr. Cutbush, of Highgate, with his peaceful dozen, of which *Marattia eicutafolia* was the best. Then follows Mr. Sims, of Foot's Cray, Kent, with twelve magnificent Ferns in huge tubs, and here again the lovely *Gleichenias* were in the first rank of merit; also, an

immense *Dicksonia antarctica* and *Cibotium Schröderi*, *Cyathea dealbata* and elegans, and *Dicksonia culcata*. He must have a Crystal Palace to keep such plants. Then Messrs. Milne & Co., whose best variegated were *Caladium argyrites* and *Begonia Marshallii*. The Messrs. Lee followed with a fine *Alocasia*, *Cyanophyllum*, *Platyserium grande*, their fine *Cordylines*, variegated *Yuccas*, *Caladiums*, *Ropalas*, and a gigantic Lily, but only to be seen. Then Mr. Hedge, nurseryman, Norwich, the best of whose dozen was a *Cissus* and the variegated *Pandanus*. Mr. Jackson came in here with very large and most splendid specimens, as *Aspidistra lurida*, the best lurid in England; a *Dien* not quite so big as Mr. Williams'; the rare-to-be-seen *Heliconia metallica*; *Monstera deliciosa*, much more cut and slashed on the edges than *Monstera pertusum*, *alias* *Philodendron pertusum*, *alias* *persutum*, *Caladium seguinum*, very large; *Phœnix humilis*, *Livistonia Borbonica* and *Cerypha australis*, three Palms which are wintered yearly in a house with *Camellias*, *Azaleas*, *Dicksonia antarctica*, and a fine *Croton variegatum*. Mr. Gunner, gardener to W. F. Woolly, Esq., Kensington, next, with a seven-foot or eight-foot-stemmed tree Fern, *Dicksonia antarctica*, and *Ropala corcoradensis* as his biggest.

Then tens began with Mr. Robinson, who had a *Cyanophyllum*, with four branches at the top, and, by the way, when *Cyanophyllum* begins to branch, or is allowed to do so, the second name is gone—the magnificum is out of it then. A clean, clear stem of from 7 feet to 10 feet, and all the leaves as perfect and as clean and fresh-looking as the last leaf, is the only condition in which *Cyanophyllum* can be classed as a magnificent toy; and I was pleased to find the Judges, who pressed hard on my heels here, were of the same opinion.

The next ten from Cheltenham. Mr. Hamilton, gardener to F. P. W. Butt, Esq., an immense screw Pine, *Pandanus utile*, and a most beautiful-leaved *Cupania filicifolia*, were his dons, most different. The next ten from Miss Burdett Coutts' garden much the same as at the Crystal Palace. Next, Mr. Nicholson, gardener to S. Majoribanks, Esq., small, but well-grown stuff, of which *Caladium argyrites* and *Pteris argyrea* were the best or prettiest. Here Mr. Bowman, gardener to G. Hooker, Esq., in his collection of ten took the shine out of the nurserymen and all other gardeners with the most perfect specimen of *Cyanophyllum magnificum* that is under cultivation under the sun. Such a plant was never seen before; it stood 10 feet or 12 feet in height, and the lowest leaf falling over the pot was as fresh as the top one. Mr. Bowman and his employer will excuse me for saying how wrong it is to label the names for a public exhibition on fancy cards.

Mr. Young, gardener to Mr. Barclay, of Highgate, was next; and *Canna discolor* was different from the above; and Mr. George Young, gardener to W. H. Stone, Esq., Dulwich, followed. His two *Theophrastas*, *imperialis* and *macrophylla*, and *Aralia Sieboldi* and *reticulata*, were his best and most different.

Mr. Paget, gardener to J. S. Craigie, Esq., Chigwell, Essex, had one plant different from all the rest—*Hippomane longifolia*, 10 feet or 12 feet high, with rough long leaves like those of the *Loquat*, and spined like a *Holly*, and a drop of its juice might kill the strongest man in Essex, these *Hippomanes* being deadly poison among *Spurge-worts*.

D. BEATON.

HOW TO FLOWER CALLA ETHIOPICA BY CHRISTMAS.—Bring your plants to rest in midsummer, by exposing them to the full sun in a place where they are sheltered from rain. Do not water them. Middle or end of August take them out of pots; clean the rootstock from all decayed matter and from young accretions; repot in good, fertile soil, rather heavy, but part sandy; water and expose them to the sun in the open air. Water freely till the season compels you to house them. Take some to the warm house; put them in a sunny place very near the glass and they will remain compact. Getting stalky spoils their beauty. The more they get isolated in the summer, nay, the more they get wasted, the sooner will they flower in the warm house. Now take other plants which you housed in the greenhouse to the warm house, and you get a constant succession of flowering plants. Carry back to the greenhouse those which have flowered, and they will flower again at the general period of vegetation in the spring; often they will even flower a third time. The sun not only elicits plenty of flowers, but is a most

necessary agent in opening them. That accounts for stillborn flowers in sunless places. — (W. SCHOENBORN, in *Deutsches Magazin*.)

ROYAL HORTICULTURAL SOCIETY.

JUNE 11TH.

FLORAL COMMITTEE.—Probably the fact of this being only the day previous to the great June Show of the Royal Botanic Society militated against the production of many novelties. But whether it were the cause or not, the fact remains the same; for, save the remarkable collection sent home by Mr. R. Fortune, there was, comparatively speaking, nothing shown.

Mr. Veitch, of Chelsea, sent two *Fuchsias* with white corollas—one of somewhat elegant and free habit, called *elegans flore pleno*, the corolla being double or semi-double; the other *elegans alba*; but neither of them was considered deserving of mention. Also a very brilliant-coloured spotted *Pelargonium*, called Topping's Lady Churston; the colour deep orange scarlet with intense black spot. It seemed as if from one of the French varieties crossed with something of the old Victory strain; and, although defective in shape, it received a Label of Commendation as a useful decorative plant.

Mr. B. R. Cant, of Colchester, sent some blooms of a magnificent Tea Rose, which he stated he had under the name of *Aurora*, but which had been lost to the public, and which he proposed sending out again. The Committee entertained a very high opinion of it, but wished to compare it with another Rose of the same class, which it was supposed to resemble, before deciding on it. It was, therefore, reserved for next Meeting.

Mr. W. Paul, of Waltham Cross, sent a seedling Rose raised from Jules Margottin, of good properties and vigorous habit, of a bright rosy crimson shade of colour, good shape, cupped, and of good substance of petal. He proposed to call it *Beauty of Waltham Cross*. For this a First-class Certificate was awarded.

Mr. Melville, of Dalmeny Park, sent *Nemophila discoidalis* and two *Tropaeolums*; but they were not considered deserving of notice. There were also some seedling *Pelargoniums* from Bodmin and Pansies from somewhere else, of which we can only charitably hope the senders had seen nothing of the advance in either flower for the last twelve or fourteen years.

Mr. Standish, of Bagshot, contributed the collection of Japanese plants, sent home by Mr. Fortune, and several of which had already received the Medal of the Society. Those thus rewarded did not come under the notice of the Committee. Of the remainder, *Podocarpus microphyllus foliis variegatis*, received a Label of Commendation.

A First-class Certificate was awarded to a very pretty Holly-like shrub of very dwarf habit, *Osmanthus aquifolius nanus foliis variegatis*. A variegated variety of *Illicium floridanum*, received a Label of Commendation; and a First-class Certificate was given to a highly ornamental species of *Eurya*, broad-leaved, the young leaves of which were beautifully marked with gold and red stripes. These were all fully described by Mr. Beaton, in the report of the Horticultural Society's opening Show, where they were exhibited, so that it is needless further to allude to them; and with some *Gloxinias* from the Society's Gardens, comprised all the subjects exhibited.—D., Deal.

FRUIT COMMITTEE.—A Meeting of this Committee was held on Tuesday, June 11th, Mr. Charles Edmonds in the chair.

Mr. Standish, of Bagshot, exhibited three large and handsome bunches of Ingram's Hardy Prolific Muscat Grape; they were well shouldered, and the berries were of good size, of a deep black colour, and with a fine thick bloom; the flavour also was excellent. From the fine condition of the fruit, and the high opinion that was expressed at former Meetings upon the merits of this variety, the Committee awarded to it the special prize of £5, placed at the disposal of the Committee by Mr. W. Wilson Saunders. Mr. Standish also exhibited very fine bunches of white Frontignan Grapes, and four handsome Vines in pots, the latter of which were awarded a Certificate of Commendation.

The Prince Consort, President of the Society, sent a dish of very fine fruit of the Mango; these were large, oval, and somewhat flattened on the sides, the flesh was thick, very juicy, and richly flavoured.

Francis Darwin, Esq., of Kirkhill Hall, near Ottery, presented a collection of forty-nine sorts of Kidney Beans, collected in Madeira, all of which have been sown in the Garden.

ARE LARKFIELD RIVAL AND VIRGINEUM THE SAME VARIETIES?

In the autumn of 1858 or the spring of 1859 a Mr. Davies sent out a new seedling forcing *Geranium* called "Larkfield Rival." Allow me to call your attention to the two *Geraniums* here sent. A friend of mine, of much greater experience and longer practice, assures me that he has known *Virgineum* for near twenty years. Well, where is the difference? It is too bad. Florists should not "diddle" us like this. I know we are almost prepared to swallow anything; but—"burnt bairns fear the fire"—we shall get suspicious, and then will come a day of retribution.—NATHAN H. POWNALL, Gardener to Wm. Sanday, Esq., Holme Pierrepont, Nottingham.

[The specimens sent were certainly identical in truss, petal, and leaf.—EDS. J. H.]

NEW AND RARE PLANTS.

AMOMUM CLUSII (*Clusius's*, or *Golden-flowered Grain of Paradise*).

Nat. Ord., Zinziberaceæ. *Lin.*, Monandria Monogynia. Native of the west coast of Africa, Fernando Po. &c. It blossoms in December. Flowers bright yellow.—(*Bol. Magazine*, t. 5250).

STREPTOCARPUS SAUNDERSII (*Mr. Saunders's Streptocarpus*).

Nat. Ord., Cyrtandraceæ. *Lin.*, Diandria Monogynia. Native of Natal. "May, perhaps, bear the temperature of a warm greenhouse in summer. Its great charms are its size, the rich purple rose colour of the under side of the foliage, and the delicate greyish-blue of the numerous flowers, three plants in one pot producing at one time one hundred and twenty-five." It commences blooming in April.—(*Ibid.*, t. 5251.)

DIMORPHOTHECA GRAMINIFOLIA (*Grass-leaved Dimorphothea*).

Nat. Ord., Compositæ. *Lin.*, Syngenesia Polygamia-necessaria. It has also been called *Calendula graminifolia*, *Aretotis tenuifolia*, and *Bellis africana*, being "The African Daisy" of our forefathers. It was brought to Holland from the Cape as long since as 1698; and we quite agree with Dr. Martyn, who said fifty years ago, "Though it has been long in the English gardens, yet it is not so commonly seen there as it deserves, there being few plants which continue so long in flower." It begins blooming in April, and continues to do so, though not so abundantly, until late in autumn. The flowers within side are white, with a purple centre, and a coppery purple outside. They are of the size of the common *Marigold*. It may be raised both from seeds and cuttings. Sir W. Hooker says, "It might make a good summer bedding plant if the stems were pegged down."—(*Ibid.*, t. 5252.)

STENOCASTER CONCINNA (*Neat Stenogaster*).

Nat. Ord., Cyrtandraceæ. *Lin.*, Didynamia Angiospermia. "This pretty little plant flowered in Messrs. Veitch & Son's Nursery at Chelsea, in April last, but it is not known from what country it came, nor by whom it was imported." Flowers white, tinted with pale lilac.—(*Ibid.*, t. 5253.)

BEGONIA PHYLLOMANIACA (*Proliferous-stemmed Begonia*).

It has, with the same specific name, been included in the genus *Knesbeckia*. *Nat. Ord.*, Begoniaceæ. *Lin.*, Monœcia Polyandria. Its native country is not known. Its flowers are very pale pink, but neither they nor the leaves are particularly conspicuous. Its "extraordinary peculiarity is, that it produces from the stem, branches and petioles, innumerable leaflets, which, on being detached and placed on moist soil, produce roots and become plants."—(*Ibid.*, t. 5254.)

SEED-DRILL.—A very simple, and at the same time a very expeditious and effective mode of planting small seeds, is to put them in a wine-bottle, with a quill inserted in the cork, as shown in the cut. If the seeds are extremely small, and it is necessary to sow them thinly, mix the seed with dry sand before it is put in the bottle.

SPUR *versus* LONG-ROD SYSTEM OF VINE PRUNING.

Is it true that larger and much finer bunches of Grapes can be obtained by pruning the Vine on the long-rod system than on the spur system? and is not the long-rod system of pruning much more simple than the spur, and have not the Vines a much neater appearance? Also, can as great a number of bunches be grown on a Vine by the long-rod system as on the spur system? How many feet long will a rod grow in one season, being pruned on the long-rod system? Does a Vine require more nutriment when pruned on the long-rod system, on account of its having to support a growing rod as well as a crop of fruit, or not? And why, if the long-rod system produces larger bunches, is the spur system of pruning more generally adopted? On which system of pruning are those large bunches of prize Grapes one sees in Covent Garden produced?

Which gives the finest fruit and the largest quantity—a tree grown as a pyramid or as a bush in an orchard-house, of course both being in the same size pots?

Can hot air be introduced both under the borders and above, at the same time, into a house heated by the Kiddean system? And can a great amount of heat be introduced into a house by the Kiddean system?—*HESPERTS.*

[We do not think there is anything at all satisfactorily established as to the superiority of the long-rod system in producing larger bunches than the spur system, if quantity and quality are taken into consideration; nor do we think such a fact is likely to be easily established—inasmuch as a fruitful healthy Vine can only carry and ripen to perfection bunches in proportion to the space occupied by the roots in the ground, and the foliage in the atmosphere of the house fully exposed to light. Every well-ripened bud will then produce fruit, whether that bud be on a short spur or on a long rod. This fact lies at the foundation of rightly pruning many climbers and creepers as well as Vines. If the wood is not well-ripened the previous season, prune how you will, the flowers and fruit will not come. If the plant is growing extra vigorously, and the roots are getting beyond much atmospheric influence, there will be an advantage of the long-rod system, inasmuch as one shoot in summer would be able to get its leaves more fully exposed to the sun than leaves from a multitude of shoots, and consequently the wood would be harder and the buds more matured than when the same thing had to be done with a number of shoots: hence, in such circumstances, Vines will bear well on the long-rod system, when, without considerable care in pruning in summer and disbudding, they would not yield so well on the spur system. One reason is, that on the rod, when well exposed and allowed a fair amount of room—after a few small buds near the base, which will generally be barren in the following year, the other buds in the axils of the leaves will be pretty regular as to plumpness; and all these, or what is deemed necessary, will be retained: for when practising that mode we used to thin out fully the half of the buds in the winter pruning, leaving them regularly on the shoot; whilst, by cutting close back to a single or to two buds on the spur system, the largest and best-swelled buds are all cut away. When the roots, however, are all right, in a healthy Vine this is of little consequence, as the whole plant is so well matured and so stored with fruitful juices, that it is next to impossible to prune wrong. Even in a healthy Vine, and the roots near enough the surface to make it fruitful, we consider that very large bunches can only be obtained by leaving few of them; and on the whole, our experience and observation would lead us to give the preference for this purpose to long-rod instead of spurs, and thinning out the buds well before starting into growth. Here, however, in the way of caution, we must just notice another supposed fact in the way of observation—and that is, that though bunches on long rods generally show stronger at first than those on spurs, the latter generally swell and round off better at last. This may be owing to the sap flowing more freely in the young shoot in spring, and also to the larger surface of the old stem in spur pruning, which, though a little more languid in spring, supplies a larger surface for the young shoots to draw upon in autumn. This, however, may be deemed anything but orthodox; though in many instances we have noticed the fact, that though the long-rod shows the best, the spur mode often matures the best; but in practice as respects bunches, there is but little to draw between them. If there had, our best gardeners would not have given such countenance to the spur system.

Instead of agreeing with our correspondent as to the simplicity and neatness of the rod system, we would undoubtedly ascribe these advantages to the spur mode, unless in some very small house or pit, or on a wall not more than 4 feet or 5 feet in height. In such circumstances, treating the Vine as we do a Raspberry stool, would, in many cases, be best—leaving one bearing-shoot, selecting a cane for summer growth and removing all others, and cutting out the bearing-shoot of this year as soon as the fruit was gathered, and giving all the room and light possible for the shoot of the following year. Once establish a Vine on the spur system, and what can be simpler? The shoots are supplied on each side from the spurs. Laterals are duly regulated merely to promote root action, and removed when maturing, and not growing, is the object; and in the autumn and winter the shoots are cut back to a bud, to furnish the bearing-shoot for the succeeding season. When the main stem gets too old, or some of the spurs begin to fail, it is easy to renew it by training up a young shoot from the bottom; and, as it grows, the laterals on the bearing-spurs may be mostly renewed, which will give more room to the young shoot, and the free growth of this shoot will keep up a brisk root action. A similar mode must be adopted in a regular rod system; but then it is not so simple as mere spur pruning. The rod this season, with its side-bearing shoots, must be attended to; a young shoot from the base must be selected for next year, and as it grows its laterals must be stopped, all the laterals in the side fruit-bearing shoots must be removed, and even barren side shoots, as the young main shoot for next year reaches them. There will be the care required, that the point of this young shoot shall not be injured; for, if so, the upper part, though it breaks again, will be weaker than the lower; and if all this is guarded against, and a nice shoot some 15 feet or 20 feet in length is procured and well ripened in the autumn, and left to take all the growth next year, the fruiting-shoot of this year being removed as soon as the fruit is gathered—there is then the care and trouble to get this shoot to break its buds regularly all its length, which, if in a house, and especially if forced early, it will not, if left alone, be inclined to do naturally, but the highest buds will have a tendency to break first and take the lead; so that, to make sure, the shoots should be laid horizontally, or perhaps twisted a little to make the breaking regular. Out of doors, as in a late house, these precautions would not be so necessary; but all these little securities for regular breaking and attention in training are so many drawbacks from simplicity and neatness.

These things attended to, however, we do not think there is a pin to choose upon between the two systems, as to the number of bunches that may be grown, or as to the nutriment the plants will require. When either is duly carried out, there is not much difference in the long run as to the amount of foliage the Vines carry. In spur pruning, room must be found for laterals at first. In the long-rod the laterals on the bearing side shoots may be gradually renewed, as the young stem for next year takes the running.

The shade given, however, will be rather more on the rod system than in spur pruning; and the latter is, therefore, best fitted for a greenhouse vine, in which so many of our friends contrive to grow many plants and yet get good Grapes in autumn.

In a vigorous, healthy Vine there is hardly any bounds to the length a Vine shoot will grow in the season. We have had them grow from the bottom to the top of the house, and extend along the back wall to a distance of 40 feet or 50 feet in all; but such a length is anything but desirable. From 12 feet to 20 feet ought to be considered the longest length for a well-ripened matured shoot in one year; and, if extra strong, it is better to encourage side laterals at first instead of greater lengths, these laterals being removed gradually as the wood begins to ripen. When the length of a rafter exceeds 20 feet it will, in general, be better to have two rods in the length of the house; and, in this case, the shoot would be cut out every two years instead of every year.

We have known splendid fruit grown on the young shoots that adorned exhibition tables, and Covent Garden likewise; but we have also known so many fine bunches produced on spurs that we cannot answer our correspondent's question satisfactorily; perhaps some one now more intimate with Covent Garden will supply our deficiency. Meanwhile, let us observe that if splendid bunches above all things are desired, care must be taken to have few of them. The large-bunch system will not suit when a bunch

or two a-day are wanted for the table, and but little space to grow them in.

PIRAMIDS *versus* BUSHES IN ORCHARD-HOUSE.

The question as to quantity and quality of trees grown on these modes in an orchard-house, and in similar sized pots, is hardly a fair one, unless space was also taken into consideration. Trees in the same sized pots may be equally fruitful, though the plants in one pot be double the size of the other; and, to be equally profitable, should carry nearly double the quantity of fruit. Trees may be so nipped in as to bear from the pot to the top, rising up almost as straight and round as a gun-barrel, and scarcely wider at any part than the diameter of the pot. More of such plants can stand and receive light and sun on all sides, in the same space, than pyramids with a wide base and tapering upwards to the point, and more of the latter can be accommodated than flat-headed wide bushes. All the modes will yield good fruit in proportion to the sun and air they receive. In proportion to the mere size of the pot, without taking space into consideration, we would place the bush first as to quantity; the wide-based pyramid second; and the tall, upright, narrow pyramid third. But taking space and quality as the first considerations, we would place the upright pyramid first; the wide-based pyramid second, but first for beauty and neatness; and for all these united, the bush form third.

KIDDEAN HEATING.

We presume it will be as easy to heat the space under the border as above it by the Kiddean or any other system, provided the source of heat is placed sufficiently low that in either case the heat will be able to ascend. In heating from a chamber, it would be as well to have separate openings for the bottom and top heat. Whatever your mode of heating—furnace, flue, hot-air chamber, or hot water—there will be no difficulty if the source of heat is lower than the place to be heated.—R. FISH.]

CULTURE OF THE GRAPE VINE.

(Continued from page 177.)

CULTIVATION IN A GREENHOUSE.

THE kinds best adapted for a greenhouse are Black Hamburgh, Lady Down's, a Grape that keeps well, West's St. Peter's, Royal Muscadine, Golden Hamburgh, and Dutch Sweetwater. More kinds might he tried, but the above are good croppers and sure to answer.

PLANTING.—The best season is March, just before the buds break.

PRUNING.—The best mode of pruning for a greenhouse is undoubtedly the spur system; and for this reason, that the foliage is less in quantity, and, therefore, does not shade so much the plants that are in the house than when the single-rod system is adopted.

The *Pruning in Summer* consists in stopping the laterals at the third or fourth joint, and, when the side eyes burst, to stop these again and again throughout the growing season. Every fruit-bearing shoot should be stopped at the second joint above the bunch. When the fruit begins to colour, the first-made laterals should be cut clean off, in order to give more light to the leaves and fruit.

Autumn Pruning.—The Vines in autumn may be half-pruned by cutting off all the laterals in order to ripen the wood and fill the buds with fruit-bearing sap. As the leaves turn yellow they should be removed.

Winter Pruning.—This may be done in any of the winter months after the fruit is all gathered and the leaves all fallen off. At that season the greenhouse plants will all be housed. I always found it more convenient to prune the Vines by loosening them from the rafters in succession, bringing each one down into the walk or path, commencing at one end, it is no matter which, pruning each side shoot to one eye as directed before, and when that Vine was pruned, clearing away the loose bark and applying a paint made of water thickened with sulphur and clay. Use a softish brush and see that every part is covered with the sulphur. This mixture is a great preventive, if not a cure, for mildew, and destroys scale and red spider. Then tie the Vines down to the front in a bundle. In that position they may remain till the buds begin to break. By being thus trained horizontally at the lowest part, and consequently the coolest part of the house,

every bud will be in an equal temperature, and will all receive an equal amount of stimulating sap: hence the lower part of the rafter will be as well furnished with fruit as the highest, and the berries will swell almost equally as fine as those on the higher part of the house.

Spring Management.—I have often allowed them to remain in this horizontal position till I could stop the laterals, but when I did so I was obliged to be very careful of the young shoots, for in their young state they are easily slipped off at the base. There is, however, a great convenience in doing this work when the Vines are so handy and easily examined. As soon as one Vine was operated upon—that is, the superfluous shoots rubbed off, the fruit-bearing spurs stopped, and, if long enough, tied slightly to the main stem—that Vine was tied up to its proper rafter, and the next taken in hand, and the same operations gone through till every Vine was done. It requires at least two persons to do this; one to hold the Vine, and the other (the more experienced hand, of course) to thin out the shoots and stop those that are left. In lofty greenhouses crowded with plants, this spring dressing when the Vines are tied up to the rafters before it is done is a very difficult and troublesome affair. I therefore recommend the leaving them tied down to the front till they have made such a growth as will enable the cultivator to give them their first dressing so conveniently. With moderate care he will accomplish this safely, and certainly better and more correctly.

Summer Management.—This consists in regularly stopping the laterals and keeping them tied in neatly to the wires. Speaking of wires reminds me that I have not yet described them. There should be three—one in the centre to tie the main stem to, and one on each side of it to tie the laterals to. Each wire should be about 9 inches from the glass, and 6 inches from wire to wire. To keep them in position, there should be strong iron pins, sharp at one end, or made with a screw, and an eye at the other end, the wires run through those eyes, and they keep the wires in their proper place. If the wire is pretty strong, the pins will do if placed 6 feet apart. Thus trained, when the Vines are in full bearing all their length, the bunches hang in two straight rows, and are very ornamental. The laterals should not be trained at right angles, but rather slanting upwards. If the Vines are very fruitful I would never allow more than one bunch to a shoot. The spurs should be as nearly as possible a foot apart, and at equal distances. When the Vines are in bloom, the air of the house should be moderately dry. In general, the air should be more moist during the night than during the day. Alternate moisture and dryness will cause the anther coverings to contract and expand, and eventually to crack and open when the pollen is ripe and ready to be shed upon the stigma. If all this has gone on properly, the berries will set freely and will soon begin to swell. Then is the time to commence thinning them—an operation that must not be neglected. Thin freely, and you will have larger berries, but handle the berries that are left as little as possible. Most of the kinds proper for a greenhouse have bunches with large shoulders. The bunch will be more symmetrical, and each berry will ripen more equally if those shoulders are tied up and spread out equally on each side. Some use pronged sticks for this purpose, but I judge that soft matting is the better article, and, besides that, the branches of the bunch can be spread out more equally. While the thinning is going on examine the laterals and ties, and top the one and adjust the other.

Syringing.—During summer, before the Grapes begin to colour, give them a good syringing once or twice a-week, especially after a hot, sunny day.

Air, of course, will be given very freely in the early stages of growth, because of the plants; but as soon as the greenhouse plants are removed out of doors towards the end of May or beginning of June, less air will do for the Vines. The stage of the greenhouse will then be filled with plants, such as Balsams, Cockscombs, &c., that will bear a higher temperature. In general, the rule should be to give air as soon as the thermometer indicates 65°, the maximum heat at noon should never exceed 70°. In cold, damp weather, a little artificial heat from the flues or hot-water pipes will be of great service.

When the Grapes are fully ripe, they will be attacked by wasps and other fruit-eating insects. The best remedy is to cover the air-giving openings with fine netting or canvass. Even a door of canvass will be of service to keep out those intruders. As the Grapes in a greenhouse will hang a long time (I have had them good till Christmas) the air in the

house should be kept as dry as is consistent with the health of the plants. No dead matters should be allowed in the house at all, such as yellow decaying leaves, or moss, or anything that will keep damp. The floors should be kept dry and clean, and abundance of air given during every dry day. Fortunately, all these precautions are equally as necessary for the health of the plants, as for keeping the Grapes from moulding and rotting on the Vines.

I have not mentioned *the border for Vines in a greenhouse*. The reader will remember what I said on Vine-borders, how they should be drained and made, but he might inquire, Will the border require covering to protect the roots? If it is properly drained, the only covering it will need is one that will keep off the heavy rains during autumn and winter. As the Vines in a greenhouse are not forced, but break naturally with the heat of the spring sun, which heat is applied also to the roots simultaneously, there is no necessity to heat the soil artificially. It is early-forced Vines that require this, in order that root action may be going on at the same time that the top action is set in motion by internal heat. On that point, however, I shall have much to say when I come to the stove and vinery culture of the Grape. T. APPLEBY.

(To be continued.)

OUR CULTIVATED SOILS.

(Continued from page 140.)

RED LOAMY SOIL.—The colour of a soil has really less to do with its fertility than is generally supposed, for it often happens that the colouring matter exercises little or no influence over it: consequently we may conclude that a good soil, like a good horse, cannot have a wrong colour. Certainly a dark-coloured soil absorbs more of the sun's rays, and becomes sooner heated than a light one, and in some districts a reddish-coloured soil is regarded the best; but this must not be confounded with the red clays found in some districts, which are amongst the most obstinate and least productive soils we have to deal with; neither ought we to include the red sandy soils in this class, which are more or less common in the north-western counties. One of the most agreeable working soils I ever had to deal with was of this description; but they are proverbially "hungry soils"—i.e., requiring manure very often, the porous character of the subsoil allowing everything to percolate through. A red loam is stiffer than this, and is said to produce excellent Wheat and other grain; but as I am not much acquainted with it, I cannot say much of its suitability for garden purposes.

BLACK SANDY SOIL.—There are some very rich soils of this description in various places; but most commonly in those level tracts of land bordering rivers, or some extensive plain, are of this character. The northern part of Cheshire and adjoining part of Lancashire is all of this deep, rich, black, open soil, producing the best of turf, and Potatoes. Carrots, Mangold Wurtzel, and other roots are grown in it to great perfection, and, in fact, such a soil seems available for almost everything. In the garden way Celery of the best description is grown; and the Peach, Grape, and Pine thrive to a degree not known in any other soil. A similar soil to this borders the Thames for a considerable way upwards; but it is not to be confounded with the black peaty soils of the few districts which contain scarcely a stone, and which are of so dead a level as hardly to allow of any drainage. Neither is this soil like the marsh soils of some of our coasts, which contain within themselves abundance of saline matters. The dark sandy soil alluded to partakes more of the character of a friable loam, easily breaking in pieces, yet containing sufficient unctuous matter within itself to retain moisture. The subsoil is often, but not always, sand, or a sort of sandy clay. Fruit trees—as Pears, Plums, Gooseberries, and Currants thrive remarkably well on it, and most of the gross-feeding vegetables are also at home here. As a soil to work it is pleasant and agreeable, and the teeth of the rake pass so smoothly through it, that the workman often sighs after it again when he removes to a soil of an opposite description.

DRY GRAVELLY OR STONY SOIL.—There are a great variety of these—some tolerably fertile, others hungry and ungrateful. So much depends on the subsoil and situation that no general rule can be laid down bearing on this; but in general a shallow gravelly soil with a similar bottom is unproductive, the substratum being often composed of materials of a pernicious character, while some of the stony soils are as much the other

way, trees and shrubs and many cultivated crops thriving remarkably well on them; so much depends on the character of the substratum. When this contains nothing hurtful to vegetation, hedges grow luxuriantly, and Cherry trees, Filberts, and sweet Chestnuts thrive, and many shrubs stand the winter well on such soils. But in hot, dry summers vegetation suffers much, excepting deeply-rooted trees, and even they are stunted when the subsoil is of a pernicious or impenetrable kind. Yew trees, with now and then Junipers, and perhaps Heath, abound, and Beech trees, Scotch Fir and Birch indicate a soil far from being a friendly one to the husbandman. Much, however, depends on the district; if in the west of England where they have much rain, vegetation will prosper better on such soils than in a drier locality; but at the best it is only a sorry soil.

LIGHT-COLOURED SANDY SOIL.—The valleys bordering many rivers and streams consist of this kind of soil, which is, doubtless, the accumulation of sandy matter washed down from the hills on each side, or deposited there by floods. This forms an excellent garden soil, produces most things in perfection, and corn and other products ripen tolerably early, and in good condition on it; and as it is generally porous enough to permit the water to drain off, so also it is deep enough to allow of a deep tillage to enable the roots of all descriptions of plants to penetrate below the reach of hot, dry summers, such soils are always favourites, and productive. On the other hand, low situations between hills suffer most from spring and autumn frosts; but even with that drawback they are early, compared with the rising grounds on both sides. Of course, care must be taken that they are not unrelieved with water. A marsh by the side of a river is a widely different thing from the soil just described.—J. ROBSON.

DIAL OF FLOWERS.

I SHALL feel very much obliged if you can give me any information concerning the flowers that open at every succeeding hour of the day, thereby forming a complete "Dial of Flowers." For instance: The Hibiscus opens at twelve at noon, and the Marvel of Peru at four A.M.—A SUBSCRIBER AND AMATEUR OF FLOWERS.

[We shall be obliged by any one who has made observations upon the diurnal opening of flowers communicating to us the results of those observations. The following is extracted from the "Lexicon" of the Rev. P. Keith:—

"Of many plants it is not enough merely to say that they open their flowers in the morning, and shut them again in the evening. They have fixed and appointed periods of opening and of shutting; some earlier in the day, and some later, but always at the same hour for the same species; and this succession of periods Linnaeus, in his love of metaphor, denominated the *Horologium Floræ*. Flowers requiring but a slight application of stimulus open early in the morning; while others requiring more open somewhat later. Some do not open till noon, or till an hour later still; and some, whose extreme delicacy cannot bear the action of light at all, open only at night.

"According to Linnaeus, the following plants open and shut their flowers as follows (*Phil. Bot.* 273):—

Tragopogon luteum	opens at 3 A.M. and shuts at 9 A.M.	
Crepis tectorum	4	10
Sonchus oleraceus	5	11
Sonchus repens	6	12
Lactuca sativa	7	10
Hieracium pilosella	8	2 P.M.
Calendula arvensis	9	3
Mesembryanthemum neapolitanum	10	3
Ornithogalum umbellatum (Dec.)	11	3
Most Mesembryanthemums	12	"
Scilla pomeridiana	3 P.M.	
Silene noctiflora	6	
Cereus grandiflorus	7 or 8	
Convolvulus purpureus	9 or 10	

"The above flowers are said to be equinoctial, because they open at a certain fixed hour of the day, and shut at another, and so on, for many days in succession, with a few exceptions; though we do not after all see the propriety of the term. But some flowers open only to expand and to fall in the course of one day, or at least to open no more, such as those of Cistus and Linum, and such are said to be ephemeral.

"Is light the sole cause of the above phenomena, or is it attributable partly to heat? De Candolle regards it as being attributable to the action of light solely. He observed that flowers opened at the same hour, whether in the open air or in a

hothouse. He placed certain flowers under water, and they opened at the same hours as when in the open air.—(*Phys. Veg.* ii. 486.) Yet it has been ascertained that the flowers of plants which are removed from a warmer to a colder climate, expand at a later hour in the latter than in the former. Thus a flower that opens at six o'clock in the morning at Senegal will not open in France or in England till eight or nine, nor in Sweden till ten. A flower that opens at ten o'clock at Senegal will not open in France or in England till noon, or later, and in Sweden not at all; and a flower that does not open at Senegal till noon or later, will not open at all in France or in England. This seems as if heat, or the want of it, were also instrumental in the opening or shutting of flowers; though the opening of such as blow only in the night cannot be attributed either to light or to heat.—(*Famill. des Plant.* i. 104. 1773.)

"But the opening and shutting of some flowers depends not so much on the action of the stimulus of light as on the existing state of the atmosphere, and hence their opening and shutting betokens change. If the Siberian Sowthistle shuts at night the ensuing day will be fine; if it opens it will be cloudy and rainy. If the African Marigold continues shut after seven o'clock in the morning, rain is near at hand; and if *Convolvulus arvensis*, or *Anagallis arvensis*, is even already open, it will shut upon the approach of rain—the last of which, from its peculiar unscopability, has obtained the name of the Poor Man's Weather-glass."

REPORT ON THE GARDEN PEAS,

GROWN AT CHISWICK DURING 1860.

By ROBERT HOGG, LL.D., F.R.H.S., Secretary to the Fruit Committee.

(Continued from page 139.)

47. Lynn's Wrinkled MarrowNUTTING & SONS.

The plant is a robust grower; 3 feet high, and with dark green and much blotched foliage. The stem is simple, producing from twelve to fourteen pods, which are in pairs, and contain from six to eight Peas in each. The ripe seed is white, wrinkled, and with a black hilum, like the Egg Pea.

Sown February 19th; bloomed June 28th; slatted July 6th; and ready for use July 22nd.

This is a very hardy variety, and as such is grown rather extensively in the neighbourhood of some of the manufacturing towns in the north; but it is not a desirable sort.

48. Knight's Dwarf White...NOBLE, COOPER, & BOLTON.

The plant is a strong grower, 2½ feet to 3 feet high. The stem is much branched, and the foliage deep green and much blotched. The pods are produced in pairs, and are from twelve to sixteen on a plant, containing six to seven large Peas in each. The ripe seed is white and wrinkled.

Sown February 19th; bloomed July 1st; slatted July 9th; and fit to gather July 24th.

49. Knight's Tall White...NOBLE, COOPER, & BOLTON.

This is a strong and robust grower, 6 feet to 7 feet high. The stem is much branched, and keeps on growing and producing pods till late in the season. The foliage is dark green and much blotched. The pods are produced in pairs to the number of twelve to eighteen on a plant, and they contain from seven to eight Peas in each, which are very closely compressed. The ripe seed is white and wrinkled.

Sown February 19th; bloomed July 1st; slatted July 9th; and fit for gathering July 24th.

VII. GREEN MARROW KNIGHT'S PEAS.

Ripe seed mixed white and olive. Foliage dark green and blotched. Pods dark dull green, very glaucous.

50. Ne Plus Ultra.....NOBLE, COOPER, & BOLTON.

SYN: *Jeyes' Conqueror*.....NUTTING & SONS.

Payne's Conqueror ...HURST & M'MULLEN.

This is of a strong and robust habit of growth, 6 feet to 7 feet high, and with a branching stem and dark green blotched foliage. The pods are from twelve to eighteen on each plant, mostly in pairs, and contain seven very large Peas, which are of a dark, dull green colour, like those of the Green Marrows. The ripe seed is mixed white and olive.

Sown February 19th; bloomed June 16th; slatted June 26th; and fit for gathering July 10th.

This is one of the best Peas in cultivation, being an abundant bearer, as early as the Early Green Marrow, and having dark-coloured pods and Peas similar to those of that variety.

51. General WyndhamNOBLE, COOPER, & BOLTON.

SYN: *Buckley's Gen. Wyndham* HURST & M'MULLEN.

The plant is of a robust habit, 6 feet to 7 feet high, and frequently branched. The foliage is dark green and blotched. The pods are either single or in pairs, and number from ten to fourteen on each plant. They contain eight very large Peas, which are of the deep dull green colour of the Early Green Marrow. The ripe seed is white and olive mixed.

Sown February 19th; bloomed June 23rd; slatted July 2nd; and fit for use July 20th.

This is a valuable acquisition, and has evidently been raised from *Ne Plus Ultra*; but it is a much more robust grower and produces much larger pods. The plant continues growing, blooming, and podding till very late in the season, and when this is in the full vigour of growth, *Ne Plus Ultra* is ripening off. The Peas when cooked are of a fine, bright, green colour, and unlike those of any other variety.

THERMOMETRICAL OBSERVATIONS.

THE fatal consequences arising from last winter to plants previously considered hardy, and the discrepancy of those consequences, have aroused the gardener's attention to the importance of thermometrical observations. Seeking for an explanation of but one fact among those consequences justifies that aroused attention, and that fact is this: *Cupressus macrocarpa* was killed by last winter's frosts in the neighbourhood of Worcester, whilst it is quite uninjured on the brow of a chalk hill near Winchester. Why was this? What were the relative atmospheric and underground temperatures of the two places? What and when were the most violent transitions of temperature?

To these queries we can obtain no reply. No reliable thermometrical observations were made; yet it is obvious that truthful replies to those queries would afford information most important for the gardener to possess.

If such replies could have been obtained, we incline to believe it would have been found that, although the atmospheric temperatures on the Winchester hill were lower than those at Worcester, yet that the soil temperature never descended so low at Winchester as at Worcester. Such variations have many controlling causes, for, as observed by Dr. Thomson, the temperature is altered by an almost infinite number of circumstances; thus, altitude, latitude, longitude, horary and seasonal periods, the presence of aqueous meteors, winds, and the physical relations of the locality; even the aspect of the horizon, whether it is rugged or unbroken by lofty eminences, the chemical nature and colour of the soil, influence the result. Subject, however, to numerous fluctuations, we nevertheless observe that there are two stated periods of the day when the temperature reaches a maximum and minimum. The warmest period is generally from two to three hours after the sun has passed the meridian, the difference depending upon season; the coldest is nearly an hour before sunrise. A mean may be conveniently obtained by recording the oscillations of the thermometer at suitable intervals, and thus the toils of hourly observation dispensed with. Thus the sum of the indications at 6 A.M., 2 and 10 P.M., or, as suggested by Schouw, at 7 A.M., noon, and 10 P.M., divided by 3, will give a near approximation to the diurnal temperature. From observations made by Professor Dewey in North America, it would appear that the result obtained at the homonymous hours of 10 A.M. and 10 P.M. afforded an approximation of 5-100ths of a degree to the true mean diurnal temperature. Though the maximum temperature occurs some time after the sun has culminated, we find that proximity to coasts accelerates the epoch; and in tropical regions the sea-breeze still farther modifies the result. The same has been found on mountain tops; nor is it at all remarkable: for, let it be observed, that in the plain, not only is the atmosphere warmed by direct solar rays, but by those radiated from the ground; upon the mountain top there will be a greater absorption of caloric and less radiation, more heat being abstracted by conduction there than below, where the temperature of the earth is higher and more equally diffused. The temperature, then, upon those lofty spots will depend chiefly upon the sun's direct caloric action; and as those rays are most powerful which pierce the thinnest atmosphere—i.e., when the sun is on the meridian, the hottest period of the day will be at, or very soon after, culmination.—(*Elements of Meteorology*).

To obtain accurate comparative observations and records of

the maxima and minima temperatures daily, requires not only that the thermometers should be accurately and similarly graduated, but that they should be similarly exposed and similarly protected in every respect.

Mr. E. J. Lowe published some years since, in the "Gardener's Magazine of Botany," the following judicious directions upon this subject:—

"Thermometers for comparison should all be placed at a certain height from the ground: they should all face the north (except those which are required to register the maximum temperature in the sunshine, which should face the south); they should not be influenced by radiated heat, by currents, by reflected heat, such as is communicated from an opposite wall, by absorption of heat from the wall or woodwork to which the thermometer is attached; and, in short, they should be situated where there is a free passage of air.

"With regard to the height that a thermometer is placed above the ground, it is ascertained that an inch occasionally makes a difference of a few degrees. Thermometers placed at various heights do not vary much from each other in cloudy weather; but, with a cloudless sky the difference is very great: as an illustration we shall quote an example—viz., March 13th, 1845, 9h. 10m. p.m., a thermometer on the grass had fallen to 4.5°, 2 feet above the grass it stood 15°, and 7 feet above the grass at 18.5°. Here is a difference of 10½°, or three times as much between the temperature of the grass and 2 feet above it; and between the grass and 7 feet, of 14°, or four times as much.

"With respect to the aspect of thermometers, we shall give an instance which occurred at the same time as the last observation. A thermometer placed 14 feet above the ground, with a south-east aspect was 15°, with a north aspect 17°, with a north-east aspect 18°, and with a south-west aspect 19°.

"It cannot be expected that thermometers, placed as they

we shall describe is so arranged that it may be placed in any eligible situation; it commands a true north and south aspect; the instruments can be read off with the greatest facility, and they will be at a known distance from the ground; the instruments on the south face will have the meridian sun, and those on the north face will be always in the shade. The instrument is not costly, and were this stand universally

adopted, observations, whether recorded here or at the antipodes, could be compared with each other with far less chance of error than has hitherto been the case.

"Fig. 1 is a view of the stand. It is composed of white deal boards, and can be constructed by any carpenter. It consists of an oblong trunk *T*, 12 inches by 8 inches outside measure, to the opposite sides of which trunk are nailed boards, *b b*, at the distance of three quarters of an inch, and projecting about 6 inches from the trunk towards the north. Outside of these are nailed other thin boards, *c c*, full half an inch distant, and projecting about 4 inches beyond the last-mentioned boards, also towards the north. These sides being thus multiple, prevent the sun from heating the interior of the stand, where the thermometers are placed. The top, or pent-board, *P*, is made double, and the boards are placed fully three quarters of an inch distant from each other, and come so forward as to overhang by a full inch. The legs, *L L*, of the stand are merely the continuation of the sides of the trunk. The board, or feet, *F F*, are loaded or fixed to the ground to sustain the force of the wind. The interior, *T*, is blackened to prevent strong reflections of light.

"Fig. 4 is a ground plan, or bird's-eye view of the machine. The sides and woodwork generally are of three-quarter-inch white deal. The distance or space between the sides of the trunk, *T* (fig. 1), and the board, or inner side (fig. 4), is three quarters of an inch; and, the distance from that board to the outer side (fig. 4), is full half an inch. The

generally are, may be depended upon, some facing the north, others the south; some the north-east, others the north-west; some 3 feet to 5 feet above the ground, others 10 feet to 20 feet; some sheltered by a high wall, others by low palings; some touching a wall, others distant from it; and some in the angle of a high building (cool as a cellar), and others exposed to the rays of the sun at one or other hour during the day.

"The Lawson Meteorological Thermometer Stand,' which

narrow boards (fig. 4), are to be nailed, with studs intervening, to the middle board or side, and are for the purpose of preventing the sun from shining between the trunk and the sides of the stand, when near the meridian. The sides are fixed one upon another at the required distances (viz., three quarters of an inch and half an inch), by numerous wooden studs, partially shown at figs. 1 and 2, about three quarters of an inch diameter, and the screws passed through the sides and studs, fixing the whole

firmly together. The whole is to be painted white, except the trunk *r*, which should be black.

"Fig. 2 is the view of the north side of the stand. No. 1 is an index thermometer to give the greatest cold of the night. The thermometer inclines, the ball end being the lowest, in order that the index, by being assisted by gravity, will move more easily. No. 2 is an index thermometer to show the greatest heat of the day; for the same reason it is also placed on an

incline, the ball end being the highest. No. 4 are a pair of thermometers called the wet and dry ball thermometers, to show the power of the air to evaporate water. *v* is a vase or cistern of water for the wet ball thermometer; it is placed on the outside of the thermometer, to which a cotton wick is to be attached to connect it with the water, and at about the same elevation as the ball of the thermometer, in order that the evaporation from the vessel of water may not influence the thermometer on the other side, which is to be the dry ball thermometer; for, in some careful experiments which I made with a vessel placed beneath the balls, it was found that the dry ball was lowered from 0.2° to 0.3°, which, though apparently a small error, is a serious amount in the main difference between the readings of the dry and wet ball thermometers.

"Fig. 3 is the view of the south side of the stand. No. 3 is an index mercurial thermometer, with a black ball to give the greatest solar heat. *B* is a rain gauge on Glaisher's construction; and *R* is a measure into which rain is to be poured for measurement."

For ascertaining the temperature of the soil at various depths we recommend three tin tubes to be sunk in it in a place fully exposed to the sun, but far from a wall or other shelter; each tube to be about 2 inches in diameter, and of the respective depths of

2½ feet, 1½ foot, and 9 inches. These tubes should have in each a thermometer such as is represented at page 118 of our present volume, but with the shank lengthened so as to correspond with the depth of the tube in which it is placed. These tubes should be covered over by a hand-light glazed only on the top to exclude rain from entering the tubes, but entirely open at the sides to admit freely the admission of the air. The thermometers should be well packed into the tubes with cotton to exclude the atmospheric temperature.

The importance of ascertaining for a certainty that the soil is of a temperature correctly relative to that of the air above it is demonstrated by the fact, that naturally its average temperature is always higher than that of the air. In other words, the roots on the average are kept warmer than the branches.

From observations made at Chiswick during six years (1838—1847) Mr. Robert

Thompson gives the following epitome of results:—

"The hottest year as regards the temperature of the earth, 1846, afforded a mean temperature of 52° 32' at 1 foot deep; and 52° 55' at 2 feet deep. In the coldest year, 1845, the mean temperature at 1 foot deep was 48° 95'; and at 2 feet deep 49° 44'. The respective differences of the two thermometers in these hottest and coldest years were 3° 37' at 1 foot deep, and 3° 41' at 2 feet. The mean temperature of the air was 51° 45' in 1846, and 47° 92' in 1845; the difference being 3° 53'.

"On the average of the six years the earth is coldest in February, and warmest in July. The mean temperature of the air is also highest in July, but it is lowest in January. Throughout the months the gradations of temperature are not uniform. The monthly progression is as follows:—

"Temperature increases.

	Feb. Mar.	April.	May.	June.	July.
1 foot deep (Lowest)	5:10	5:01	7:32	7:65	5:35
2 feet deep (Lowest)	2:25	4:47	6:39	6:77	3:00

POMOLOGICAL CLEANINGS.

EARLY STRAWBERRIES IN THE NORTH.—In your JOURNAL OF HORTICULTURE, of June 4th, I observe with great interest an article on early Strawberries, from Ferdinand Gloede, Esq., of Sablons, France, "the king of Strawberry growers," stating that he had the May Queen ripe on the 18th of April; and I, living in the north of England, in the county of Durham, close to Yarm, Yorkshire, may be permitted to say that I had the May Queen ripe on the 4th of June. Had it not been for the terrible frosts of the 10th and 11th of May which killed the first blooms, I should have had it ripe about the middle or latter end

of May. The line is five years old and is covered with fruit. It is growing near a Privet hedge, and is sheltered a little from the north. Out of a stock of more than two hundred varieties I cannot find one that will be ripe for at least a week to come. The weather has been very bleak for the last week with cold east winds and rain.—WILLIAM JAS. NICHOLSON, *Egglescliffe, near Yarm, Yorkshire.*

CRYSTAL PALACE ROSE SHOW.—The schedule of prizes and the rules are now issued, and are very liberal. The classes embrace amateurs and growers for sale; Roses in pots, new

Roses, and cut flowers. Altogether £150 are given in prizes, being a larger amount than has ever before been offered for Roses only; and this year a greater facility is offered to exhibitors in the first four classes. One good truss of all good Roses is now substituted for the three trusses of former shows. Intending exhibitors must give notice to Mr. W. Houghton, Secretary to the Rose Show, on or before Saturday, the 29th of June, and receive from him the printed form in which the entries are made, so as to leave no room for mistakes or confusion on the morning of the Show; and to prevent a serious mistake which we noticed last year on the part of several exhibitors, all trusses must show their natural leaves growing on the stalk. Other Rose leaves, if they are stuck in under the flowers, will disqualify the exhibitor from taking a prize; and no exhibitor can take more than one prize in each class. The rules and the whole arrangements for the Great Rose Show appear to us sound, and in principle judicious in their application.

VEGETABLE PRODUCTS OF THE HIMALAYAS.

(Continued from page 142.)

THE Morenda Pine is, I believe, peculiar to the Himalayas, and grows in the middle and higher regions, from an elevation of 6000 feet to near the limits of forest. In the great Oak forests of the middle ranges it occurs at intervals, sometimes singly, sometimes in clusters, and its very dark foliage, and spire-like top towering above the other forest trees, render it a conspicuous object. On some of the hills nearer the snow, where Pine is the prevailing wood, it almost monopolises the forest. The Morenda is a large and very handsome tree, the trunk perfectly straight, often upwards of 20 feet in circumference at the base, and sometimes reaching a height of between 150 feet to 200 feet. The branches, which in a large tree commence about 20 feet from the ground, are very short, in some cases not extending more than a few feet from the trunk, and very regular all the way up, which adds to the apparent height of the tree. The wood is of little use except for in-door work, as, when exposed to the atmosphere, it soon decays.

The Rye is generally found growing with the Morenda; but is not nearly so plentiful, and never forms a forest of itself. Seldom, indeed, are a dozen trees seen together without some of the latter or the Cheel amongst them. It is in all respects a more tender tree, and entirely ceases upwards of 1000 feet lower down. In size it is nearly equal, and is, perhaps, still more ornamental. The branches are slender and drooping, and the foliage partakes of the same character. The wood is of much the same quality as that of the Morenda.

The Kolm, or common Pine, grows only on the lower hills, ceasing altogether at a little above 6000 feet. Forests of it extend over a great portion of the lower ranges, where it and common Oak are the principal trees. The Kolm forests are always very open, the trees some distance apart, and it is rarely or never any underwood grows beneath them. In many places Spear-grass alone covers the ground for miles where these trees form the forest. The Kolm has little ornamental about it. It is often a large irregular tree for a Pine, with wide-spreading and crooked branches growing far apart. The wood is a common coarse deal, only fit for in-door purposes, and, probably, would not repay the cost of cutting and transporting to the plains, even where the rivers are available; but as it yields excellent tar these forests may yet be turned to some advantage in a commercial point of view.

These are all the cone-bearing Pines in this part of the Himalayas. The Leuro is a kind of Cypress, the berries and leaves of which are similar to the long slender species in our English gardens and pleasure grounds, but here it grows into a tree nearly as large as the Morenda or Rye. It is very rare, and found only in a few places in the middle regions. The wood is hard and extremely heavy, but does not appear to be very durable. A peculiar quality, the very reverse of all Pine is, that it is very difficult to burn; so much so that it is impossible to make a good fire of it alone. Another Cypress, a much smaller tree, is found when we approach the dry atmosphere of Thibet, the wood of which has a fragrant smell and is often used to burn as incense. The Yew is scattered through all the forests between 7000 feet and 9000 feet; though itself often a tolerable sized tree, it is so overtopped by the gigantic Oaks and Pines as to have almost the character of underwood. Its wood is valued as much as Cedar, and supposed to be still more durable.

The first Oak met with is the Banj, which I have named

common, to distinguish it from the two others. It begins at about 3500 feet, and almost ceases at 8000. The Oak forests of the lower ranges are composed almost exclusively of this species, as well as the lower part of those further in the interior. There is nothing remarkable about the tree; it is in appearance some thing like the English Oak, but seldom attains to any extraordinary size. The wood is coarse and rarely used except for firewood. Burning well while green, it is the principal wood consumed in the houses at the different sanatariums. The three Himalayan Oaks are all evergreens.

The next in order is the Moura, a large and handsome tree. The branches are rather slender and very numerous, and the leaves small and of a particularly bright hue. It grows sparingly near the summits of the lower ranges amongst the common Oaks, becoming more common in the great forests of the interior, but is nowhere so numerous as to give a decided character to any part. It seems to prefer sheltered nooks and hollows, and a rich damp soil. Its range is from 5000 feet to nearly 9000 feet. It attains to a great size, the trunks of some being 20 feet in circumference. The wood is excellent, uniting in itself the best qualities of English Oak and Ash, the hardness and durability of the former with the toughness and flexibility of the latter. The leaves of both this and the common Oak are eaten with avidity by sheep and goats. In winter, when the grass is so dried up as to afford little nourishment, the shepherds ascend the trees, lopping off all the small branches, which as they fall are soon stripped of their leaves by the hungry flock underneath. Large bundles are also taken home regularly every evening for them to eat during the night. Of the two trees the Moura is considered the most nourishing, and in some districts each family has one or more trees planted near the village, which furnish a ready supply for a few days after severe snow, when it could not be otherwise obtained without a great deal more exposure to the inclement weather. These, being stripped of their small branches almost every year, grow so compact as a clipped Box tree, and, being, often of enormous size, are the most magnificent trees of the kind one can conceive.

The Khurso is an Oak confined to the higher hills. It is first met with at an elevation of about 7000 feet, and extends to nearly 11,000 feet. In the great Oak forests of the interior the lower portions consist of the two former, which gradually get mixed with Khurso, till this becomes the sole occupant of the higher. In appearance it somewhat resembles the common Oak, but has some peculiar characteristics. The leaves, particularly in young trees, are very prickly, as much so as Holly, and the acorns are about three times the size of those of the other Oaks. The trunk is generally very straight, and for 40 feet or 50 feet scarcely decreases at all in thickness. The branches are short, so that the trees grow very close together. An acre of ground in any Khurso forest would yield more than treble the quantity of timber the same area in any other Oak one would. The wood, though inferior to the Moura, is of a very fair quality. Though found on all faces, the Khurso prefers the southern and eastern slopes, as the Morenda and Rye Pines do the northern and western. It is not unusual to find the forest on one side of a ridge all Khurso, while on the other it is composed chiefly of the two Pines.

The Horse Chestnut grows to an immense size. It is generally found in groves of from fifty to a hundred trees, in the Oak and Morenda Pine forests of the interior, where the ground is rather damp and not very steep. These Chestnut groves, surrounded closely by the other forest trees, have rarely any growing amongst them, appropriating the entire space to their own species; and it is but seldom a Chestnut tree is found growing alone amongst other kinds. The Sycamore and Filbert grow scattered at random in similar localities in the higher forests. The former attains to a great size, and several majestic individuals are sometimes found growing by themselves in an open glade, or some grassy flat bordering a large stream, and giving quite a park-like appearance to the spot. The round knobby excrescences on the trunk of the Sycamore are cut out, and form a considerable article of export with Thibet, where they are made into drinking-cups something the shape of a teacup with a turned rim. They take a beautiful polish, and the wood is very pretty, being mottled something like Bird's-eye Maple. Roughly turned into something of the required shape, they sell in Thibet at from four to eight for a rupee; but one is occasionally found which itself fetches from ten to twenty rupees. These are called *jat ones*, but to a stranger they do not appear to differ in the slightest degree from the others. Even the men who collect them in the

forest can see no difference; and when they are so fortunate as to find one, which they know by the bark all falling off on giving it a slight tap, they keep it apart from the rest, or mark it in some particular manner, as the only means of knowing it again. The Tartars, they say, can distinguish them at once. The alleged reason of their great value is, on this side the hills, that any poisonous liquid poured into the cup is at once detected; what the real one may be it is impossible even to conjecture, and, their ideas being so much at variance with our own, perhaps no one but an inhabitant of the celestial empire could appreciate it. These jat cups are but rarely met with. A man may cut a thousand from the trees and not find one; but he always gives every knob the gentle tap by which they are discovered before commencing to cut it out. In Huc's "Travels through Tartary," he mentions going into a cup shop at Lhassa, and, on asking for a cup, being shown one of these jat ones, which was carefully taken out of several wrappers of silk paper, and being astounded at the price asked for it. I cannot remember whether he was told what there was peculiar in it or not, but it seems to show that the Tartars, at least, do see something.

Apricots grow only in the orchards, and most abundantly in the higher regions. The fruit is small and often very sour, the effect, probably, of the trees never being pruned; but some are of really tolerable flavour. Being cultivated merely for the oil, quantity, not quality, is what the Puharie looks for. When ripe the fruit is collected in large heaps, and covered with green grass and bushes till completely rotten, when the mass is taken in baskets to a spout or fall of water, which soon carries away the pulpy portion and leaves only the stones. These are put by to have the kernels extracted at convenience. So fond of spirituous liquor as they are in the higher hills, and regularly distilling it from grain, it is wonderful the Puharies have not discovered that a spirit might be obtained from the fruit, and thus the pulpy portion, now entirely wasted, made of use as well as the stones. When they take it to wash, it appears to be in a state of fermentation just ready for the still. The pounded cake, after the oil has been extracted, is kept for various purposes. It is considered a good thing to eat when crossing high passes where the air is very rarefied, and, when old, is an excellent remedy for certain urinary diseases. Though perfectly innoxious to the human system, it is a deadly poison to the canine race. A small quantity of the best and ripest fruit is dried in the sun, and some when partially dry is pounded and made into small cakes seasoned with salt and pepper. These cakes are also considered a good remedy or preventive for the sickness and headache invariably expected when crossing very high passes. The other fruit trees of these hills are Mangoes, Peaches, Nectarines, Pomegranates, Limes, Wild Cherries, Figs, Mulberries, Medlars, and a few others peculiar to the Himalayas. These and many other forest trees not described, being in no way remarkable, it would be uninteresting to notice them in detail.

Of the underwood, the only thing worthy of particular notice is the Ringall, a kind of hollow Bamboo cane, which grows throughout the middle regions. There are several varieties, differing but slightly in appearance, each having particular localities determined by elevation. All are used for basket-making, and the best, which grows in the great Oak and Morenda Pine forests of the interior, forms an article of export to the plains, where it is used to make hookah pipes. The cane is cut into pieces about 4 feet long, and carried in bundles to the marts at the foot of the hills. A man will carry 500 pieces, for which he gets from 2s. to 3s.—no very handsome remuneration for the trouble of cutting, drying, and carrying them five or six long days' march on his back. The Ringall, when most luxuriant, grows in clusters, the largest canes being from 3 inches to 6 inches in circumference, and from 20 feet to 30 feet long. When dead and perfectly dry they burn well, and are used for torchees where Pine wood is not procurable. The Ringall is well worth introducing into our English woods, where, the climate being very similar to that of its native region, it would doubtless be easily naturalised. It would not interfere with the forest trees, and would be of great value. Nothing can be better adapted to basket-making in all its branches; it makes handsome walking-canes, and can be used in the same manner as molacca-cane, for making mats, &c.

Above the forest, where the hills are high enough, comes a region of herbaceous vegetation, extending from about 12,000 feet to 14,000 feet, from whence the hills on the Indian side are clothed with perpetual snow. This region, from the first general fall of snow, which sometimes occurs as early as October, is

covered with it till May, and is not entirely free till near the end of June. In its short summer it is clothed with rich and luxuriant herbage, which springs up as soon as the snow disappears. The grass in a few weeks is in many places 2 feet or 3 feet high, and a great variety of flowering plants deck every slope with a thousand colours. The Cowslips particularly are very rich, of all colours, from the brightest yellow to a dark purple, and are much larger and finer flowers than any of the kind in an English garden. This region forms the summer pasture ground of the flocks possessed by the mountaineers; the shepherds being careful to avoid those places where the poisonous Aconite grows in profusion. On the Indian side of the great Himalayan chain there is little or no space between the limit of vegetation and that of perpetual snow; they join together without any appearance of that entirely barren strip of bare ground which on the Thibetian side divides the two. A great deal of controversy has arisen in trying to decide at what elevation to fix the limit of perpetual snow; but in truth no limit can be fixed, as it varies and is entirely determined by the climate. Where the hills are fully exposed to the influence of the rainy season, as is the case in the greater portion of Gurwhal, it is lowest, and may be fixed generally at 14,500 feet. Where the hills are less exposed to the rains, the climate becomes drier and the limit of perpetual snow higher, till, as in Thibet, entirely beyond their influence, and with a cold but remarkably dry climate, it is not less than 20,000 feet; corn growing at 14,000 feet, and the pasture grounds for cattle being often between 16,000 feet and 17,000 feet. If we search for immediate causes, the principal one may be that on the Indian side, the sun throughout the summer is generally obscured by clouds and has little influence; while on the Thibetian, a sky rarely obscured by even a passing cloud leaves the hills exposed to its full power. When speaking of the limit of snow, it must be borne in mind that this is always calculated on exposed hill-sides, as in ravines and sheltered places it remains all the year round much lower. In such situations beds of snow are often seen at the close of summer at 12,000 feet, and many of the large glaciers are not more than 11,000 feet.—(*A Summer Ramble in the Himalayas.*)

CULTURE OF SORGHUM,

AND THE MANUFACTURE OF SYRUP AND SUGAR THEREFROM.

HAVING watched with growing interest the experiments instituted both by myself and others on the Chinese Sugar-Cane; believing that soon, the North-West at least, will supply its own demand for syrup and sugar; and, knowing that the current year will witness a vast increase in the amount of ground planted with Sorghum; I feel justified in adding my mite to the general fund of information. When first introduced to this country the most extravagant anticipations were indulged in by the growers thereof. To read some of the accounts in the various Patent-office reports, one would be led to suppose that all that was necessary to be done in order to make sugar was to boil to a certain thickness (after clarification) and then empty into tubs or rats and the work was finished. In a day or so the mass would be crystallised. Sad experience has taught us better. But while we must moderate our anticipations somewhat, at any rate for the present, let us by no means become discouraged. The sugar is there! We must learn, and we are learning, to get it out. It is present in quantities amply sufficient to render the cultivation and manufacture of Sorghum profitable. The advice given below is founded on experiments carried on by myself, and when failure has occurred I shall faithfully state it, that the observer may take warning therefrom. With this lengthy premise I will give what I believe to be the best method of cultivating the cane.

First Selection of Soil.—This important point has been almost wholly overlooked. It has generally been supposed that the larger the stalk the greater the yield of saccharine matter, and, of course, the richest, deepest mould has been selected for its growth. This is a great mistake. I will illustrate by a little experiment of my own. Part of my cane grew on a southern slope of very moderate richness, and part on a bottom the very reverse in fertility. The stalks in the latter position were of much larger growth than those in the former, yet the first produced more syrup per acre of a superior quality. Besides, I found no difficulty in procuring its granulation, while the latter would not crystallise. The soil of the slope was a reddish-brown, slightly intermixed with sand. The cane brought to my mill

from the borders of the prairie and from timber land invariably excelled in quality that grown in the deep, rich soil of the centre of the prairie. I will enter into no learned disquisition on the chemical properties of the said soils. I am writing for the intelligent farmer, not for chemists. Plain, simple facts, couched in plain, simple language, are what we need.

It is unnecessary, one would suppose, to remark that the ground should be put in perfect tilth to receive the seed, had not ocular demonstration afforded abundant proof to the contrary. The plant when young is quite feeble in growth, and amply repays any extra care exercised in preparation for planting. As regards manure, the present richness of the soil should be the guide taken in connection with the facts stated above concerning the overgrowth of stalk.

Time of Planting.—The experience of the past year has proved that the seed can safely be sown a week or ten days earlier than corn; and as the manufacturing season is so short, every day we can add to it is precious. Some planted by a neighbour on the 25th of March was the best cane in the prairie. A mild frost seems to inflict no injury. My own was planted on the 16th of April, and was ready to work up by the 21st of August. (I am writing from Montgomery county, near the centre of the State.) The seed, being slow to germinate, should be sprouted before sowing, in the same manner as corn. A week can be gained thus. As there is a period embracing from four to six days, in which the cane is in a greater degree of perfection for manufacturing, I would strongly urge sowing in such succession as will insure its being worked up during that period. The cultivator will, of course, take into consideration his facilities for working up, in regulating their succession. I regard this as one of the most important points in the whole business. The syrup made at such period, will, if properly managed, be of a beautiful transparent colour, entirely free from any foreign taste or smell; besides, this is the only time that crystals can be produced with any certainty. I have no doubt that the occasionally-successful attempts at granulation which have occurred from year to year have resulted from accidental manufacture within this period. I refer, of course, to experiments in the hands of farmers, not of chemists, who can make sugar from a worn-out hickory shirt. This period commences when the seed is fully in the "dough," and lasts until it is nearly, not quite, ripe. If this statement conflicts with the commonly received opinion, all I can say is, Try it! Such is my experience. When the first frost comes, all this cane which remains should be cut and carefully protected from the weather, by being placed under a shed, or covered over with straw, so that neither the sun nor wind can act upon it. By covering so as to prevent freezing, good second-rate syrup (but not sugar) can be made until the 1st of December, and thus lengthen the manufacturing season a whole month. It will not do to carelessly throw the stalks in a pile in the open air, as has been too commonly practised heretofore. When I first commenced the business I was told that I could cord it up around the yard, and it would keep good for a month or six weeks. It is a grave error; most have doubtless found it so by this time.

Manner of Planting.—The seed should be sown in drills 3 feet apart, and seed enough sown in the drills to insure one plant every 12 inches. Thinner than this I regard not only as a waste of land, but as rendering the stalks liable to too great a growth, which I have before stated to be an injury. Shallow sowing (from 1 inch to 1½ inch) insures speedy germination more certainly. Cultivate carefully with the hoe and cultivator. I saw an article which stated that breaking the roots with a deep ploughing just as the seed commenced to turn greatly increases the amount of saccharine matter. I have not tried it.

Stripping and Topping.—The cane should be stripped at least one week before using. This course certainly does enrich the cane, and also renders it easy to save the blades for fodder, which should be bound and shocked between the rows. The stripping can be performed either with the two hands encased in buckskin gloves or by means of a wooden knife about five feet long as recommended by Mr. Cook. Our experience led us to prefer the hands, as we could strip a stalk, and sometimes two or three, at a single stroke, and retain the leaves ready to bind, saving thereby considerable labour.

The cane should not be topped until ready for cutting. If this is performed sooner the formation of sugar is immediately checked, by the efforts of the cane to replace the lost heads or panicles. Some which I topped at the time of stripping (ten days before cutting) yielded juice which contained only 12 per

cent. syrup, while that from cane untopped until the day of using yielded 18 and 20 per cent. Neither would the latter granulate. It can best be topped by hauling to the mill, and, laying the heads evenly, cut them off with a hatchet.

Time of Cutting.—Do not cut until the very day of using, if it can possibly be avoided. From the day it is cut it commences to deteriorate. This is a fixed fact. A change in the chemical constituents immediately begins, which soon destroys the granulating power, and, if the weather happens to be warm, brings on acetous fermentation. This many have learned to their cost.

Most Favourable Period for Manufacture.—This commences, as I have before stated, when the seed is fully in the "dough," and continues until it is nearly ripe. The past season has afforded abundant proof that this is the fact. Cane having been planted quite early (compared with former years) most of it in this region was fully ripe a month before frost; and as the facilities for manufacturing were very few, a large quantity necessarily stood in the field uncut until wanted at the mill. An acid, seemingly identical with tartaric acid, commenced forming as soon as it became thoroughly ripe, which requires the use of neutralising agents, thereby injuring both colour and taste. That made in the above-mentioned period required nothing of the sort.

If, however, the manufacture is so delayed by breakage of machinery or any other cause, that the cane sours after being cut, the acidity can be thoroughly neutralised by using sufficient alkali. The sourer the juice the more alkali. The colour is injured thereby, but that is comparatively a matter of small moment. I found that in some very acid juice a tablespoonful of strong soda was required for a gallon of syrup. For a few days there was a decided smell of the alkali, but it presently passed away and the syrup proved to be quite a good article, and a portion of it has grained in the barrel.

(To be continued.)

DIBBLES.—We annex a drawing of a dibble much used in France. It makes two holes at the same time, and prevents the necessity of stretching the garden-line so often when planting in rows; the line need only be changed at every second row.

VARIETIES.

JAPANESE GARDENING.—We have recently had an opportunity of comparing the horticulture of Japan with that of this country. A gentleman residing in Yeddo—the London of the eastern world—has sent home some of the best specimens he could procure of the much-prized plants used in the decoration of the dwellings of the higher classes of Japanese society. We find the principle upon which the horticulturist of that country works as different as possible to that which actuates the British gardener—as widely do they differ from each other as the islands in which they originated. The great aim of the Japanese gardener is to make a little, dwarfed, and stunted tree look as old, as gnarled, and twisted as possible; he strives to make the plant of a foot or two in height rival in this respect the monarch of the forest, whose moss-covered stem has braved the storms of a hundred winters, but which has, nevertheless, suffered from the effects of a thousand accidents. In one case, a little Coniferous tree—some species of *Pinus* which, in this condition, it is impossible to identify—has had its roots crammed into a little porcelain flower-pot; its stem has then been bent backwards and forwards in a zig-zag way, and tied in a hundred places with narrow strips of bark (the produce probably of some kind of *Daphne*). The Japanese are very skilful in the art of grafting, as is shown by several of these plants. In one example an old *Podocarpus* stem has been cut off horizontally, and three or four scions of an oval-leaved species introduced; as these shoots grew, they were trained downwards, for the double purpose of hiding the stem, and at the same time checking the luxuriance of the plant. The dark green glossy leaves of this specimen are on several of the shoots striped with white.

AMERICAN MISTLETOE.—This is a parasitic plant which grows on hard-wood trees that have rough bark, in some sections of the country, particularly in the lower part of the valley of the Ohio, and along the Mississippi. The Oak and Elm seem to furnish the best support to it. Its leaves remain green through the winter, which gives a striking effect in contrast with the bare branches of the trees on which it grows; but it seems to injure the trees. We have noticed that the branches of those on which the parasite has been growing for the longest time, and in the greatest abundance, have become gnarled, and apparently unthrifty; their decay, in some instances, being hastened from this cause. The *Ohio Cultivator*, in reply to a correspondent who asks if the Mistletoe would not improve the appearance of certain trees in winter, says—"The seeds are deposited by birds upon the trees where they alight, growing in form and size much like a corn basket inverted, with a single short stem like that of a toadstool, only that it is of firm wood. If the seeds could be obtained from far-enough south to insure germination, we suppose they could be sprouted in a manurial preparation, and set to grow upon the rough bark of trees in damp situations. To our eye, the American Mistletoe has no more picturesque beauty than a big squirrel's nest in a tree top." This plant is of a different species from the European Mistletoe, and we quite agree with our contemporary that it adds no beauty to the trees on which it grows.—(*Boston Cultivator*.)

[Can any of our readers inform us what is the botanical name of this parasite?—EDS.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE planting out of Broccoli, Winter Greens, Kales, Cauliflowers, and Cabbages, to be carried on at every favourable opportunity, so that every vacant place may be soon filled up. *Asparagus*, now is a good time to apply salt to the beds, about 1 lb. to a square yard. Stimulants applied now will enable the roots to lay up a good store of organised matter for another season; and, therefore, in addition to salt, occasional applications of liquid manure to be given, the beneficial effects of which will be perceptible in the autumn and more especially in the spring, by increasing the size and productiveness. *Beans (Broad)*, make another sowing, but previously to doing so soak the seed in water and water the drills. Pinch off the tops of those that are forming their pods. *Celery*, the trenches for the main crops to be prepared; if the trenches are made between the rows of Peas, the shade from the Peas will be beneficial to it in its early stage, and the Peas will be done bearing and can be removed by the time they are likely to be injurious. *Dwarf Kidney Beans*, make a good sowing for the autumn, and water the drills previously to planting them. *Peas*, sow some of the quick-bearing sorts for autumn use; steep the seed and water the drills as advised for Beans. Continue to stick the advancing crops. *Radishes*, make a sowing for succession; if the ground is dry water it immediately after sowing, and shade it by mats or other means to prevent evaporation. *Scarlet Runners*, a sowing may yet be made to come in late in the autumn. Stick the advancing crops. *Tomatoes*, keep them well thinned out and nailed to the wall or fence. *Turnips*, if the weather is dry it will be necessary to water the late sowings, and every time after doing so to sprinkle them with any kind of dust to prevent the ravages of the fly.

FLOWER GARDEN.

Attend to tying up herbaceous plants that are tall or showing flower, such as the Rockets, Pæonies, Delphiniums, Lychnis, &c., in order to prevent them from being injured by the wind. Propagate choice Roses, Pinks, Pansies, and Double Rockets; and mow grass lawns often during this growing weather. An acquaintance with the different species of bulbs will direct the cultivator how he should treat them, some species, for instance, form new bulbs by the side of the old ones, and in course of time become crowded and weak and cease to bloom. Others form the new bulbs under the old ones, and at last get so deep as to produce similar effects. Others again form their new bulbs over the old ones, and become elevated above the surface of the ground and are destroyed by the hoe or the frost. All those that require taking up, such as Ranunculuses, Hyacinths, Tulips, &c., should be taken up and housed till autumn.

FRUIT GARDEN.

Strawberries will require liberal applications of water if the

ground is dry. Thin out the young shoots of Raspberries. Pinch out the tops of the young shoots of Figs. The young wood of wall trees to be frequently nailed in. Remove all suckers from Filberts as they appear, examine the young fruit and look after caterpillars as they are making sad havoc in some places.

STOVE.

Besides the daily routine of watering, shading, giving air, and an occasional shift to some more promising specimen, there is little else to be remarked on just now. The climbing plants to be attended to, see that they are properly trained either to stakes or trellises, some of them may require stopping to throw out more shoots. The beauty of these plants depends in a great measure upon the training they receive during the season in which rapid growth is going on. Regulate Orchids so that those requiring most humidity or air may occupy those positions most suitable to them. Avoid watering those that are not in active growth. Some of the free-growing kinds will be benefited by increased pot room, and those on blocks of wood and in wire baskets may have a little additional moss placed over the roots. When vigorous growth is going on never allow the young and succulent roots to perish for want of moisture.

GREENHOUSE AND CONSERVATORY.

Keep the greenhouse plants moist by frequent syringings, turn the plants round from time to time that they may not get one-sided and allow them to have plenty of room on all sides. A lot of the best Scarlet Geraniums to be selected for blooming next winter. These to be grown rapidly and to be frequently stopped, towards autumn they will become rather pot-bound, they must not, however, be shifted, but merely hardened in a very exposed situation until the end of September, in order to get them sturdy and short-jointed; by such means they will become objects of great interest all the ensuing winter. Cut down Pelargoniums after blooming and put in the shoots for cuttings. By pinching off the blossom-buds of the young Pelargoniums a late bloom can be secured. The Perpetual and Bourbon Roses which have been forced, place in a cool situation for the purpose of repressing further activity. After a season of rest the soil to be shaken from them and all decayed roots removed, after which they should be potted in fresh soil, removed to the protection of a cold pit and there plunged. W. KEANE.

DOINGS OF THE LAST WEEK.

"LONG-LOOKED-FOR come at last." The frequent drizzles of rain that refreshed the foliage, but did little more than lay the dust, came down in more earnest on the 8th, and on Sunday night and Monday morning so copiously as to refresh the earth, giving good hopes for a hay crop, and just the very thing for all fresh-planted flowers and vegetables in the garden. So gently, too, did the rain fall, that there was plenty of time for one shower thoroughly to soak in before another came. We were from home a few hours on Monday morning, and we never recollect seeing a stronger confirmation of the importance of shading or of sprinkling the foliage in sudden extremes from dull weather to sunshine. The sun shone out for a short time after breakfast on Monday; and though the plants were quite damp enough at the roots, yet almost everything in the houses began to flag more or less. Notwithstanding the fine rains of the night saturating the roots of Cabbages and Cauliflowers, even the large leaves of these common vegetables began to hang their heads and droop as if greatly distressed. Even the extra waterings from the heavens could not secure them from feeling the effects of such a sudden transition from a week of dull weather to a few hours of not very bright sunshine. When the sun again was clouded the plants quickly recovered, and would be able to stand a second bright sunshine when it came. More watering at the roots in such a case would have been worse than labour lost. But for a syringing, or a little shade, many a tender leaf might have been scorched up or shrivelled.

The rain was just the thing for the winter Greens turned out, and a great temptation to turn out everything for which room could be had. We find from a small kitchen garden, which to keep things square must be pretty well always full, that we shall not have room for half we want until early Potatoes and Peas are removed; and in order that the plants may not be drawn and yet be growing, it is a good plan to dig a bit of ground shallowly, mix rotten leaf mould or decayed dung for

2 inches or 3 inches on the surface, and then prick out the plants 3 inches or 4 inches apart. Here they will make nice, sturdy plants, and, if desirable, will lift with a ball when their future home is made ready for them. Mowed down the winter Spinach, intending to dig it down and plant the space with early Coleworts, and Cabbages, giving them about a foot from each other. Finished thinning Carrots, Parsnips, Onions, and the earliest Beets. Sowed the last of the Marrowfat Peas for the season, as the Ne Plus Ultra, Jeye's Conqueror, Veitch's Perfection, Harrison's Perfection, &c., and staked up all the previous sowings that were high enough. The old nurserymen used to tell gardeners "to sow thick and thin quick," but if seed is good, nothing more surely defeats its purpose than sowing large-growing Peas thickly; but this season the advice even as respects them would have been suitable, for never did Peas come up weaker (of the better sorts) and so few of them too. I have reason to be glad that a few home-saved seeds, though anything but a good sample, came up well and vigorous, whilst some kinds that came from the most respectable seedsmen, and fine samples too, rotted in the ground. Much of the seed I fear was too old, though most likely thoroughly unknown to the tradesmen. Great complaints have been made of *Scarlet Runners*, and we find that in our own case, the seed rotted in the ground considerably, though covered not more than an inch. One of our neighbours had a fine lot of seed two years old, and even that came thick as could be, and he had the satisfaction of helping others not so well off.

Great complaints have also been made of bad seed in *Dwarf Kidney Beans*; but here they never came up more regularly and better, though I never knew them lie so long in the ground before moving; and I have no doubt that some of the failures were owing to early sowing, placing the seed rather deep, and the extra cold, wet condition of the earth until of late. Will sow directly the last lot for the season out of doors. Have turned out under the protection of calico and glass merely, a nice lot just beginning to swell, others showing bloom, and another succession to them to come in before the first crop out of doors, and when the first of these protected crops are fit to gather, will clear out the remainder from pits, &c., that have borne well all the season, and would continue till the end of it, if we could spare them the space. Sowed also Spinach, Turnips, Radishes, Lettuces, Cauliflowers, Onions, &c., for succession.

Having been rather disappointed last season in ridge Cucumbers and Vegetable Marrows, turned out strong plants in a bed formed with mowings of grass, long dung, half decomposed dung, &c., all well mixed together, and put up for fully a yard in height so as to yield a gentle continuous bottom heat, putting over that 1 foot of rotten leaves, and then 1 foot of soil, and turning out strong plants at once and laying them down, putting a hand-light over the collars of the plants in some cases, and a spare sash in others, and a rail back and front until they are growing freely. In fine seasons such care is not necessary; but the last cold autumn should give us a note of caution. Put some dung together and a few droppings on the top, for a *Mushroom-bed* in an open thatched shed, similar to what we did a few weeks ago, as such a place is more suitable in summer than any Mushroom-house, unless it be sunk beneath the ground level, or be in a cellar or something of that kind. This enables us to clear out the Mushroom-house; and thus to a great extent, by means of washing with hot water and smoking with sulphur, to get rid of all sowbugs and other insects before commencing again in autumn. Those interested in rough Mushroom-beds may look back for the Number in which I spoke of making a bed with stubble, long dung, and a few droppings on the top. I was rather surprised it cooled down so nicely and so gently, and enabled us to spawn it so soon. After spawning, a little horse-droppings and a few sheep-droppings—say 1½ inch in all, were spread on the surface and beat down; and as this just made a very gentle heat, after a couple of days or so, the soil, 2 inches or a little more was put on well kneaded, watered, and smoothed on the surface. All still kept right, and as the trial stick showed rather less than more heat than was necessary, a slight covering of hay was thrown over it. This seemed just to make all right, but in four or five days after a close, muggy night, the bed got excessively hot, and all covering was at once removed, when it soon cooled. Since then it has taken upon itself to heat suddenly and cool suddenly three or four times, which is rather uncommon for these beds, and I can account for it on no other consideration than the dressing of the sheep-dung on the surface being rather thick, and, perhaps, the bottom of the bed being so loose as, independently of our close covering of the top, the air might

gain entrance and ever and anon produce fresh fermentation.

We have examined the bed, and on the whole find the spawn working pretty well and promising a fair crop, but after a few hours more continuance of the same heat, which we found it attain in less than twenty-four hours, and we would have not given a farthing for the produce of the bed. Even after spawning and earthing, Mushroom-beds require watching, and this is the lesson the above circumstance is designed to teach. We have no doubt that more failures arise from heats than colds. If the bed is rather cold, a covering on the surface will retain heat into it, and, when the spawn is working, that will make heat of itself. The bottom heat for a Mushroom-bed should average about 80°, seldom above it. The atmospheric heat should average 55°. When close, firm Mushrooms are desirable, a few degrees less are better than a few more; in no case should it exceed 60°. Those who take notes, will find the Mushroom does best out of doors in the fields, when the temperature approaches these conditions. In autumn the soil is warm, and the night air is cool.

After trying many plans in summer, such as inserting the spawn in beds of Cucumbers, Vegetable Marrows, &c., I have come to the conclusion that, next to a place under ground, a shady shed, or an open space under the thick shade of trees, and yet where means can be taken to throw off the rains, and heavy drops that come from them, is best at that time for securing Mushrooms in good fleshy condition. The shed I have I thatched with straw on purpose, the wall is at the back, and the front is open or partly shut with thin strawed hurdles. Without a shed I would use small ridges in summer, say dung well prepared, 2½ feet wide at base, and 2 feet to the ridge, spawned on each side, covered with 2 inches of soil and a slight sprinkling of hay, kept a little moist in hot dry weather. A foot or two above this, we should like a waterproofed covering of some kind of boards or of canvas, painted outside white. The covering is another security against heat and the falls of heavy rains, and yet the air circulates freely under all. In close Mushroom-houses in summer, the maggotty and thin appearance of the Mushrooms is owing to excessive heat, the want of air, or the giving that air in rushing currents. At such times they seem to dislike draughts as much as the tenderest-reared lady.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

DISEASED PEACHES (*A Young Gardener*).—Your cracked, dry-gongrened Peach intimates that there is a deficient supply of sap to the tree which bore it; and as there are many on the same tree similarly attacked, it is evident that there is something wrong at the roots. These have descended into an ungenial soil, or the soil of the border in the house in which they grow is too poor or too dry. In the latter case liquid manure and mulching would be the best applications.

CHECKING CINTEROUS PLANTS (*B. W.*).—This, effected by lifting them annually in autumn, will not prejudice their future growth if not continued above four or five years. Six feet high is sufficient for the wire-netting used for confining poultry, provided you do not put a bar of any kind along the top of it, poultry seeing the bar would try to fly up to roost upon it. You cannot keep young standard Apple and other fruit trees within dwarf bounds, by pinching and stopping them.

INDEFINITE QUESTION (*A Young Beginner*).—Your question is too wide and indefinite for us to answer you. "What fruit and flowers, plants and creepers would grow at Tipton, in Lancashire?" And what is "Cadluck?" But all grasses and weeds, with no seed on them, are good manure.

VARIORS (*G. S. A.*).—The *Phlox verna* should be staked directly; but to get fine plants in pots we would lift and repot the older plants, and keep them in a shady place for a time. They will flower very early in spring, if merely kept under glass. Shift the *Cypripedium spectabile* as it begins to grow, give a little cowdung and sandy loam to the peat, and weak manure water as long as it keeps growing. We would not shake all the soil from the roots of *Cerasus japonicus* nor *Deutzia gracilis*, but rather keep all that will adhere to them; and, for such a purpose, we would prefer potting in October to potting at Christmas. At the latter time we should expect many of the buds of *Cerasus*, and *Deutzia* too, to drop, even if the soil was not shaken away as you propose.

SEEDLING AQUILEGIAS OR COLUMBINES (*Mr. Ransom*).—Your Aquilegias are the finest we have yet seen in that family; two of them partake of the colour of Skinneri with a mixture of yellow; another pair look as if glandulosa or alpine blood was in them, with the white turned to a beautiful primrose tint. There are two shades of purple, edged with yellow, and there is a double deep yellow with light purple spurs, and a light single yellow with lilac spurs; all are large, and the deeper red one after Skinneri with the

bright yellow edges, is the richest in combination of colour. They are most beautiful border flowers certainly.

HEATING SMALL GREENHOUSE (A. F.).—The "slow combustion" apparatus you speak of is very efficient, but for so small a place we should use an Arnott's stove. Dees live through the winter in wooden hives in Scotland, very much further north than you reside. At the same time, there is no doubt that straw hives are warmer than wooden hives.

NAMES OF PLANTS (J. H. Wilson).—1, *Manettia glabra*; 4, *Cattleya Harrisoniae*; 8, *Elæia hyacinthina*; 9, *Pothos violacea*. The rest are obscure weedy Orchids unknown to us. (*E. D., Chester*).—*Petasites vulgaris*. It flowers in spring before the leaves appear, and is very fragrant. (*R. Phipps*).—1, *Bunium flexuosum*; 2, *Veronica Baccabunga*; 3, *Veronica polia*; 4, *Cherophyllum sylvestre*. (*W. H. Cooke*).—1, *Lychnis diurna*; 2, *Veronica officinalis*; 3, *Allium ursinum*. (*M. F.*).—*Duranta Ellisia variegata*, a stoveshrub as far as can be judged from leaves only. (*J. Fair*).—It is some Caryophyllaceous plant certainly, and apparently some species of *Silene* or *Dianthus*, and, therefore, an accidental weed if *Fera* seed was really sown. No doubt it is an outdoor plant. (*G. S. A.*).—1, *Anthericum lilastrium*; 2, *Ceanothus buxifolia*; 3, *Thalictrum aquilegifolium*.

FLOWER SHOWS FOR 1861.

JUNE 19th and 20th. BRIGHTON AND SUSSEX FLORICULTURAL AND HORTICULTURAL SOCIETY. Sec., E. Carpenter.

JUNE 25th. ROMFORD. (Plants, Flowers, and Fruit.) Sec., A. Cooper, Romford.

JULY 3rd. PORTSEA ISLAND. Sec., H. Hollingsworth, Southsea.

JULY 6th. CRYSTAL PALACE. (Rose Show.) Sec., W. Houghton.

JULY 10th. ROYAL HORTICULTURAL SOCIETY. (Rose Show.) *Garden Superintendent*, G. Eyles.

JULY 18th. TOWCESTER FLORAL AND HORTICULTURAL SOCIETY. Sec., T. B. Rodhouse, Towcester.

JULY 18th. PRESCOT. Sec., J. Beesley.

AUGUST 9th. BELFAST ROYAL BOTANIC AND HORTICULTURAL SOCIETY. (Plants, Fruits, and Vegetables.) Sec., George A. Cartwright.

AUGUST 14th. PORTSEA ISLAND. Sec., H. Hollingsworth, Southsea.

SEPTEMBER 2nd. HECKMONDWIKE. (Floral, Horticultural, and Agricultural.) Sec., G. Kelley, Heckmondwike.

SEPTEMBER 4th and 5th. CRYSTAL PALACE. (Dahlias, Cut Flowers of other descriptions, and Fruit.) Sec., W. Houghton.

SEPTEMBER 11th. ROYAL HORTICULTURAL SOCIETY. (Dahlias and other Cut Flowers.) *Garden Superintendent*, G. Eyles.

SEPTEMBER 18th and 19th. BRIGHTON AND SUSSEX. Sec., E. CARPENTER.

NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums.) *Garden Superintendent*, G. Eyles.

NOVEMBER 12th and 13th. STOKES NEWINGTON CHRYSANTHEMUM SOCIETY. Sec., W. T. Howe.

NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show.) Sec., W. Houghton.

N.B.—Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

JUNE 19th. THORNE. Sec., Mr. Joseph Richardson. Entries close June 12th.

JUNE 19th, 20th, and 21st. COALBROOKDALE. Secs., Messrs J. B. Chune, and Henry Boycroft, Coalbrookdale.

JUNE 25th. ESSEX. Sec., Mr. W. R. Emson, Slough House, Ilalstead, Essex.

JUNE 28th. DRIFFIELD. Sec., Mr. R. Davison. Entries close June 22nd.

JUNE 28th and 29th. TAUNTON. Sec., Mr. Charles Baillance. Entries close June 17th.

JULY 3rd, 4th, and 5th. BLACKPOOL and WEST LANCASHIRE. Sec., Mr. E. Fowler, jun., Market Street, Blackpool. Entries close June 30th.

JULY 18th. PRESCOT. Sec., Mr. J. Beesley.

AUGUST 26th, 27th, 28th, and 29th. CRYSTAL PALACE SUMMER SHOW. Sec., Mr. W. Houghton.

SEPTEMBER 3rd. POCKLINGTON (Yorkshire.) Sec., Mr. Thomas Grant. Entries close August 26th.

SEPTEMBER 24th. BRIDGORTH. Sec., R. Taylor, Bridgorth.

DECEMBER 2nd, 3rd, 4th, and 5th. BIRMINGHAM. Sec., Mr. J. B. Lythall, 14, Temple Street. Entries close November 1st.

DECEMBER 11th, 12th, 13th, and 14th. CRYSTAL PALACE WINTER SHOW. Sec., Mr. W. Houghton.

N.B.—Secretaries will oblige us by sending early copies of their lists.

BIRMINGHAM POULTRY PRIZE LIST FOR 1861.

Time certainly goes faster than it used to do. It was only the other day, we, in common with many friends, were in Bingley Hall, rejoicing and wondering somewhat at the crowds of distinguished company that testified by their presence, and by their contempt of unfavourable weather, the undiminished interest they feel in our favourite pursuit; and now the prize list for December, 1861, is put into our hands, we plead guilty to a desire to speak well of the Birmingham and Midland Counties Show. It has a great claim on the sympathy of every one: it is successful, and it can point to years of past glory as the earnest of what it will do again, and as the assurance that everything contained in that long red-lettered prize list will be properly carried out. The Dorkings make eight classes, and here Mr.

Martin Billing liberally offers a piece of plate, value five guineas, for the best pen in any class. Mr. Henry Wade for adult Cochins; Mr. James Cattell for chickens; and Mr. Greensill for Game, follow the good example.

There are ninety-five tempting classes with prizes as thick as "leaves in Vallembrasa," courting the best attention of amateurs. There is a class for Pheasants, one for Ornamental Water Fowl, and one for young Geese. These are great improvements, and they are in keeping with the progress of our times. A quaker-like devotion to staid colours seems to have been on the wane ever since the decoration of the Crystal Palace in 1851, by Owen Jones. People took a liking to colour; and just as mauves, cerises, and magentas have displaced the doves, drabs, browns, and slates in our ladies' dresses, so utility is sought in poultry, combined, if possible, with beauty of plumage. Ornamental Ducks and Pheasants will discourse eloquently on this subject by their presence; and there was a time when the Turkey, Guinea Fowl, and Pheasant were as much novelties as many a bird will be at Bingley Hall.

The Pigeon classes have been strengthened, and they needed it much. A first prize of £3 has been added to each. This will, we hope, increase the entries of these beautiful birds.

The greatest change of all remains to be noticed. It has often been a difficulty, and in many instances an insurmountable one, to get three perfect hens for a pen; those who have not tried have little idea of the task, because ordinary fowls are not at home at Bingley Hall, and many have thought to demand three hens or pullets was to restrict the Show to the large yards. In this as in every other point where the public taste should be consulted, the Committee and Council of the Birmingham Show meet the wishes of their friends, and it is announced that at the next Exhibition each pen will be composed of two instead of three hens or pullets. This is a great boon, and we trust it will be appreciated by every amateur in the United Kingdom.

The period that must elapse between this notice and the Show itself, will allow us time and space for more than one recurrence to it; but our feeling in favour of our first poultry love is so strong, and the claims its managers have on the public are so well founded, we never delay after receipt of the prize list to bring it before the public, to raise our voice in its favour, and to bespeak all the support it deserves so well.

EGGS UNPRODUCTIVE.

IN February of this year I brought a Brahma cock and three hens, which are first-class birds. I have had six sittings at different periods, the last of which was due this day; the whole batch have proved rotten. Can you point out the cause?—A SUBSCRIBER.

[It is almost impossible to tell you what may be the cause of your failure, and we were never more disposed to collect and publish the curiosities of poultry than we are now. We have in our time, met with unaccountable vagaries in other animals. An excellent friend of ours breeds horses largely; till within the last three years, there had not been a colt bred on the farm for half a century—all were fillies. We bred the Silver Grey Rabbits; among many does there is one that always has one or more Himalayan young in the litter. This has happened four times; previous to that, during two years she never had any. On speaking of this to other breeders we find the same thing has happened to them. We will now speak of our Cochins experience of this year: Our early stock was about fifty hens and twelve cocks, they were divided into several walks of one cock and four hens; but as all were considered equally good, they were shifted at times. Our first eggs came off in the early part of January—five chickens out of eighteen eggs; we were very dissatisfied, we made some alterations and tried again—worse result—none hatched at all. We bought fresh cocks, we altered the pens, in some we increased, in others we decreased the proportion of hens to cocks, still the same result; in fact, we have tried everything we know, and the average of our Cochins eggs has not been one chicken in ten eggs. At the same yard are four other breeds, all of which have hatched wonderfully well, far better than usual, whole sittings came off day after day. We are not discouraged, we intend to sit our hens again in July, and we advise you to do the same. Having tried every plan, scheme, and change that we know of without success, we have only to tell you that naked and unsatisfactory truth, and to lament you should be as badly off as ourselves.]

THE CANARY AND THE BRITISH FINCHES.

(Continued from page 209.)

12.—THE COMMON OR HOUSE SPARROW (*Fringilla domestica*.)

French, Le Moineau. German, Der Hous Sperling, or Spatz.

THE common or House Sparrow is a bird so common and generally spread over Europe, that it is at least known to every one; yet its habits have been but partially investigated.

On a closer examination the plumage of the male will be found much prettier than is generally thought. The head is dark, the top being as if powdered with grey; a reddish-brown mark behind the eyes; the cheeks ash-grey; a spot beneath the bill, black; and a larger spot on the front of the neck, in which the feathers are black with grey edges; but as spring advances these grey borders are much worn off, and the black bib appears larger; the back of the neck dark grey; the back reddish-brown with longitudinal black spots; the wing covert-feathers are reddish-brown, one row having white edges that form a white bar on the wing; the quill-feathers of wings and tail are dark dull brown; the under parts of the body greyish-white.

The female is much less diversified in colour, the upper parts being of a dull greyish-brown, the under parts dirty white; a lighter stripe enlivens the face, and some black spots the back.

The young in their first plumage closely resemble the hen; but the young cocks may be recognised by examining the feathers on the throat, in which the down at their base will be found dark, and their backs are rather more reddish.

Varieties in colour are not uncommon, of which may be named white, buff, light grey, slaty, and black; also pied specimens are sometimes met with. I once took from a nest a beautiful white Sparrow, all the feathers of which had a narrow yellowish border. I reared it by hand, but unfortunately it died in the moult, all the new feathers were quite white; so that if it had lived it would have been perfectly white.

The nest is usually built under the eaves of a house, in any hole in the walls, in thick ivy or a hollow tree, and not unfrequently high up in the fork of a tree. It is formed of hay, fine roots, dried weeds, and such materials, and lined with feathers, hair, wool, and pieces of cloth; it is of large size, domed over, and in shape of an egg, with a hole at the small end. The eggs, from four to six in number sometimes, but rarely more, are very various in shade, mostly white, more or less spotted and streaked with grey; but I have sometimes found them only slightly spotted with reddish-brown. Incubation lasts a fortnight, and both parents feed the young almost exclusively on insects. If brought up by hand they may be reared on bread and milk, or bread and eggs, and they then become very tame. Bechstein says, "they will breed in confinement, and also with the Tree Sparrow, and hen Canary." I have, however, never succeeded in breeding mules from them, as they are so exceedingly rough in their courtship. Who has not heard an Irish row among the Sparrows at pairing time, when a dozen or so may be seen pecking, fighting, and chirping over one hen? Such a proceeding would drive all idea of love out of a timid hen Canary. The Sparrow, like the Lark, both bathes in water and rolls in sand or dust.

The song of the Sparrow, if such indeed it can be called, is composed of a succession of sharp broken chirps, devoid of any melody—a sort of excited Sparrow language, which sounds like *chow chow chitter a chow, chee chow chow*. Some writers assert that the Sparrow, if taken young, can be taught to sing. I have tried but without success, and I suspect that it is the Hedge Sparrow or Hedge Accentor which they meant: as Bechstein says, the Sparrow is quite incapable of learning to sing; but that they may be taught to fly in and out of the window, and to come when called. It is also recorded that "a clergyman in Paris had two Sparrows, father and son, which were able to repeat the fourth, fifth, sixth, and seventh commandments; it produced a highly comic effect. When in their quarrels over their food, one of them would gravely admonish the other, *Tu ne voleras pas* (Thou shalt not steal)."
